I_{Ni} = measured fluorescence intensity of the standard reference specimen (Ni) in counts per second [cps]

RSF_i = instrumental sensitivity factor of the analyte i relative to the standard element (Ni)

This formula provides the areal density for the impurity of interest with LOD as given in Section 13.7.

13.7 Calculation of LOD_i, the lowest detectable number of impurity atoms i from a scanned surface, is:

$$LOD_i(t) \equiv 3 \cdot c_{i,VPD} \cdot \frac{\sqrt{N_{bg}(t)}}{N_{netto,i}(t)}$$

where;

$N_{bg}(t)$ denotes the background fluorescence cps, integrated over time (t)

$N_{bg}(t) = I_{bg} \cdot t$,

with

I_{bg} = intensity of the background in cps, and

where;

$N_{netto,i}(t)$ denotes the netto number of the impurity fluorescence [cps], integrated over the time,

$N_{netto,i}(t) = I_i \cdot t$

The equation for the $LOD_i(t)$ can be rewritten as :

$$LODi(t) = 3 \cdot \frac{c_{i,VPD}}{I_i} \cdot \sqrt{\frac{I_{bg}}{t}}$$

14 Bias and Precision

14.1 Relative error of the described VPD-TXRF method must be assessed according to Section 15.11 of this document. Under the given measurement conditions the accuracy of the results is limited by the error summarized in Section 14.2.

14.2 Under given solute amounts and measurement conditions the accuracy of the results is limited only by the recovery rate of the VPD treatment and the scanning solution as described in Section 15.19 of this document. The relative error is to be calculated by:

$$\frac{dc_{i,VPD}}{c_{i,VPD}} = \left(\left(\frac{dR_i}{R_i}\right)^2 + \left(\frac{dRSF_i}{RSF_i}\right)^2 + \left(\frac{dA_w}{A_w}\right)^2 + \left(\frac{dn_{Ni}}{n_{Ni}}\right)^2 + \left(\frac{dI_i}{I_i}\right)^2 + \left(\frac{dI_{Ni}}{I_{Ni}}\right)^2 \right)^{1/2}$$

14.3 Relative error of the reference droplet standard is determined by the error of the micropipette aliquot (V) and of the stock solution (c_S).

$$\frac{dn_{Ni}}{n_{Ni}} = \left(\left(\frac{dV}{V}\right)^2 + \left(\frac{dc_S}{c_S}\right)^2 \right)^{1/2}$$

14.4 The relative error of areal concentrations below the concentration of the calibration standard reference are strongly dependent upon the relative error of the micropipette aliquots. In the given range bias due to crystallization and/or mass absorption can be anticipated to be less than 1% as described in Sections 15.6 and 15.11 of this document.

14.5 Reproducibility of the measurement system must be tested with calibration standard reference in five complete analysis cycles (load-analyze-unload). The standard deviation of the 5 results shall not exceed more than 10% of the theoretical value of the standard deviation of the respective Poisson statistics *Nx*. For long term reproducibility, please refer to Section 2.6.

14.6 The minimum sample size for controlling the wafer-to-wafer reproducibility of the complete procedure must consist of a group of 3 wafers of the very same polishing and/or cleaning batch as described in Section 15.20 of this document. Tolerated standard deviation of 3 groups should be defined by the interested parties.

14.7 In interlaboratory tests (round robin), the reproducibility of the method can preferably be evaluated in accordance with DIN ISO 5725 or ASTM E 691.

NOTE: Report reproducibility in accordance with this document. Calibration accuracy was found to be within 10% relative standard deviation for K, Ca, Ti, Cr, Fe, and Cu among five TXRF stations as stated in Section 15.21 of this document. W and other compounds forming volatile fluorides shall not be analyzed after VPD because of low recovery rates.

SEMI M34-0299
GUIDE FOR SPECIFYING SIMOX WAFERS

1. Purpose

1.1 This guide is for specification of SIMOX (separation by implantation of oxygen) wafers with less than 0.5 μm silicon film thickness used for semiconductor device manufacture. These specifications define the generic characteristics of SIMOX SOI wafers; the specific values for measured parameters will be determined by agreement between the user and supplier for the application. By defining parameters, inspection procedures, and acceptance criteria, both users and suppliers may uniformly define product characteristics and quality requirements.

2. Scope

2.1 The primary standardized properties set forth in this specification relate to physical and electrical characteristics of SIMOX wafers.

3. Referenced Documents

3.1 *SEMI Standards*

SEMI M1 — Specifications for Polished Monocrystalline Silicon Wafers

SEMI M22 — Specification for Dielectrically Isolated (DI) Wafers

3.2 *ASTM Documents*[1]

Practice E 122 (vol. 14.02) — Practice for Choice of Sample Size to Estimate Average Quality of a Lot or Process

F 154 (vol. 10.05) — Standard Practices and Nomenclature for Indentification of Structures and Contaminants Seen on Specular Silicon Surfaces

F 523 (vol. 10.05) — Standard Practice for Unaided Visual Inspection of Polished Silicon Slices

3.3 *Other Standards*[2]

ANSI/ASQC Z1.4 — Sampling Procedures and Tables for Inspection by Attributes

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohoken, PA 19428-2959

2 American Society for Quality Control, 611 East Wisconsin Avenue, Milwaukee, WI 53202

4. Terminology

4.1 *Acronyms*

4.1.1 *BOX* — Buried Oxide

4.1.2 *SIMOX* — Separation by Implantation of Oxygen

4.1.3 *SOS* — Silicon on Sapphire

4.2 *Definitions*

4.2.1 *buried oxide* — The oxide layer that is formed by the oxygen implant.

4.2.2 *SIMOX layer* — The thin silicon, layer above the BOX. This is also referred to as top silicon or superficial silicon.

4.2.3 *substrate* — The supporting material: silicon for SIMOX.

5. Requirements

5.1 The complete specification for the starting substrate to produce SOI wafers includes all general requirements of SEMI M1 or SEMI M3, as applicable.

5.2 In addition, the parameters listed in Table 1 shall be specified, as applicable. For example, specification of BOX thickness is not applicable for SOS. The specific values for parameters listed are to be specified by agreement between user and supplier for specific uses and specific wafer technologies.

5.3 The parameters of Table 1 apply to the final SOI wafer. Parameters for the starting material may be specified by agreement between user and supplier using other standards (e.g., SEMI M1 or SEMI M3, as appropriate). Additional parameters shall be negotiated between user and supplier, as needed.

6. Sampling Plan

6.1 Unless otherwise specified, ASTM Practice E 122 shall be used. When so specified, appropriate sample sizes shall be selected from each lot in accordance with ANSI/ASQC Z1.4. Each quality characteristic shall be assigned an acceptable quality level (AQL) of lot tolerance percent defective (LTPD) value in accordance with ANSI/ASQC Z1.4 definitions for critical, major, and minor classifications. If desired and so specified in the contract or order, each of these classifications may alternatively be assigned cumulative AQL or LTPD values.

Inspection levels shall be agreed upon between the user and supplier.

7. Test Methods - Dimensions

7.1 *SIMOX Layer Thickness Measurements*

7.1.1 *Measurements Methods* — Two non-contact, non-destructive optical characterization techniques, spectroscopic reflectometry and spectroscopic ellipsometry, have proven useful for SIMOX layer thickness measurements. Both techniques use reflected light to allow deduction of the thickness and refractive index of thin film layers. In both cases, film thickness and index of refraction data must be "backed out" of the measured optical data by a process of successive approximation. In both cases, the fitting procedure is more straightforward and more accurate the as-annealed SIMOX wafers with abrupt silicon/oxide interfaces than for the implanted SIMOX wafers with extended interface zones. Silicon islands and interface nonuniformities make these techniques problematic for SIMOX wafers with oxygen implant doses below the "stoichiometric dose", roughly 1.6×10^{18} O^+/cm^2 for a 375 nm oxide layer.

7.1.1.1 The measurement strategy is to make a detailed measurement with an accurate fit on at least five wafer sites, including the center as illustrated in Figure 1. The number of wafer sites to be monitored should be agreed on between customer and vendor. Generally, the greater the variability relative to the mean, the larger the number of sites that should be monitored. In each case, the measurement system supplies a "goodness-of-fit" parameter which indicates a level of confidence in the fit to the measured data.

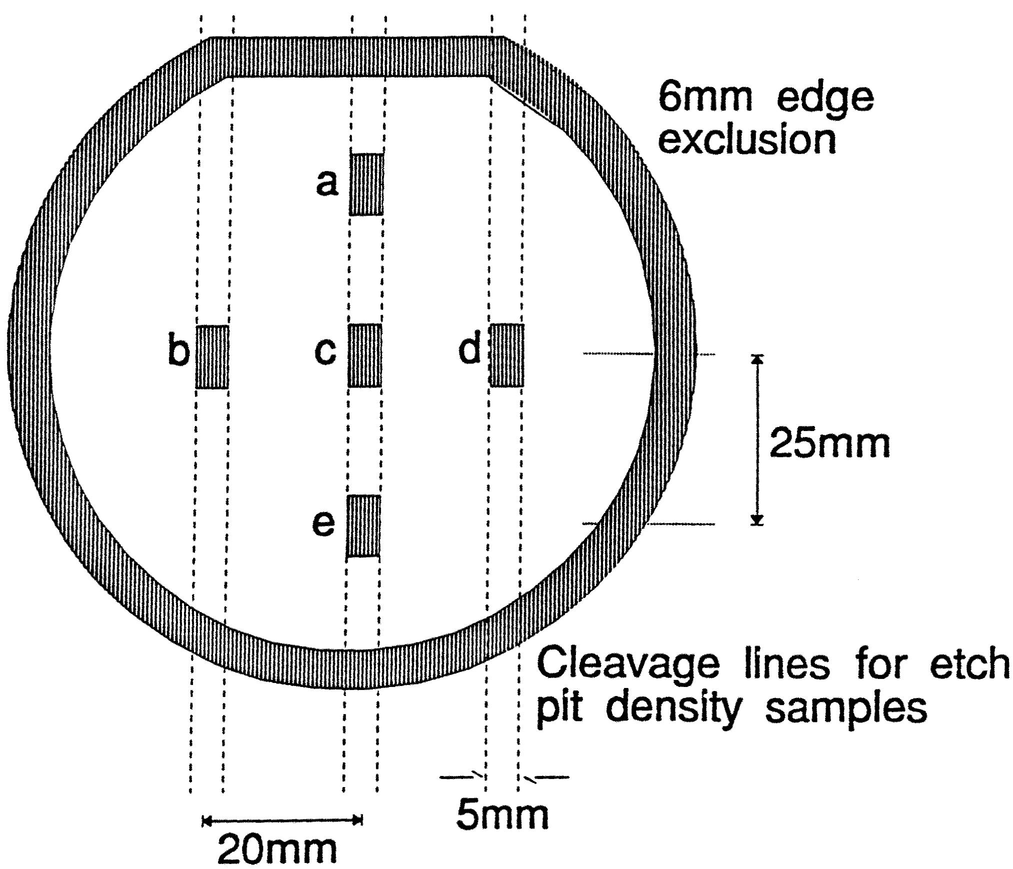

Figure 1
Schematic of Measurement Sites, Cleavage Lines, and Edge Exclusion for 100 mm SIMOX Wafer Inspection

7.1.2 *Spectroscopic Ellipsometry Measurement* — In this measurement, white light from a xenon arc lamp passes through a polarizing rotating filter and illuminates the sample site under study; reflected light passes through an analyzer to a monochromator and photomultiplier detector. For each wavelength, reflectivity oscillates with polarizer rotation; the magnitude and phase of reflectivity changes are measured to determine ellipsometric angles, δ and ψ. The two measured spectra are fit by successive approximation to allow determination of the silicon and oxide layer thickness and oxide composition. Ellipsometry measurements are only specified for the annealed SIMOX wafers. For spectroscopic ellipsometry, the choice of instrument and associated model and fitting parameters affect the confidence-of-fit, so they should be taken into account in the user/supplier agreement. For example, with the SOPRA SE system, the goodness-of-fit error estimator shall be less than 0.025 for accurate structural models.

7.1.3 *Optical Reflectance Measurements* — In this measurement, light from a xenon arc lamp passes through a grating monochromator and illuminates the sample site under study; reflected light is gathered by an intrinsic silicon detector. Specular reflectivity is plotted as a function of wavelength from 0.4 micron to 1.1 micron. The analysis proceeds by making successively better approximations to the oxygen content, index of refraction, and absorption of each layer until an acceptable fit is achieved. Measurements are made with a reflectance mode optical interferometer.

7.1.4 *Optical Model Fitting and Correlation* — There are slight, systematic differences between layer thickness measured by reflectance and by spectroscopic ellipsometry (SE). Because of this, user and supplier should specify the actual measurement method to be used. The two methods offer results which are reproducible and well-correlated with each other over a wide range of conditions. If both measurement techniques are used, it is recommended that the reflectance system measurements be calibrated to fit the results of the SE. Figure 2 shows conversion curves for top silicon and oxide layer thickness measurements made with the two measurement techniques.

7.1.5 *Top Silicon Layer Thickness* — See Section 7.1.4 on correlation of reflectance and spectroscopic ellipsometry (SE) measurements. Optical measurements will be made on five wafer sites as shown in Figure 1. Spectra for each site will be fit independently with both the top silicon and oxide layer thickness as adjustable parameters. Both the mean thickness and the uniformity should be specified. Depending on the type of SIMOX wafer being specified, the mean thickness of the top silicon layer will be from 50 nm to 500 nm. Following is an example specification: Mean top silicon layer thickness for the five sites will be 215 ± 10 nm with acceptable goodness-of-fit at all five sites. Top silicon non-uniformity will be less than ± 5 nm.

7.1.6 *Buried Oxide Layer Thickness* — See Section 7.1.4 on correlation of reflectance and spectroscopic ellipsometry (SE) measurements. Optical measurements will be made on five wafer sites as shown in Figure 1. Spectra for each site will be fit independently with both the top silicon and the buried oxide layer thickness as adjustable parameters. Both the mean thickness and the uniformity should be specified. Depending on the type of SIMOX wafer being specified, the mean thickness of the buried oxide layer is from 50 nm to 500 nm. Following is an example specification: Mean buried oxide layer thickness for the five sites will be 380 nm ± 20 nm with acceptable goodness-of-fit at all five sites. Buried oxide uniformity will be less than ± 10 nm.

7.2 *Crystallographic Defect Measurements - Test Methods* — The evaluation of threading dislocation density in the top SI layer will be made by destructive chemical etching and microscopic etch pit density measurements. The appropriate evaluation procedure for given SIMOX wafer, which depends on the threading dislocation density and the thickness of top Si and buried oxide layers, will be determined by the agreement between user and supplier.

7.2.1 Optionally, other crystallographic defects which may be formed in the top Si layer of SIMOX wafers, such as oxide precipitates or micro stacking faults, silicon crystal defects induced by surface particles prior to epi growth when epi is used to increase the thickness of the top silicon. A sampling plan should be established based on experience with the supplier.

7.2.2 Following are examples of the evaluation of threading dislocations in two kinds of SIMOX wafers:

7.2.2.1 Example 1. Threading dislocation evaluation in SIMOX wafers with 200 nm thick top Si layer and 400 nm thick buried oxide: Samples are handled with plastic tweezers throughout the etching procedure. Samples are first stripped of native oxide by dipping in Bell 2 or HF stripping solutions. Immediately after stripping, wafers are dipped in freshly prepared standard Secco Etch: one part (by volume) of a 0.15 molar solution of $K_2Cr_3O_7$ in distilled water and two parts HF (49%). Samples are dipped in the Secco etch until 50 nm of silicon remains, and then they are rinsed thoroughly in distilled water and blown dry. The thickness of the remaining silicon ensures that stacking fault pyramids found in multiple implant material are counted. The threading dislocation density may vary over a wide range, depending on the type of material. The Secco Etch, as described, creates etch pits that appear as dark circles roughly 50 nm in diameter, and pictures should be taken at 2500X to 20,000X magnification in order to unambiguaously identify and count the etch pits. This is suitable for high density defect samples. For lower dislocation densities typical of recent SIMOX material, a third etch in buffered HF (1 HF (49%): 6 NH_4F (40%)) for 10 minutes will etch the buried oxide under each Secco etch pit, creating a characteristic circular shape 2 µm in diameter that can be seen at 500X magnification.

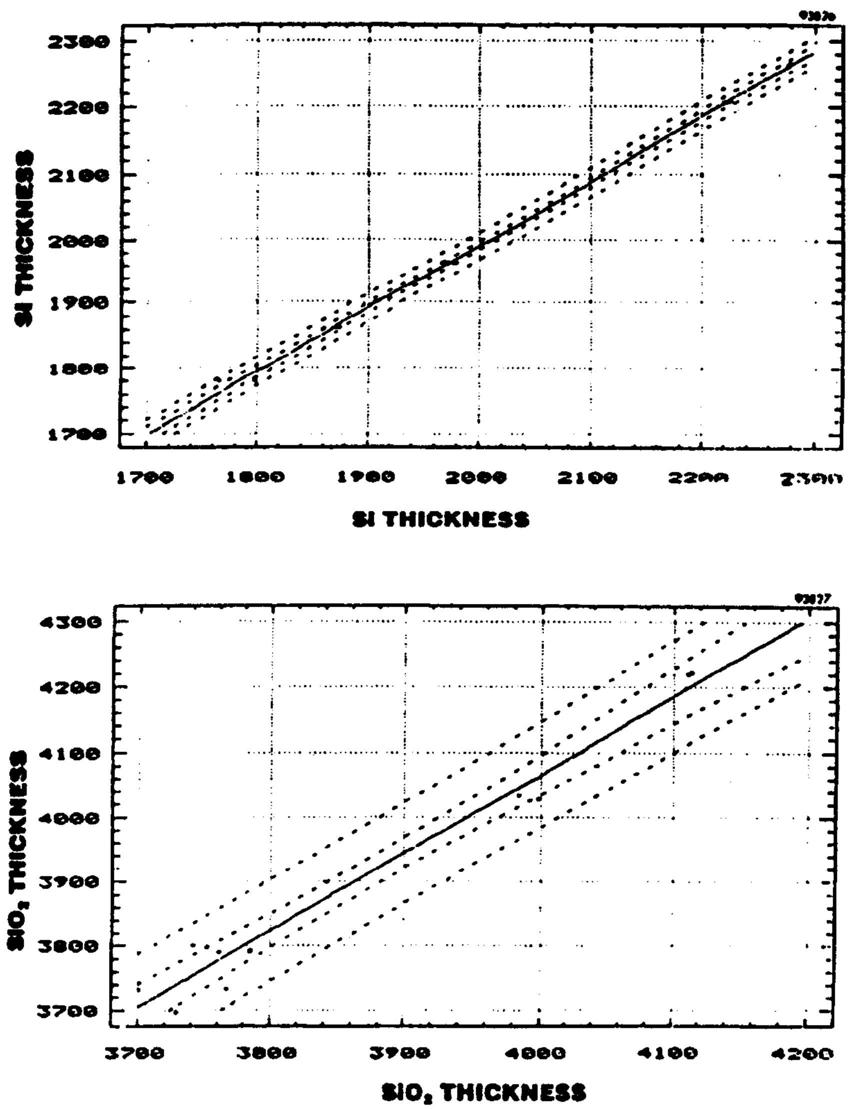

Figure 2
Calibration Curves Relating Reflectance Measurements to Ellipsometry Measurements for Top Silicon and Buried Oxide Layer Thickness

NOTE: Dashed lines are at ± 1 sigma and ± 3 sigma.

7.2.2.2 Example 2. Threading dislocation evaluation in SIMOX wafers with 170 nm thick top Si layer and 100 nm thick buried oxide: Samples are first immersed in HF to remove oxide from the surface. Then the samples are etched for 30 seconds in the solution:[3] 50 ml of HF (49%) plus 80 ml of HNO_3 (61%) plus 160 ml of H_2O [$K_2Cr_2O_7$ 1g + $Cu(NO_3)_2 \cdot 3H_2O$ 4g]. The thickness of removed silicon is about 1/3 of the initial top Si layer thickness, i.e., about 60 nm. After rinsing in water, samples are dipped in HF (49%) for 5 minutes. The HF etches the buried oxide and creates cavities under the etch pits. The cavities are around 10 μm in diameter. Each cavity corresponds to one dislocation threading the top Si layer. The cavities can be seen at 50X magnification.

7.2.2.3 A recommended protocol for the microscopic etch pit density measurement is to take enough pictures to count at least 50 etch pits, and then divide the number counted by the area scanned to get the defect density. The pictures taken should be non-overlapping areas of the sample far from the tweezer marks and far from the edges of the sample. Following is an example specification: Of the five samples prepared from the test wafers, none should have threading dislocation densities higher than 1×10^7 cm $^{-2}$.

7.3 *Buried Oxide*

7.3.1 *Buried Oxide Pinhole Measurements* — Buried oxide pinhole evaluations shall be made by $CuS0_4$ plating or copper decoration methods.

7.3.1.1 In the evaluation done by $CuSO_4$ plating method the wafer under study is placed (front face down) on a paper towel soaked in 20% $CuSO_4$ solution on top of a copper plate. An aluminum plate is placed on the back of the wafer. The copper plate is grounded, and -25 VDC is applied to the aluminum plate. Small (sub-micro Angstrom) leakage currents through pinholes in the insulator cause copper to plate out onto the towel at the pinhole density.

7.3.1.2 In the evaluation done by copper decoration method the top Si layer is first etched off by KOH solution to expose the buried oxide layer. Then the wafer is immersed in methanol and brought downward into direct contact with the gold-coated cathode. A copper mesh as an anode is immersed in the liquid 5 mm above the wafer. Required voltage is applied, such as the electric field in the buried oxide layer is 1MV/cm. The voltage is measured at the oxide surface with a surface voltage probe. Localized copper decorations at pinhole sites in the oxide are observed with a low power optical microscope.

7.3.1.3 Allowable pinhole density depends on the application for SIMOX wafer and will be determined by the agreement between user and vendor. Typical allowable pinhole density is 0.1/cm^2.

7.4 *SIMOX Wafer Surface Inspection*

7.4.1 *Total Reflectance X-Ray Fluorescence Measurements* — The preferred test methodology is described in ASTM F 1526.

7.4.1.1 The instrument provides a map of impurity element distribution. As an example specification, surface contamination for elements within the detection limits (typically S to Zn) shall be less than 10^{10} cm^{-2} per element or < 10^{11} cm^{-2} total.

7.4.1.2 The customer and vendor should be aware that most TXRF systems will contaminate a wafer - slightly on front and significantly on the back. (Reference: DXRC, Denver CO, July 1996, abstract 5.1 "Particulate Contamination from TXRF Instrumentation", Dennis Werho, et al.)

7.4.2 *Automated Particle Counter Measurements* — Automatic production tools are available for accurate particle counting on fully processed SIMOX wafers for particles greater than 0.25 micron. Alternatively, particles down to 0.1 micron can be detected on as-implanted SIMOX wafers prior to anneal. Any specification of particle count should include the point in the process at which the measurement is to be made. Following is an example specification:

7.4.2.1 Instrument settings shall allow detection of particles from 0.3–10 micron size. Maximum allowable particle count, with a 6 mm edge exclusion, is 20 particles greater than 0.25 micron size per 150 mm wafer, or 0.1 particles/cm^2, just prior to shipping.

7.4.3 *Visual and Microscopic Inspection* — Visual inspection techniques will be in accordance with ASTM F 523, when possible, by automatic inspection equipment. Alternatively, slices will be inspected visually under fluorescent light for chips, fractures, scratches, fragmentation, saw marks, grinder marks, and dimples and also under a narrow beam high intensity light (> 6000 footcandles), for fractures, film haze, contamination, and scratches. SIMOX wafers typically exhibit uniform light haze due to light scattering from the rough silicon/oxide interface and from silicon precipitates in the BOX. A light, uniform haze is typically acceptable, while patches of moderate or heavy haze typically are not acceptable.

7.4.3.1 Standards for specification of haze are being developed for bulk silicon. A modification of that

3 Refer to L. F. Giles, A. Nejim, and P. L. F. Hemment, Materials Chemistry and Physics, 1993, vol. 35, p. 129 specification will be required for SIMOX material. It may be necessary to iterate between customer and vendor to agree on specification of acceptable haze.

7.4.4 *Surface Roughness* — Surface roughness is a measure of the microscopic topology of the wafer surface. The effect of this parameter may be in Gate Oxide Integrity (GOI) on MOS devices, depending on the design and process. The measurement of surface roughness is done on an atomic scale by an Atomic Force Microscope (AFM). With AFM, it is suggested that four measurement areas of greater than 2 μm^2 be measured at each of five measurement locations, with the measurement locations distributed as in Figure 1. Because of the expense of this measurement, a sampling plan should be established with the supplier.

7.4.4.1 Standards for specification of surface roughness are being developed for bulk silicon and shall be applicable here when adopted.

7.4.5 *HF Defect Measurements - Test Methods* — Measurement of the microscopic etch pit density following an HF etch is a method commonly used to disclose defects in SOI material. Pitting of the top silicon surface may be present before the HF etch or be caused by HF etching. For this destructive measurement, at least one quarter of a wafer should be used and preferably a whole wafer. The sample is placed in concentrated (49%) HF for 10 to 15 minutes, then removed, rinsed and dried. If there are pits in the SI surface, metal particles embedded in the surface or silicides formed in the top Si layer, the HF will etch the metals/silicides and then etch the buried oxide. This results in a section of the buried oxide being etched out that is 25–50 μm diameter (depending on the etch time) centered on the original pit or particle. The defect density is then measured in an optical microscope using a 5X objective and 10X eyepiece or comparable setup. The sample should be scanned 2–3 times near the center of the wafer if a whole wafer is used to get sufficient statistics. If a piece of a wafer is used, the scan should be adjusted accordingly. The total area scanned should be at least 10 cm^2. Care should be taken to exclude edge density depending on the expected impact on yield versus material cost. A typical specification is that the HF defect density should be less than 1/cm^2.

Table 1. Specification Summary

Parameter	*Reference*	*Example Values*	*Method*
Wafer diameter (D)	ASTM 613	150 mm, 200 mm	Optical comparitor
Wafer thickness	ASTM 533		Thickness gauge
Thickness variation	ASTM 533	< 3 µm	Thickness gauge
Wafer warp	ASTM F 657, F 1390	≤ 30 µm for D = 150 mm	Jig + gauge
Crystal orientation	ASTM 26		X-ray diffraction
a) front surface		(100) ± 1°	
b) back surface			
Substrate type/dopant	ASTM 42		Hot point probe
Substrate resistivity	ASTM 84		4-point probe
Substrate RRG	ASTM 84		4-point probe
Surface Si thickness	Section 7.1.5	50 nm to 500 nm	SE/optical reflectance
Surface Si uniformity	Section 7.1.3	± 5 nm	SE/optical reflectance
Buried oxide thickness	Section 7.1.6	50 nm to 500 nm	SE/optical reflectance
Buried OX uniformity	Section 7.1.3	± 10 nm	SE/optical reflectance
Crystal defect (EPD)	Section 7.2	< 10 E7/cm^2	SEM examination
			Secco etch
Buried OX pinholes		< 0.1/cm^2	a) $CuSO_4$ plating
			b) BOX capacitor @ 1 nA
Metal contamination	Section 7.4.1	total < 10^{11} atoms /cm^2	TXRF
a) per unit area			
b) per unit volume			
Particles	Section 7.4.2	≤ 20 (> 0.25 µm) / wafer	Automated particle counter
Haze	Section 7.4.3	See Table 2.	Visual inspection
Slip	ASTM F 523*	See Table 2.	Visual inspection
Scratches	ASTM F 523*	None	Visual inspection
Chips	ASTM F 523*	See Table 2.	Visual inspection
Surf Spot Discolor	ASTM F 523	See Table 2.	Visual inspection
Foreign matter	ASTM F 523	See Table 2.	Visual inspection
Backside contamination	ASTM F 523		Visual inspection
Surface roughness	Section 7.4.4	5	Atomic force microscope (AFM)
Inclusions	Section 7.4.5		

* The user and supplier may agree on an edge exclusion for these specifications. For example, the area within 6 mm proximity of the wafer edge may be excluded.

Table 2. Example SIMOX Wafer Surface Inspection Criteria

Criterion	*Allow Quantity*	*Description*
Slip	0.3 mm: NONE 0.1–0.3 mm: < 15 mm total < 0.1 mm: OVERLOOK	6 mm edge exclusion
Scratch	NONE	6 mm edge exclusion
Contamination	NONE	Backside
Stain	< 5 spots	< 0.05 cm^2 total area
Edge Chips/Cracks	< 1.5 mm circumferential < 1.8 mm radial	combined length 1 × bright light
Pits and Dimples	< 0.5 mm - 10/wafer > 0.5 mm - NONE	1 × bright light
Haze	Moderate haze - NONE Heavy haze - NONE Non-uniform haze - NONE	Light uniform haze is acceptable. (Iterate between user and vendor.)
Foreign Matter (embedded particles)	< 0.05/cm^2	< 3 embedded particles per 150 mm wafer

Table 3. SIMOX Electrical Parameters

Parameters	*Reference*	*Value*	*Method*
Photoconductivity Lifetime (Backside)	Section 8.1	> 1 msec.	microwave
Photoconductivity Lifetime (Front side)	Section 8.1	TBD	microwave
BOX Breakdown	Section 8.2	> 5 MV/cm	I-V
BOX Pinholes	Section 8.3	< 0.2 cm^2	I-V
BOX Charge	Section 8.4	<	C-V
BOX Surface States	Section 8.5	$< 5 \times 10^{10}/cm^2$	C-V
Doping Density Sub, Surface	Section 8.6	TBD	4-point probe

8. Electrical Parameters

8.1 *Photoconductivity Lifetime* — This is measured by creating an excess of carriers (typically by using a light source) and measuring the slope of the decay curve. Several pieces of commercial equipment are available for this purpose. This requires that polysilicon is not deposited on the backside, as is sometimes done for gettering. Also, surface passivation may be needed for lifetime measurements. Backside measurements indicate the quality of the substrate and can be performed by traditional methods. Frontside measurements are more difficult and must be performed using incident light which can be entirely absorbed before reaching the underlying substrate.

8.1.1 Typically, the sample is placed on a micro-wave wave guide post, forming part of a transmission line circuit. The microwave reflection is determined by the total conductivity of the sample and the conductivity is modulated by an intense light pulse. When the light is turned off, the microwave detects an exponential decay in conductivity from which a decay constant is determined. The photoconductivity lifetime is a result of the recombination velocity at the surfaces, volume recombination in the silicon layer, and any trapping. Measurements are made independently on the front and back sides of the wafer. The mean value on the backside of the wafer will typically be at least 10 microseconds for N-type material and 3 microseconds for P-type material. These values correspond to about a 100 micron diffusion length (SPV value).

8.1.2 The relevance of photoconductivity lifetime to the users requirement should be discussed. The use of this measurement should be negotiated between customer and vendor.

8.2 *BOX Breakdown* — This parameter can be measured with a buried oxide capacitor (BOX-CAP). The buried oxide thickness and the intended application will affect both the test procedure (such as capacitor area and voltage criterion) and the allowable values of measured parameters. These should be determined by agreement between the user and vendor. Example procedure and values for standard evaluation of 400 nm thick buried oxide are given in the following paragraphs.

8.2.1 *Test Structure* — Buried oxide capacitor (BOX-CAP) having an area of 0.01 cm^2 for standard (400 nm) BOX. The electrode material and thickness affect the breakdown phenomena due to thermal effects, and so should be included in the agreement between customer and vendor.

8.2.2 *Test Method: Staircase I-V Measurement* — Voltage is stepped in one-volt increments from zero to 400 volts, or until destructive breakdown is sensed. Tests are done for both bias polarities. The test detects the onset of high field conduction, as well as the point of destructive or massive charge injection and trapping.

8.2.3 *Typical Values*

$J_{ox} < 10^{-8}$ A/cm^2 at $E_{ox} = \pm 2$ MV/cm [onset of hi-E regime]

$E_{ox} > 5$ MV/cm at $J_{ox} = 0.01$ A/cm^2 [break-down/injection]

8.3 *BOX Pinhole Density* — This parameter can be measured with a buried oxide capacitor (BOX-CAP). The buried oxide thickness and the intended application will affect both the test procedure (such as capacitor area and voltage criterion) and the allowable values of measured parameters. These should be determined by agreement between the user and vendor. Example procedure and values for standard evaluation of 400 nm thick buried oxide are given in the following paragraphs.

8.3.1 *Test Structure* — Buried oxide capacitor having an area equal to or greater than 0.05 cm^2.

8.3.2 *Test Method: Staircase I-V* — Measurement testing can be done for both Type I and Type II defects where Type I defects are silicon pipes traversing the buried oxide, and Type II defects are local regions of thin buried oxide. If Type II defect density is sought, capacitors are subjected to a series of 30 voltage steps of 3.3 volts, with current monitored after each step, using a failure criterion of 1 nA.

8.3.2.1 Arrays of at least 200 capacitors per wafer are tested. Bias polarity of the voltage ramp is chosen so as to accumulate the substrate portion of the capacitor (positive for *n*-silicon, negative for *p*-silicon).

8.3.2.2 Type I defect density is determined using the same test procedure, except that the failure current criterion is 1 µA.

8.3.2.3 Any capacitor displaying the failure current or more for voltages less than 100 volts is considered defective. Defect density of either type is calculated from the yield of good capacitors, (Y = 1 – # failed/# tested), using Poisson statistics;

$$D = -1n (Y)/A,$$

where A is the total area of the capacitors tested.

8.3.2.4 For thin buried oxide (films less than 360 nm), the voltage criteria above need to be adjusted to account for the onset of high field conduction in defect-free capacitors.

8.3.3 *Values*

$$D \text{ (Type I)} < = 0.2 \text{ defects/cm}^2$$

8.3.3.1 No standardized criterion for Type II defects has been established.

8.4 *Buried Oxide Charge* — This parameter can be measured with a buried oxide capacitor (BOX-CAP). The buried oxide thickness and the intended application will affect both the test procedure (such as capacitor area and voltage criterion) and the allowable values of measured parameters. These should be determined by agreement between the user and vendor. Example procedure and values for standard evaluation of 400 nm thick buried oxide are given in the following paragraphs.

8.4.1 *Test Structure* — Buried oxide capacitor having an area of 0.01 cm^2.

8.4.2 *Test Method* — MOS high frequency C-V measurement of a buried oxide capacitor normally yields a flat band voltage less than one volt in magnitude. For a previously untested 400 nm film, this implies an effective fixed charge density of less than 5 Ξ 10^{10} charges/cm^2.

8.4.3 *Values*

$$Qf/q <= 5 \times 10^{10}/cm^2$$

8.5 *Buried Oxide Fast Interfaces State Density* — This parameter can be measured with a buried oxide capacitor (BOX-CAP). The buried oxide thickness and the intended application will affect both the test procedure (such as capacitor area and voltage criterion) and the allowable values of measured parameters. These should be determined by agreement between the user and vendor. Example procedure and values for standard evaluation of 400 nm thick buried oxide are given in the following paragraphs.

8.5.1 *Test Structure* — Buried oxide capacitor having an area of 0.01 cm^2.

8.5.2 *Test Method* — High-Low Frequency MOS C-V. If care is taken in their fabrication to minimize oxide surface damage and contamination during silicon etching, good quality quasi-static MOS C-V curves can be measured on BOX-CAP's. From comparison of high and low frequency C-V curves, midgap interface state density can be determined exactly as for normal MOS capacitors.

8.5.3 *Values*

$$Dit (0) <= 5 \times 10^{10} \text{ states/ /cm}^2\text{-eV}$$

8.6 *Doping Density in the SIMOX Layer*

8.6.1 *Test Structure* — The untreated SIMOX wafer.

Substrate: Buried oxide capacitor, area = 0.01 cm^2

8.6.2 *Test Method* — Spreading Resistance Probing (SRP) offers a way of determining the resistance profile in the Si layer as a function of distance from the top surface. The carrier concentration can be calculated directly from this data.

8.6.2.1 The four point probe method of SIMS can also be used. The four point probe test is liable to punch through and should be considered a destructive test as is SIMS. SIMS will allow for an understanding of compensation effects, if any.

8.6.3 *Values* — The acceptable dopant values are to be determined by agreement between the user and vendor.

8.7 *Doping Density in the Substrate*

8.7.1 *Test Structure* — A buried oxide capacitor (BOX-CAP) area = 0.01 cm^2.

8.7.2 *Test Method* — The electrically active dopant concentration in the substrate immediately beneath the buried oxide can be determined from the standard analysis of high frequency MOS C-V curves measured on BOX-CAPs, dependent on oxide charge and interface properties.

Values — The acceptable dopant values are to be determined by agreement between the user and vendor.

9. Packing and Marking

9.1 Special packing requirements shall be subject to agreement between the user and supplier. Otherwise, all wafers shall be handled, inspected, and packed in such a manner as to avoid chipping, scratches, and contamination and in accordance with the best industry practices to provide ample protection against damage during shipment.

9.2 The wafer supplied under these specifications shall be identified by appropriately labeling the outside of each box or other container, and each subdivision thereof, in which it may reasonably be expected that the wafers will be stored prior to further processing. Identification marks, codes, symbols and content shall be agreed upon between user and supplier.

NOTICE: These guidelines do not purport to address all of the safety issues associated with their use. It is the responsibility of the users of these guidelines to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the guidelines set forth herein for any particular application. The determination of the suitability of these guidelines is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These guidelines are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI M35-0299^E
GUIDE FOR DEVELOPING SPECIFICATIONS FOR SILICON WAFER SURFACE FEATURES DETECTED BY AUTOMATED INSPECTION

This guide was technically approved by the Global Silicon Wafer Committee and is the direct responsibility of the North American Silicon Wafer Committee. Current edition approved by the North American Regional Standards Committee on October 18, 1998. Initially available at www.semi.org February 1999; to be published February 1999.

E This document was editorially modified in March 2000. A change was made to Section 2.1.

1. Purpose

1.1 This guide provides a specification framework for reporting measurements of silicon wafer surface features through the use of scanning (or automated) surface inspection tools, also called SSIS's.

2. Scope

2.1 XLS's are scratches and regions of high roughness. This guide addresses specifications related to localized light scatterers (LLS's) as well as extended light scatterers (XLS's). Examples of LLS's are particles and pits. Examples of XLS's are scratches and regions of high roughness.

2.2 Surface scanners, which have discriminated between XLS's and LLS's for several years, are now discriminating (and selectively reporting) between different types of LLS's (for example: pits and particles).

2.3 Specific numbers limiting feature levels and/or densities are to be agreed upon between suppliers and users. This guide provides a framework for that communication.

2.4 The resulting specifications will be flexible enough to accommodate variations in measurement due to different scanning tools.

3. Discussion

3.1 *Discussion of LLS Measurement Issues*

3.1.1 Because there is considerable variation in the scatter characteristics of different LLS's, they have been historically sized in polystyrene latex sphere (PSL) equivalents. In other words, the signal received from an unknown LLS is equivalent to that which would be obtained from a PSL of known size.

3.1.2 Automated scanning systems typically display a map of LLS location as well as a histogram of (equivalent) PSL size.

3.1.3 The instrumentation industry is working on building scanning tools that will discriminate some LLS's from others based on differences in measured scatter that depend on feature size, shape and material. This raises the question of whether identified LLS's should be sized using PSL equivalents, or if some new (more accurate) standard would be more acceptable. For example, if an LLS signal could be identified as coming from a pit, then it might become appropriate to develop a standard pit wafer. In this case, pits (either manufactured or found naturally) could be measured via atomic force microscope (AFM) and be made available on a calibration wafer to size pits via their measured scatter. Another option, would be to use a model based standard that resides in the SSIS software.

3.2 *Discussion of XLS Measurement Issues*

3.2.1 Identification of scratches is typically done (in part) through software that identifies a string of connected LLS signals. Defects with dimensions such that the length is at least five times the width are defined as scratches. Users and suppliers may agree on scratch aspect ratios different from 5:1. SSIS software often provides a user-settable aspect ratio, as well as a minimum overall length, as criteria for classification of an SSIS defect or group of defects as a scratch. Currently, scratch signals are calibrated in PSL equivalents; however, in the future it may become useful to calibrate scratch signals with a standard obtained from a scratch that has been either manufactured to a known size, or has been measured via AFM.

3.2.2 Haze is specified as parts per million (ppm) of measured scattered optical power relative to the incident optical power on the surface. All of the associated measurement conditions must be given (or implied) with the specified haze value. These conditions include: source incident angle (measured as a polar angle from surface normal), source polarization (S, P, other), source wavelength (or wavelength band), nominal source spot size at the wafer, haze collection angles (given as solid angles with directions). All of these quantities must be part of a haze specification, either by description, or by implication to specific instrumentation (with known or fixed parameters).

3.2.3 Haze is quantified by measuring scattered light power over one or more solid angles and then normalizing by the light power incident on the surface. It is nothing more than the diffuse reflectance of a surface in specified directions for a known source (incident angle, polarization, spot size, wavelength band) and receiver (or detector) configuration (solid angles and locations). Measured haze can be expected to change if the surface is changed, or if any of the measurement parameters change.

3.2.4 Under special conditions, where the source of the haze is known, it may be possible to use a model to predict the haze reading on one instrument from the haze reading on another. For example, if on the basis of product experience and measurements on a few wafers, the surface power spectral density function can be determined, then the haze due to surface roughness can be calculated for an instrument with different parameters. This is the basic idea behind the standard haze wafer (and software) being commercially developed. Haze caused by a large number of small particles and/or film contamination is more difficult to model.

3.2.5 SSIS equipment often reports haze as the arithmetic average of a grid of local haze measurements taken over the FQA. This average can be, and often is, biased by wafer haze distributions that exhibit long, positively skewed tails. SSIS equipment software is being developed that will automatically calculate other haze statistics, such as the median haze value, the standard deviation of the haze distribution and so on.

4. Limitations

4.1 The following measurement considerations impose limitations on the guidelines.

4.1.1 The histograms (currently) calculated in PSL equivalents may be distorted, because a given surface will in general have LLS's of different size, shape and material.

4.1.2 Measurement results do not always compare well between systems, because different tool designs employ different geometries and gather light scattered in different directions. Haze maps may have different levels and localized surface features may have different calculated sizes.

4.1.3 All scanning systems have a minimum (PSL equivalent) LLS size that can be reliably mapped and sized. The limitation is due to a combination of system electrical noise and the detection of non-particle light scatter signals, such as those created by Rayleigh scatter, surface roughness and system optics. Operation near this noise floor limits the utility of this guide for those size LLS's.

4.1.4 Measurements made near the wafer edge often result in large numbers of false counts called edge blast. These counts are caused by small amounts of stray light propagating near the incident beam that scatter from the relatively rough wafer edge back into the detector optics. Under certain combinations of sensitivity and edge exclusion, light scattered from these effects may cause false counts within the FQA.

4.1.5 Types of LLS signals that may be mis-identified as scratches include lines of particles, pits, false counts, stacking faults, slip and spin dry residue.

4.1.6 Closely spaced features may be counted as a single scattering event because the scanning spot size is generally much larger than the feature diameter.

4.1.7 Scratch orientation may affect scanner response. Thus the minimum detectable scratch cross-section may vary with orientation.

5.1 *SEMI Standard*

SEMI M1 — Specifications for Polished Monocrystalline Polished Silicon Wafers

5.2 *ASTM Standards*[1]

F 1620 — Practice for Calibrating a Scanning Surface Inspection System Using Monodisperse Latex Spheres Deposited on Polished or Epitaxial Surfaces.

5.3 *SEMATECH*[2]

*Glossary of Term*s, SEMATECH Technology Transfer Document # 95082941A-TR

6. Terminology

6.1 *edge exclusion* — The width of a narrow band of wafer surface, located just inside the wafer edge, over which the values of the specified parameter do not apply. See the definition for fixed quality area below.

6.2 *extended light scatterer (XLS)* — A feature larger than the spatial resolution of the inspection equipment, on or in a wafer surface, resulting in increased light scattering intensity relative to that of the surrounding wafer, sometimes called an *area defect* (see SEMATECH # 95082941A-TR).

6.3 *fixed quality area (FQA)* — That portion of the area of a wafer surface, defined by a nominal, or specified, edge exclusion, E, over which the specified

1 Available from ASTM, 100 Barr Harbor Drive, West Conshohocken, PA 19428-2959, tel.: 610.832.9585, fax: 610.832.9555, website: www.astm.org

2 Available from SEMATECH, 2706 Montopolis, Austin, TX, tel.: 512.356.3500, fax: 512.779.2826 values of a parameter apply. The FQA lies within and is at all points at least the distance E (the nominal edge exclusion) away from the periphery of a wafer of nominal dimensions (see SEMI M1).

6.4 *haze* — Non-localized light scattering resulting from surface topography (microroughness) or from dense concentrations of surface or near surface imperfections. See *laser light scattering event* and the related Discussion to this definition in SEMI M1.

6.5 *localized light scatterer (LLS)* — An isolated feature, such as a particle or pit, on or in the wafer surface, resulting in increased light scattering intensity relative to that of the surrounding wafer surface; sometimes called *light point defect (LPD)* (see SEMI M1).

6.6 *particle* — A small, discrete piece of foreign material or silicon not connected crystallographically to the wafer (see SEMI M1). Also, see the Discussion related to this definition in SEMI M1.

6.7 *pit* — A depression in a wafer surface that has steeply sloped sides that meet the surface in a distinguishable manner in contrast to the rounded sides of a dimple (see SEMATECH # 95082941A-TR).

6.8 *power spectral density function* — The Fourier decomposition of the surface profile into its component spatial frequencies (see SEMATECH # 95082941A-TR). A statistical function that shows how the mean-square of profile height deviations are distributed among the various surface spatial frequencies inherent in the profile.

NOTE: Similar to the definition found in ASTM Standard F 1811.

6.9 *roughness* — The more narrowly spaced components of surface texture (see SEMI M1.) Also, see the Discussion related to this definition in SEMI M1.

6.10 *scanning surface inspection system (SSIS)* — An instrument for rapid examination of the entire quality area on a wafer to detect the presence of localized light scatterers or haze or both, also called *particle counter* and *laser surface scanner* (see ASTM F 1620).

6.11 *scratch* — A shallow groove or cut below the established plane of the wafer surface, with a length to width ratio greater than 5:1 (see SEMATECH # 95082941A-TR).

7. Specifications

7.1 Specification guidelines are given below for several different LLS's and XLS's.

7.1.1 *Generic LLS* — There shall be no more than N LLS's (particles or pits) of size greater than or equal to D nm in effective PSL diameter on the wafer within an edge exclusion of E mm from the edge.

7.1.1.1 Options: Size ranges and counts may be specified within the FQA.

7.1.2 *Particles* — There shall be no more than N particles of size greater than or equal to D nm in effective PSL diameter on the wafer within an edge exclusion of E mm from the edge. Size ranges and counts may be specified.

7.1.2.1 Options: Size ranges and counts may be specified within the FQA.

7.1.3 *Pits* — There shall be no more than N pits of size greater than or equal to D nm in effective pit diameter on the wafer within an edge exclusion of E mm from the edge. Size ranges and counts may be specified.

7.1.3.1 Options: Size ranges and counts may be specified within the FQA.

7.1.4 *Scratches* — There shall be no more than N scratches of length greater than or equal to L nm on the wafer within an edge exclusion of E mm from the edge.

7.1.4.1 Options: Size ranges and counts may be specified within the FQA.

7.1.4.2 Scratch aspect ratios different than 5:1 and minimum lengths may be used by agreement of user and supplier.

7.1.5 *Generic XLS* — There shall be no generic XLS's of N ppm or greater in an area larger than A mm^2 within an edge exclusion of E mm from the edge.

7.1.6 *Haze (Using Defined Conditions*) — Either local haze or average haze may be specified in the following way. The haze shall not exceed N ppm over the wafer surface when measured under the following conditions:

a. A $\underline{\lambda}$ nm S polarized laser source incident on the sample at $\underline{\theta}$ degrees.

b. Haze measured over a solid angle of $\underline{\Omega}$ sr of circular cross-section centered about the surface normal.

Users and suppliers may agree to use other statistics of the wafer haze distribution in haze specifications.

NOTE: For example: the median wafer haze shall not exceed M ppm; the standard deviation of wafer haze shall not exceed S ppm; the inter-quartile range of wafer haze shall not exceed IQR ppm. Statistics based on the log of the haze distribution may also be used.

7.1.7 *Haze (Using an Instrument Definition)* — Either local haze or average haze may be specified in the following way. The haze shall not exceed N ppm over the wafer surface when measured with a model XXX particle scanner under YYY operating conditions. Users and suppliers may agree to use other statistics of the wafer haze distribution in haze specifications.

NOTE: For example: the median wafer haze shall not exceed M ppm; the standard deviation of wafer haze shall not exceed S ppm; the inter-quartile range of wafer haze shall not exceed IQR ppm. Statistics based on the log of the haze distribution may also be used.

7.2 Specifications may be selected from the following table:

Table 1 Specification Elements Related to Automatic Inspection of Silicon Wafer Surfaces

Parameter	*Specification Elements*	*Specified Measurement Conditions*
1. Generic LLS	___, max number	with equivalent PSL dia ≥ __nm, edge exclusion of __ mm
2. Particles	___, max number	with equivalent PSL dia ≥ __nm edge exclusion of __ mm
3. Pits	___, max number	with equivalent PSL dia ≥ __nm edge exclusion of __ mm
4. Scratches	___, max number	length ≥ __ µm edge exclusion of __ mm
5. Generic XLS	__ ppm, max	with area ≥ __ mm^2 edge exclusion of __ mm
6. Haze (conditions)	__ ppm, max	with __ degree incident angle, at __ nm wavelength, at __ polarization, over __ sr solid collection angle, in __degree polar direction and __ degree azimuthal direction, edge exclusion of __ mm
7. Haze (instrument)	__ ppm, max (or other statistics)	with model XXX SSIS under YYY conditions

SEMI M36-0699
TEST METHOD FOR MEASURING ETCH PIT DENSITY (EPD) IN LOW DISLOCATION DENSITY GALLIUM ARSENIDE WAFERS

This test method was technically approved by the Global Compound Semiconductor Committee and is the direct responsibility of the Japanese Compound Semiconductor Materials Committee. Current edition approved by the Japanese Regional Standards Committee on March 17, 1999. Initially available at www.semi.org April 1999; to be published June 1999.

1 Purpose

1.1 This document provides a method to measure etch pit density (EPD) in low dislocation density GaAs wafers.

2 Scope

2.1 This test method describes a procedure to measure EPD of 50 mm and 76 mm diameter round GaAs wafers with an EPD of less than $5000/cm^2$.

2.2 This test method does not include GaAs wafer preparation, such as wafer slicing, polishing and pit etching. The preparation of GaAs wafer can be found in a Referenced Document.

2.3 This standard does not purport to address all of the safety issues. It is the responsibility of the user of this standard to establish appropriate safety and health practices and to determine the applicability of regulations prior to use of the test method.

3 Referenced Document

3.1 *ASTM Standard*

F 140-92 — Test Method for Crystallographic Perfection of Gallium Arsenide by Molten Potassium Hydroxide (KOH) Etch Technique.

4 Apparatus

4.1 Microscope - Measuring field should be 1 mm^2 or larger.

NOTE: For accurate EPD measurement, accurate area of the measuring field should be measured by a standard scale.

5 Procedure

5.1 The counting positions for 50 mm diameter wafers and for 76 mm diameter wafers are shown in Figure 1 and Figure 2 respectively. The counting points are located in the center of each mesh. In the case of a 50 mm diameter wafer the mesh size is 5 mm. The total number of counting positions is 69 and position 35 is located at the center of the wafer. In the case of 76 mm diameter wafer the mesh size is 10 mm, and the total number of counting position is 37. Position 19 is located at the center of the wafer.

5.2 Count and record the number of etch pits for which the cores are in the measuring field. If the pits are crowded and are difficult to count, increase the magnification. After that count the etch pits and record the results as well as the microscope magnification.

5.3 Repeat Section 5.3 for all other positions, 2 through 69 positions in the case of 50 mm diameter wafers and 2 through 37 positions in the case of 76 mm diameter wafers.

6 Calculations

6.1 The EPD in each measuring field is the number of pits counted divided by the area.

$$EPD = (\text{Number of pits}) / \text{Area}$$

For example, if the size of measuring field is exactly 1 mm × 1 mm, the area is 0.01 cm^2.

7 Report

7.1 There are several forms that are possible for reporting the EPD, for example the average EPD of all the positions or the area less than some specified value or map of EPD for the entire wafer, etc. An appropriate report form should be decided between the supplier and the user.

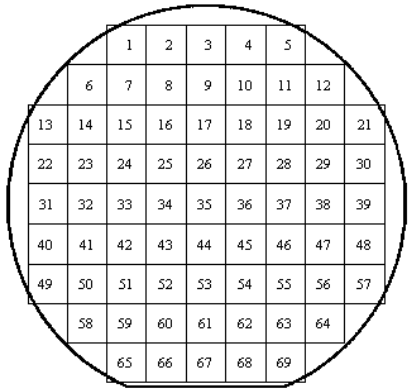

Figure 1

Counting positions for a 50 mm diameter wafer

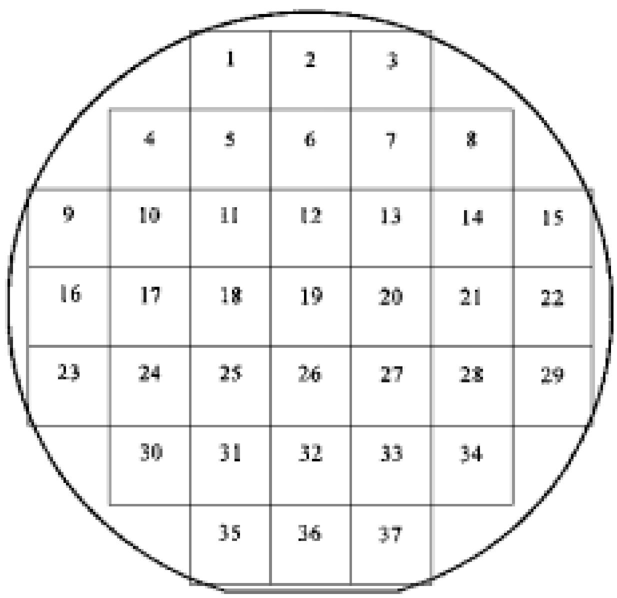

Figure 2

Counting positions for a 76 mm diameter wafer

SEMI M37-0699
TEST METHOD FOR MEASURING ETCH PIT DENSITY (EPD) IN LOW DISLOCATION DENSITY INDIUM PHOSPHIDE WAFERS

This test method was technically approved by the Global Compound Semiconductor Committee and is the direct responsibility of the Japanese Compound Semiconductor Materials Committee. Current edition approved by the Japanese Regional Standards Committee on March 17, 1999. Initially available at www.semi.org April 1999; to be published June 1999.

1 Purpose

1.1 This document provides a method to measure etch pit density (EPD) in low dislocation density InP wafers.

2 Scope

2.1 This test method describes a procedure to measure EPD of 50 mm diameter round InP wafers with an EPD of less than 5000/cm^2.

2.2 This standard does not purport to address all of the safety issues. It is the responsibility of the user of this standard to establish appropriate safety and health practices and to determine the applicability of regulations prior to use of the test method.

3 Referenced Document

3.1 *ASTM Standard*

F 140-92 — Test Method for Crystallographic Perfection of Gallium Arsenide by Molten Potassium Hydroxide (KOH) Etch Technique.

4 Apparatus

4.1 Microscope — Measuring field should be 1 mm^2 or larger.

NOTE: For accurate EPD measurement, accurate area of the measuring field should be measured by a standard scale.

5 Procedure

5.1 Orient the ingot so that the front surface normal direction of the sample is parallel to the <100> within 5°, and then cut a wafer from the ingot.

5.2 Polish the wafer to form a mirror finish. Afterwards, the wafer must be cleaned and dried.

5.3 Mix phosphoric acid (H_3PO_4) and hydrobromic acid (HBr) in a beaker. The ratio of each acid is H_3PO_4: HBr=2:1.

5.4 Immerse the wafer in the mixed acid for 3 minutes at room temperature.

5.5 Rinse the wafer with deionized water and then dry.

5.6 The counting positions are shown in Figure 1. The counting points are located in the center of each mesh. The mesh size is 5 mm and the total number of counting positions is 69. Position 35 is located at the center of the wafer.

5.7 Count and record the number of etch pits for which the cores are in the measuring field. If the pits are crowded and are difficult to count, increase the magnification. After that count the etch pits and record the results as well as the microscope magnification.

5.8 Repeat Section 5.8 for all other positions, 2 through 69.

6 Calculations

6.1 The EPD in each measuring field is the number of pits counted divided by the area.

$$EPD = (\text{Number of pits}) / \text{Area}$$

For example, if the size of measuring field is exactly 1 mm × 1 mm, the area is 0.01 cm^2.

7 Report

7.1 There are several forms that are possible for reporting the EPD, for example the average EPD of all the positions or the area less than some specified value or map of EPD for the entire wafer, etc. An appropriate report form should be decided between the supplier and the user.

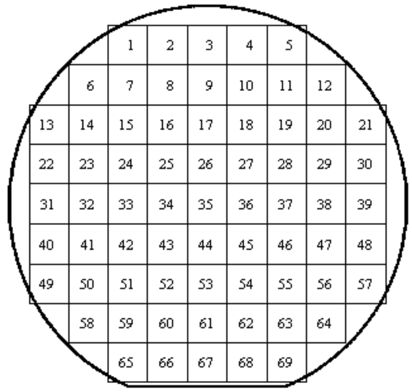

Figure 1

Counting positions for a 50 mm diameter wafer

Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights are entirely their own responsibility.

SEMI M38-1101
SPECIFICATION FOR POLISHED RECLAIMED SILICON WAFERS

This specification was technically approved by the Global Silicon Wafer Committee and is the direct responsibility of the North American Silicon Wafer Committee. Current edition approved by the North American Regional Standards Committee on August 27, 2001. Initially available at www.semi.org September 2001; to be published November 2001. Originally published September 1999; previously published March 2001.

1 Purpose

1.1 This specification covers requirements for reclaimed silicon wafers to be used for testing and process monitoring in semiconductor manufacturing. A reclaimed wafer is a silicon wafer which has been re-conditioned for subsequent utilization.

2 Scope

2.1 A complete purchase specification requires that additional physical properties be defined. These properties are listed, together with test methods suitable for determining their magnitude.

2.2 This specification is directed specifically to silicon wafers with one or both polished surfaces, unpolished, or with epitaxial deposits.

2.3 This specification covers reclaim wafers that are either customer-supplied or third party-sourced. The user should exercise caution when sourcing materials with unknown thermal histories, unknown bulk contamination or unknown deposits, such as gold (Au) films.

2.4 Reclaimed silicon has been divided into four "use" categories: Mechanical, Furnace, Particle, and Lithography. The intent is that a prospective purchaser or reclaimed silicon needs to know which application matches his requirements and which wafer attributes are important for that application.

2.5 For applications placing higher demands on silicon wafers such as particle counting, measuring pattern resolution in a photolithography process, or surface ion contamination monitoring, the user may want to reference SEMI M1, M8, or M24.

2.6 For referee purposes, U.S. customary units shall be used for wafers of 2- and 3-inch nominal diameter and SI (System International), commonly called metric units, for 100 mm and larger diameter wafers.

2.7 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

4 Terminology

4.1 Definitions of terms related to silicon wafer technology are given in ASTM Terminology F 1241.

4.2 Definitions for some additional terms are given in SEMI M1.

4.3 The following definitions apply in the context of this specification:

4.3.1 *furnace wafer* — a silicon wafer which can be used for monitoring thermal processes or as an implant monitor and is usually only used in a cleanroom.

4.3.2 *hand scribe mark* — any marking, usually on the back surface of a wafer, scratched manually into the silicon surface, as with a diamond tipped scribe, for purposes of wafer identification.

4.3.3 *lithography wafer* — a silicon wafer used specifically for testing lithography equipment wherein surface flatness is key to process monitoring. This wafer is usually only used in a cleanroom environment.

4.3.4 *mechanical wafer* — a silicon wafer suitable for equipment or process testing which is usually only used outside of a cleanroom environment.

4.3.5 *particle wafer* — a silicon wafer which can be used for monitoring area or process cleanliness and is only used in a cleanroom environment.

4.3.6 *reclaimed wafer* — a silicon wafer which has been reconditioned for subsequent utilization.

4.3.7 *test wafer* — a silicon wafer suitable for process monitoring in semiconductor manufacturing. Also called *monitor wafer*.

5 Ordering Information

5.1 Purchase orders for reclaimed silicon wafers furnished to this specification shall minimally include the following items:

5.1.1 Customer-supplied or third-party sourced, and

5.1.2 Nominal diameter, conductivity type, resistivity, and surface orientation.

5.2 Following are the optional criteria to include in a prospective purchase order:

5.2.1 Lot acceptance criteria,

5.2.2 Certification,

5.2.3 Packing and Marking,

5.2.4 Minimum removal requirements (if any), and

5.2.5 Lot traceability and lot integrity maintenance requirements.

5.3 This specification is divided into four application categories or tables: Mechanical, Furnace, Particle, and Lithography. For ordering purposes, attributes applicable to each use are listed in the appropriate table.

6 Dimensions and Permissible Variations

6.1 The material shall conform to the parameters as specified in Tables 1 through 9.

6.2 The material shall conform to the crystallographic orientation details as listed in the tables.

7 Materials and Manufacture

7.1 The material shall consist of silicon wafers which are capable of being reconditioned for use.

8 Electrical Requirements

8.1 The material shall conform to the details specified in the purchase order or contract, as follows:

8.1.1 Conductivity type

8.1.2 Resistivity

9 Sampling

9.1 Unless otherwise specified, ASTM Practice E 122 shall be used. When so specified, appropriate sample sizes shall be selected from each lot in accordance with ANSI/ASQC Z 1.4. Each quality characteristic shall be assigned an acceptable quality level (AQL) and lot total percent defective (LTPD) value in accordance with ANSI/ASQC Z 1.4 definitions for critical, major, and minor classifications. If desired and so specified in the contract or order, each of these classifications may alternatively be assigned cumulative AQL and LTPD values. Inspection levels shall be agreed upon between the supplier and the purchaser.

10 Test Methods

NOTE 2: Silicon wafers are extremely fragile. While the mechanical dimensions of a wafer can be measured by use of tools such as micrometer calipers and other conventional techniques, the wafer may be damaged physically in ways that are not immediately evident. Special care must therefore be used in the selection and execution of measurement methods.

NOTE 3: The kind of dopant used is difficult to ascertain in finished wafers. Verification test procedures for certification of these characteristics shall be agreed upon between the supplier and the purchaser.

10.1 *Diameter* — Determine in accordance with ASTM Test Method F 613.

10.2 *Thickness, Center Point* — Determine in accordance with ASTM Test Method F 533 or DIN 50441/1, or JIS H 0611.

10.3 *Flat Length* — Determine in accordance with ASTM Test Method F 671.

10.4 *Flat Orientation* — Determine in accordance with ASTM Test Methods F 847.

10.5 *Surface Orientation* — Determine in accordance with ASTM Test Methods F 26 or DIN 50433.

10.6 *Surface Defects and Contamination* — Determine in accordance with ASTM Practice F 523. The following conditions shall be used (unless otherwise specified in the purchase or contract):

a. Background light intensity:

8 ± 2 fc (86 ± 22 lux)

b. Angle α (alpha): 45° ± 10°

c. Angle β (beta): 90° ± 10°

10.6.1 See Section 10 for surface defect criteria and Table 2 for allowable levels of defects. In the event the wafers fail to meet these criteria, they shall be conditioned according to ASTM Practice F 612 or other cleaning procedure as agreed upon between supplier and user and retested.

NOTE 4: ASTM Practices F 154 is a useful guide for defining a variety of surface features found on silicon surfaces and for establishing commonly understood terms for describing them. It also gives detailed procedures for illumination and microscopical examination of surfaces.

10.7 *Conductivity Type* — Determine in accordance with ASTM Test Methods F 42 or DIN 50432.

10.8 *Resistivity* — Determine by methods agreed upon between the supplier and the purchaser.

NOTE 5: Resistivity of wafers is most appropriately determined for referee purposes by ASTM Method F 84 or DIN 50431. Under some circumstances these tests may be considered destructive, and an alternative means may be required. A widely used nondestructive test is ASTM Test Methods F 673, having a range from 0.0001 to 200 Ω • cm.

10.9 *Radial Resistivity Variation* — Determine in accordance with ASTM Test Methods F 81 or DIN 50435.

10.10 *Crystal Perfection* — Determine in accordance with ASTM Test Method F 47 or DIN 50434 (to determine grain boundaries, twinning, slip, dislocations, and lineage).

10.11 *Edge Profile* — Determine in accordance with ASTM Test Methods F 928 or DIN 50441/2.

11 Surface Defect Criteria

11.1 *Minimal Conditions or Dimensions* — The minimal conditions or dimensions for defects stated below shall be used for determining wafer acceptability. Anomalies smaller than these limits shall not be considered defects.

11.2 *area contamination* — any foreign matter on the surface in localized areas which is revealed under the inspection lighting conditions as discolored, mottled, or cloudy appearance resulting from smudges, stains, water spots, etc.

11.3 *crack* — any anomaly conforming to the definition and greater than 0.25 mm (0.010 inch) in total length.

11.4 *crow's foot* — any anomaly conforming to the definition and greater than 0.25 mm (0.010 inch) in total length.

11.5 *dimple* — any smooth surface depression greater than 3 mm in diameter.

11.6 *edge chip and indent* — any edge anomaly including saw exit marks conforming to the definition and greater than 0.25 mm (0.010 inch) in radial depth and peripheral length.

11.7 *hand scribe mark* — any mark such as that caused by a diamond scribe that is visible under diffuse illumination.

11.8 *haze* — haze is indicated when the image of a narrow beam tungsten lamp filament is detectable on the polished wafer surface. (Under some conditions contamination may appear as haze.)

11.9 *orange peel* — any roughened surface conforming to the definition that is observable under diffuse illumination.

11.10 *particulate contamination* — distinct particles resting on the surface which are revealed under collimated light as bright points.

11.11 *pit* — any individually distinguishable non-removable surface anomaly conforming to the definition and visible when viewed under high intensity illumination.

11.12 *saw marks* — any surface irregularities conforming to the definition that is observable under diffuse illumination.

11.13 *scratch* — any anomaly conforming to the definition and having a length-to-width ratio greater than 5:1.

11.14 *slip* — any pattern of short ridges aligned along <110> directions and visible under diffuse illumination.

11.15 *striations* — any helical features conforming to the definition and visible under diffuse illumination.

12 Certification

12.1 Upon request of the purchaser in the contract or order, a manufacturer's or supplier's certification that the material was manufactured and tested in accordance with this specification, together with a report of the test results, shall be furnished at the time of shipment.

12.2 In the interest of controlling inspection costs, the supplier and the purchaser may agree that the material shall be certified as "capable of meeting" certain requirements. In this context, "capable of meeting" shall signify that the supplier is not required to perform the appropriate tests in Section 9. However, if the purchaser performs the test and the material fails to meet the requirement, the material may be subject to rejection.

13 Packing and Marking

13.1 Special packing requirements shall be subject to agreement between the supplier and the purchaser. Otherwise all wafers shall be handled, inspected, and packed in such a manner as to avoid chipping, scratches, and contamination, and in accordance with the best industry practices, to provide ample protection against damage during shipment.

13.2 The wafers supplied under this specification shall be identified by appropriately labeling the outside of each box or other container and each subdivision thereof in which it may reasonably be expected that the wafers will be stored prior to further processing.

14 Tables

14.1 Please note the following terminology for the tables:

unspecified — an attribute which is not specified,

user specified — an attribute which may be specified, and

as-supplied — an attribute which is pre-established in the as-delivered wafer for reclaim.

NOTE 3: To be negotiated between user/supplier.
NOTE 4: The nµmber of Localized Light Scatterers (LLS) per wafer is to be determined by user/supplier agreement; the LLS size in PSL equivalents is specified as ≥ 0.16 µm with a goal of decreasing to 0.12 µm. A recommended value is ≤ 200 @ ≥ 0.16 µm (interpreted as particles + COP's) or ≤ 50 @ ≥ 0.16 µm (for particles only – which may be distinguished from COP's by metrology with user/supplier agreement on the tool and methodology.

NOTICE: SEMI makes no warranties or representations as to the suitability of the standard set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials or equipment mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI M39-0999
TEST METHOD FOR MEASURING RESISTIVITY AND HALL COEFFICIENT AND DETERMINING HALL MOBILITY IN SEMI-INSULATING GaAs SINGLE CRYSTALS

This test method was technically approved by the Global Compound Semiconductor Committee and is the direct responsibility of the Japanese Compound Semiconductor Committee. Current edition approved by the Japanese Regional Standards Committee on June 1, 1999. Initially available at www.semi.org August 1999; to be published September 1999.

1 Purpose

1.1 The purpose of this document is to specify a method to measure resistivity and determine Hall mobility of semi-insulating GaAs single crystals by the Van der Pauw method. Especially, this document specifies a simple and practical method for commercial semi-insulating GaAs single crystals.

2 Scope

2.1 This test method covers a procedure for measuring the resistivity and determining Hall mobility of semi-insulating GaAs single crystals by the van der Pauw method. This method requires a singly connected test specimen without any isolated holes, of homogeneous thickness and with a square shape. In this method, contacts must be sufficiently small and located at the corners of the specimen.

2.2 This standard may involve hazardous materials, operation, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Referenced Standards

3.1 *ASTM Standards*

F 76-73 — Standard Method for Measuring Hall Mobility and Hall Coefficient in Extrinsic Semiconductor Single Crystals

F 76-86 — Standard Test Methods for Measuring Resistivity and Hall Coefficient and Determining Hall Mobility in Single-Crystal Semiconductors

F 43-93 — Standard Test Methods for Resistivity of Semiconductor Materials

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

4 Terminology

NOTE 2: Many of the terms associated with this test method can be found in ASTM Definitions F 76-86.

hall mobility — the ratio of the magnitude of the Hall coefficient to the resistivity; it is readily interpreted only in a system with carriers of one charge type.

resistivity — the ratio of the potential gradient parallel to the current in the material to the current density. For the purpose of this method, the resistivity shall always be determined for the case of zero magnetic flux.

5 Summary of Test Method

5.1 In this method, the thickness of a specimen cut from a semi-insulating GaAs single crystal is measured.

5.2 Ohmic contacts are formed on the specimen.

5.3 The temperature near the specimen is measured.

5.4 Hall-effect measurement is performed and data are taken.

5.5 From the measured data, the resistivity and Hall mobility are calculated and corrected for temperature.

6 Interferences

6.1 Light could cause an error due to photo-conductivity, so the specimen must be placed in a dark environment.

6.2 Temperature fluctuation gives significant error. Specimen itself could be at higher temperature than the environment if one does not take sufficient time after soldering the contacts.

6.3 The current-voltage conditions must be ohmic.

6.4 The damaged layer due to the sawing must be removed by etching the specimen, for example by using mixture of sulfuric acid (H_2SO_4), hydrogen peroxide (H_2O_2) and water (H_2SO_4:H_2O_2:H_2O = 3:1:1).

7 Apparatus

7.1 *Measurement of Specimen Thickness* — Dial gauge, micrometer, or electronic thickness gauge capable of measuring the specimen thickness within ± 1% must be used.

7.2 *Magnet* — A calibrated magnet capable of providing a magnetic flux density uniform within ± 1% over the area in which the test specimen is to be located. Flux densities must be between 3,000–10,000 gauss (0.3T–1.0T).

7.3 *Instrumentation*

7.3.1 *Current Source* — Capable of maintaining current through the specimen constant to ± 1% during the measurement. The current source is accurate to ± 1% on all ranges used in the measurement.

7.3.2 *Electrometer or Voltmeter* — With which voltage measurements can be made to an accuracy of ± 1%. The input resistance of the electrometer (or voltmeter) must be greater than 1E13 Ω. In addition to the Electrometer, the input resistance greater than 1E13 Ω must be kept in the Hall measurement system.

7.4 *Specimen Holder*

7.4.1 *Container* — Used to hold the specimen, to isolate it from surroundings and shield it from light.

7.4.2 *Thermometer* — Located in close proximity to the test specimen and associated instruments for monitoring temperature to an accuracy of ± 0.1°C during the measurement. This may include, for example, a thermocouple.

8 Reagents and Materials

8.1 *Purity of Reagents* — All chemicals for which such specifications exist shall conform to SEMI C1.

8.2 *Purity of Water* — When water is used, it is either distilled water or deionized water having a resistivity greater than 2MΩcm at 25°C as determined by the Non-Referee Test of Test Methods D 1125.

9 Test Specimen Preparation

9.1 Regardless of the specimen preparation process used, high-purity reagents and water are required.

9.2 *Material* — The test specimen is prepared from a sliced wafer of a GaAs single crystal.

9.3 *Specimen Cutting*

9.3.1 Cut wafers which have a thickness ranging from 0.3 to 1.0 mm from a GaAs single crystal.

9.3.2 Clean and etch them, for example by a sulfuric acid/peroxide solution (H_2SO_4:H_2O_2:H_2O = 3:1:1), in order to remove surface damage and to obtain smoother surfaces. Polishing can be used instead of etching.

9.3.3 Cleave or dice the test specimen into a square shape with each side length from 3 mm to 10 mm. The thickness variation over the specimen should be in ± 1%.

9.4 *Contact Formation*

9.4.1 Ohmic contact materials can be In, AuGe/Au or AuGe/Ni.

9.4.2 Place the contacts on four corners of the specimen.

9.4.3 Maintain the contact dimensions as small as possible relative to the peripheral length of the specimen. Recommended dimension of the contact is not greater than 1/10 of the side length of the specimen.

10 Measurement Procedure

10.1 *Thickness Measurement* — Measure the specimen thickness, t[cm] with a precision of ± 1%.

10.2 *Contact Evaluation* — Verify that all combinations of contact pairs in both polarities have linear current-voltage characteristics, without noticeable curvature, about the actual value of current to be used and at the measurement temperature.

10.3 *Specimen Placement* — Place the clean and contacted specimen in its container. If a permanent magnet is used to provide the magnetic flux, keep the magnet and the specimen separate during the measurement of resistivity. If an electromagnet is used, be certain that the residual flux density is small enough not to affect the resistivity measurement.

10.4 *Resistivity Measurement (see Figure 1)* — Measure the temperature, T_1, of the specimen. Set the current magnitude, I, to the desired value in a linear region. Measure the voltages V_1 at I_1 and V_2 at I_2. T_1 shall be 25 ± 5°C and the fluctuation of T_1 shall be maintained to ± 1°C during the resistivity measurement.

10.5 *Hall Mobility Measurement (see Figure 2)*

10.5.1 Position the specimen between the magnet-pole pieces so that the magnetic flux is perpendicular to the two flat faces of the specimen.

10.5.2 Measure the temperature, T_2, of the specimen. Set the current magnitude, I, to the desired value. Measure the voltage V_3 with the magnetic flux and V_4 without the magnetic flux.

10.5.3 T_2 shall be 25 ± 5°C and the fluctuation of T_2 shall be maintained to ± 1°C during Hall mobility measurement.

11 Calculations

11.1 *Resistivity*

$\rho = (\pi \times t/2 \ln 2) \times (R_1 + R_2) \times f(R_1/R_2)$ [Ω·cm]

where:

t is the specimen thickness,

R_1 and R_2 are the equivalent resistances

for two opposite sides as follows:

$R_1 = V_1/I_1$

$R_2 = V_2/I_2$

$f(R_1/R_2)$ is the correction factor for specimen shape.

In the case of $R_1/R_2 < 10$,

$f(R_1/R_2) = 1 - 0.34657A - 0.09236A^2$

where: $A = [(R_1/R_2 - 1)/(R_1/R_2 + 1)]^2$

11.2 *Hall Mobility*

$\mu = (t/B) \times R_3/\rho$ [cm^2 / V·s]

where:

B is the magnetic flux density,

$R_3 = V_3 - V_4$ / I

where:

V_3 is the voltage when the current is I under magnetic flux

V_4 is the voltage when the current is I without magnetic flux.

11.3 *Temperature Conversion*

11.3.1 *Resistivity*

$\rho_T = \rho_{T1} \cdot \exp[-Ea/k \cdot (1/T_1 - 1/T)]$

where:

Ea is the activation energy (= 0.75eV)

k is the Boltzman constant (= 8.61E – 5 eV/K)

ρ_T is the resistivity at T(K)

11.3.2 *Hall Mobility*

$\mu_T = \mu_{T2}(T/T_2)^{-3/2}$

where: μ_T is the Hall mobility at T(K)

12 Report

12.1 The following information shall be included in the report for referee and research measurement:

12.1.1 Identification of test specimen,

12.1.2 Test temperature,

12.1.3 Specimen shape used, orientation, and corresponding dimensions,

12.1.4 Magnitude of magnetic-flux density, and

12.1.5 Calculated resistivity and Hall mobility.

SEMI M40-0200
GUIDE FOR MEASUREMENT OF SURFACE ROUGHNESS OF PLANAR SURFACES ON SILICON WAFER

This guide was technically approved by the Global Silicon Wafer Committee and is the direct responsibility of the North American Silicon Wafer Committee. Current edition approved by the North American Regional Standards Committee on December 15, 1999. Initially available at www.semi.org February 2000; to be published February 2000.

1 Purpose

1.1 This guide provides procedures for specifying the measurements to be used in characterizing and reporting roughness of the planar surfaces of silicon wafers. It may also be applicable to other types of planar wafer materials.

1.2 This guide provides nomenclature and procedures for roughness determination that employ three key methodologies:

1.2.1 Standardized scan site patterns,

1.2.2 Roughness abbreviations, and

1.2.3 Reference test methodologies with respect to identifying specific roughness measurements.

2 Scope

2.1 This guide incorporates the following methodologies:

2.1.1 Standardized scan patterns for both local and full-area surface characterization,

2.1.2 A set of roughness abbreviations that describe measurement conditions in a short-hand code, and

2.1.3 Reference test methodologies for three generic types of roughness measuring instruments. These general categories may include, but are not limited to:

- Profilometers — AFM and other scanning probe microscopes; optical profilometers; high-resolution mechanical stylus systems,
- Interferometers — interference microscopes, and
- Scatterometers — Total integrating scatterometers (TIS), angle-resolved light scatterometers (ARLS), scanning surface inspection systems (SSIS).

2.2 Procedures to obtain a representative value of roughness for a surface are specified.

2.3 Roughness nomenclature is intended to remove ambiguities with respect to identifying the roughness measurements used and the results achieved.

2.4 This guide does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this guide to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This guide does not apply to measurements in the edge region of wafers.

3.2 This guide does not apply to spatial wavelengths ≤ 10 nm.

3.3 This guide is not intended to define specific roughness parameters; these can be found in other documents.

3.4 The bandwidth of the measurement tool and the bandwidth used can severely influence the result of roughness measurements.

3.4.1 Differences in either long or short bandwidths used between two instruments can produce significantly different results.

3.4.2 The codes listed in Table 1 of this guide do not identify instrument transfer functions.

3.5 The presence of films may affect light scattering measurements.

4 Discussion

4.1 Roughness of silicon wafer surfaces is becoming frequently specified for bare silicon wafers (cf. the SIA International Technology Roadmap for Semiconductors). These specifications refer to the roughness of both the final polished front and the back surfaces of a wafer. Various techniques are currently used to measure the surface roughness of silicon wafers. These techniques include AFM scanning probes, mechanical and optical profiling, interferometric microscopes, and light (electromagnetic radiation) scattering. Mechanical profiling techniques are widely used in other industries and are well standardized. Profiling techniques are generally limited to line scans and therefore provide information of only a very small part of a surface. Interferometric techniques for roughness measurements are similarly limited, whereas light scattering techniques can scan the entire wafer surface.

4.2 Historically a variety of roughness parameters for profiling techniques have evolved and have been standardized, including rms roughness (R_q) and average roughness (R_a). Profiling instruments measure the surface topography and derive roughness statistics, such as R_q, from a series of height data. Light scattering techniques measure R_q from the angular dependence of scattering; some light scattering systems derive other parameters through interpretation and estimation.

4.3 A roughness value representative of an entire wafer surface, or a large portion of the surface, cannot be based on data obtained at a single point. Yet, specifications often describe a single value for a wafer. Therefore, this guideline suggests and defines standardized patterns of scan sites that can be described and used unambiguously. A model describing the relationship between several types of roughness variation, scan patterns, and reported results is included in the attached Related Information to assist users in specifying and interpreting these variables.

4.4 A common feature of all roughness measurements is their dependence on the bandwidth and transfer function of the tool used. In addition, high or low spatial frequency software filters are common and affect reported results. Widely different numbers can be reported for the same surface by two measurement instruments. This guideline includes suggestions on specifying and reporting the instrument bandwidth and transfer function.

International Technology Roadmap for Semiconductors[6]

Optical Scattering in the Optics, Semiconductor, and Computer Disk Industries, Second Edition 1995, J C Stover, Editor[7]

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

6 Terminology

6.1 *autocorrelation function* — the Fourier transform of the Power Spectral Density function. It expresses the similarity between a surface profile and the same profile that is slipped, or moved laterally, with respect to itself.

6.2 *autocorrelation length* — the lateral slip required to reduce the Autocorrelation function to a value equal to e-1 times its zero slip value. Sometimes 10% or even 0 value definitions are used instead of e-1.

6.3 *average roughness* (R_a) — the average of the surface profile height deviations Z(x) from the mean line taken within the evaluation length (ASME B46.1).

6.4 *bi-directional reflectance distribution function, BRDF* — a description of the distribution of light scattered by a surface, it is the differential radiance normalized by the differential irradiance, and is approximated by the scattered power per unit projected solid angle divided by the incident power (Stover).

6.5 *fixed quality area (FQA)* — the central area of a wafer surface, defined by a nominal edge exclusion, *X*, over which the specified values of a parameter apply (SEMI M1). See also the discussion immediately following this definition in SEMI M1.

6.6 *haze* — non-localized light scattering resulting from surface topography (microroughness) or from dense concentrations of surface or near-surface imperfections (SEMI M1).

DISCUSSION — Haze due to the existence of a collection of imperfections is a mass effect; individual imperfections of the type which result in haze cannot be readily distinguished by the eye or other optical detection systems without magnification. In a particle counter (SSIS), haze results in a background signal and laser light-scattering events together comprise the signal due to light-scattering from a wafer surface. (SEMI M1). It is the total scattered optical flux collected by an optical system normalized by the incident flux.

NOTE 2: Different SSIS instrument types may give significantly different haze values on a given sample.

6.7 *illumination source incidence angle* — the angle of the incoming beam, measured from surface normal.

6.8 *kurtosis (Rku)* — a measure of the sharpness of the histogram of surface profile height deviations *Z(x)* from the mean line within the evaluation length. A complete random surface will have a Gaussian histogram and *Rku* = 3 (ASME B46.1).

6.9 *laser light-scattering event* — a signal pulse that exceeds a preset threshold, generated by the interaction of a laser beam with a discrete scatterer at a wafer surface as sensed by a detector; see also *haze* (SEMI M1). See also the discussion that follows this definition in SEMI M1.

6.10 *lay* – the predominant direction of the surface pattern, ordinarily determined by the production method used (ASME B46.1).

6.11 *microroughness* — surface roughness components with spacing between irregularities (spatial wavelength) less than about 100 µm (SEMI M1).

6.12 *Nyquist Criterion* — the shortest spatial wavelength detected. It is twice the sample spacing.

6.13 *one-dimensional grating equation* — in its most common form, it is an expression that gives the positions of diffracted orders from a one-dimensional sinusoidal grating (Stover).

6.14 *peak to valley* (R_t) — the highest to lowest value of the surface profile height deviations *Z(x)* from the mean line taken within the evaluation Length *L* (ASME B46.1).

6.15 *power spectral density (PSD) function* — a surface characterization function that is proportional to the square of the modulus of the Fourier transform of the surface and may be considered as a roughness power per unit of spatial frequency (ASTM F 1811).

6.16 *Rayleigh Criterion (of resolving power)* — a condition for distinguishing a pair of diffraction patterns whereby the maximum of one pattern overlaps with the minimum of the other.

DISCUSSION — When a lens is free from aberrations, the images of point objects appear as diffraction patterns. When the principle maximum of one pattern strikes the first minimum of another, the images are described as being resolved. With respect to circular optics, this criterion applies when the distance between resolvable point objects, viewed from the objective lens of the instrument, is

6 Semiconductor Industry Association (SIA), 181 Metro Drive, Suite 450, San Jose, CA

7 SPIE, P.O. Box 10, Bellingham, WA 98227-0010

$$\frac{0.61\lambda}{NA}$$

where NA is the numerical aperture of the objective lens and λ is the illumination wavelength.[8]

6.17 *rms area microroughness* (R_qA) — the root mean square of the topographic deviations of a surface $Z(x,y)$ from the mean surface taken within the evaluation Area ($=L_xL_y$) (SEMI M1). See also the extended discussion that follows this definition in SEMI M1.

6.18 *rms microroughness* (R_q) — the root mean square of the surface profile height deviations $Z(x)$ from the mean line taken within the evaluation Length L (SEMI M1). See also the extended discussion that follows this definition in SEMI M1.

6.19 *rms slope (mq)* — the root-mean-square value of the rate of change of profile departures within the evaluation length (Adapted from ISO 4271/1).

6.20 *roughness* — the more narrowly spaced components of surface texture (SEMI M1). Compare with *waviness*.

6.21 *skewness (Rsk)* — a measure of the asymmetry of the surface topographic deviations of a surface $Z(x,y)$ about the mean line. A perfect random surface will have $Rsk = 0$ (*ASME B46.1*).

6.22 *spatial bandwidth* — the range of wavelengths in which a given instrument operates (Stover).

6.23 *spatial frequency* — spatial frequency ($F_{spatial}$) is the inverse of spatial wavelength ($\lambda_{spatial}$).

6.24 *spatial wavelength* — the spacing between adjacent peaks of a purely sinusoidal profile (*ASME B46.1*).

6.25 *ten point roughness height* (R_z) — the average value of the absolute values of the heights of the five highest profile peaks and the depths of the five lowest profile valleys from the mean line taken within the evaluation length. (Adapted from ISO 4281/1.)

6.26 *transfer function* — the response of an instrument over all measured spatial wavelengths.

DISCUSSION — A perfect instrument would have a 100% response over all spatial wavelengths. Every measuring instrument will have some deviation from a perfect response especially at the low spatial frequency limit (the traversing length) and at the high spatial frequency limit. The power spectrum can be used to examine this limit near the high spatial frequency response. Contact the instrument supplier for this information.

6.27 *traversing length* — the maximum distance sampled in a given direction. The maximum measurable spatial wavelength is always less then the traversing length.

6.28 *wavelength scaling* — a surface is said to wavelength scale if the scatter measurements at one wavelength may be used to predict scatter measurements at another wavelength (Stover).

6.29 *waviness* — the more widely spaced (spatial wavelength) components of surface texture (SEMI M1). Compare with *roughness*.

7 Instruments and Capabilities

7.1 *Profilometers*

7.1.1 The high spatial frequency limit of AFM, mechanical and optical profilers can be approximated by the radius of the mechanical tip or by the diameter and intensity profile of the laser spot, respectively. Their response functions are complicated, and in some cases are a combined effect of the probe and the measured surface. The high spatial frequency limit of such tools has to be set or selected reasonably removed from that limit in order to achieve reasonable, comparable, and repeatable measurements.

7.2 *Interference Microscope*

7.2.1 The high spatial frequency limit of these instruments is defined by the focusing optics or in some cases by the pixel spacing of the detector array. The high spatial frequency limit of such tools has to be set or selected reasonably removed from that limit in order to achieve reasonable, comparable, and repeatable measurements.

7.3 *Scattering Instruments*

7.3.1 A straightforward relation between scattered light intensity and roughness exists only for sufficiently smooth surfaces. The Rayleigh smooth-surface criterion, given below, is frequently used for estimating the smooth-surface limit (Stover).

$$\frac{1}{2}\left(\frac{4\pi a\cos\theta_i}{\lambda}\right)^2 << 1 \quad (1)$$

$$m << 1 \quad (2)$$

where: m = profile slope,

λ = wavelength of incident light,

a = amplitude of sample profile (half of the peak-to-valley height), and

8 Optics, Eugene Hecht, et al; 3rd edition (August 1997); Addison-Wesley Publishing Co; ISBN: 0201838877

θ_i = incidence angle of light.

7.3.2 Corresponding amplitude examples assuming a limit of 0.1 result in

$a \leq 23$ nm for $\lambda = 633$ nm, $\theta_i = 0°$ and

$a \leq 51$ nm for $\lambda = 488$ nm, $\theta_i = 70°$

7.3.3 The equivalent rms-roughness values for a sinusoidal profile and for a limit of 0.1 are

$R_q \leq 16$ nm for $\lambda = 633$ nm, $\theta_i = 0°$ and

$R_q \leq 36$ nm for $\lambda = 488$ nm, $\theta_i = 70°$

7.3.4 Light scattering tools can be applied to rougher surfaces than those surfaces identified in equations 1 and 2, but then other mathematical approaches as compared to PSD curves have to be applied to calculate roughness or slope values. Also, the slope of the PSD curve can be important in certain situations (Stover).

7.3.5 There is a basic high spatial frequency (short spatial wavelength) limit for light scattering tools which cannot be exceeded. This limit is:

a) twice the inverse wavelength, $\frac{2}{\lambda}$, of the light used in case of grazing incidence ($\theta_i = 90°$), and

b) one inverse wavelength, $\frac{1}{\lambda}$, in the case of normal incidence ($\theta_i = 0°$).

These conditions follow directly from the one-dimensional grating equation

$$f_x = \frac{\sin\theta_s \cos\phi_s - \cos\theta_i}{\lambda}$$

where: θ_s = scattering angle in the incident plane, and

ϕ_s = scattering angle out of the plane-of-incidence.

NOTE 3: f_x becomes -1 when the light is scattered back in the direction of the incoming light in the incident plane (ϕ_s = 180°).

7.4 *Total Integrating Scatterometers (TIS)*

7.4.1 These instruments most often use an incidence angle close to zero. The low and high frequency limits of the accessible spatial bandwidth are defined by the design of the optical system. An appropriately designed system may be able to access a spatial bandwidth from about 0.8 µm to about 40 µm. These systems may also be designed so that the scattered signal can be broken into low spatial frequency (near specular) and high spatial frequency (large scatter angle) bands.

7.5 *Angle-resolved Light Scatterometers (ARLS)*

7.5.1 The high spatial frequency limit of this technique is defined by incident and scattering angles and the illumination wavelength used.

7.5.2 The low spatial frequency limit is given by

- the above equations (for incidence angle),
- the diameter of the incident illumination spot at the wafer surface,
- the solid collection angle of the optical system, and
- the smallest angular distance allowed by the instrument between specular reflected light and the detector.

7.5.3 The roughness may be measured by using a fixed incidence angle and by recording the intensity of scattered light at various scattering angles in the plane of incidence. The two-dimensional PSD curve of the surface can then be calculated from the angular spectrum of the scattered light (BRDF). R_q as well as mq may be calculated from a one-dimensional or isotropic PSD curve for a given spatial bandwidth as long as the above mentioned limits are accommodated.

7.5.4 Such tools may be able to access a spatial bandwidth range of about one-half the wavelength of the illuminating light up to several hundred µm.

7.6 *Scanning Surface Inspection Systems (SSIS)*

7.6.1 SSIS measurements are integrated scatter measurements similar to those made by TIS systems, in that they gather light over large solid angles; however, there are some significant differences. In general, most SSIS avoid light collection within five to ten degrees of the specular beam, because in this region the scatter tends to be dominated by surface roughness scatter (which becomes background noise) competing with the signal from laser light scattering events. The early (older) scanners generally had one detector measuring light from a very large solid angle collector. Later systems tend to use several smaller collection angles, each with their own detector. Whatever the arrangement, each collection angle can be defined in terms of its spatial frequency band pass region, and each detector will have some background haze component (or threshold) that is caused by surface roughness. Thus, in the absence of laser light scattering events, measured haze may be converted to an rms roughness for the defined spatial frequencies. This conversion assumes that the surface meets the necessary (smooth, clean, front surface reflective) conditions required for roughness calculations, and that other noise sources, such as background electronic noise and Rayleigh air scatter, are not issues.

8 Roughness Measurements

8.1 *Parameters*

8.1.1 R_q and R_a are generally used for silicon wafer surfaces. Other roughness measurement parameters may also prove useful. This guideline does not suggest which parameters to use, rather it suggests how to incorporate any parameter into a standardized measurement specification.

8.2 *Measurement Sites*

8.2.1 Roughness can vary considerably across a wafer surface. It may also have a preferential direction or anisotropy, often called "lay" (ASME B46.1). Many measurement techniques are limited to a very small measurement area and to one or two scan directions. Therefore specific measurement patterns must be defined to obtain representative and reproducible results. These patterns should correspond to effects observed on wafers in different manufacturing steps. These processing steps can generate features on a wafer surface with rotational symmetries ranging from mirror to infinite. The wafer slicing process may produce low symmetry, while single-wafer polishing can produce high symmetry.

8.2.2 In cases where only a small number of spots is measured, the spot pattern and the scan orientation have to be identified. See Figure 1 for some patterns and orientations; others may be agreed upon between interested parties.

8.3 *Site Patterns*

8.3.1 One-point — This can be useful for rapidly reviewing results of a quantity of wafers. This is often at the wafer centerpoint.

8.3.2 In applications where only a small number of locations are to be measured, the pattern and orientation of the local scans have to be identified. Measurements are performed at locations as outlined in Figure 1. For each local scan, a representative roughness is calculated. The wafer's representative roughness is then a function of the *n* individual representative scan values. The roughness variation can be calculated by the average, the standard deviation, the maximum or the range (Max-Min) of the individual scan values. Other statistical approaches may be employed.

8.3.3 Standard patterns include:

a. 1-point Wafer center,

b. 5-point Wafer Center plus four points at 2r/3 from the wafer center, and

c. 9-point Wafer Center plus four points at 2r/5 and four at 4r/5 from the wafer center.

NOTE 4: These patterns have been shown to be useful with a range of symmetries and values. See Related Information.

8.3.4 Standard measurement orientation patterns include:

a. Type A - linear scans parallel and perpendicular to the fiducial bisector, and

b. Type B - linear scans at 45° relative to the fiducial bisector.

NOTE 5: Type A is generally used for all surfaces. Type B has been reported to be useful for some surface conditions on (111) wafers.

8.4 *Bandwidth*

8.4.1 Two issues affect the bandwidth of the roughness results. The first is the bandwidth of the roughness measuring tool, which is discussed in Section 7. The second bandwidth effect is from the analysis software, which is user selected to emphasize certain spatial frequencies. Both long and short spatial wavelength (or frequency) limits must be defined in µm (or μm^{-1}). When entering this information into a measurement, specification wavelength units shall be used. Profiling instruments should have scan length and bandwidth adjusted according to DIN 4768 and 4777 or ASME B46.1.

8.5 *Precision*

8.5.1 The precision of the roughness measuring instrument (*P*) is important. The relationship between *P* and the tolerance of the parts to be characterized (*T*) is often called the *P/T* Ratio. SEMI M27 describes how to determine and interpret the factors: "A test instrument is usually deemed to be suitable for the purpose if P/T lies below 10%. If *P/T* is greater than 30%, the test instrument is not likely to be suitable for the purpose. Cases for which *P/T* lies between 10% and 30% must be judged on an individual basis, depending on the requirements being placed on the measurement system."

9 Roughness Measurement Specifications

9.1 The process of defining the measurements to be taken involves several distinct steps. The definition sequence below represents one logical sequence; others may be equally useful. See Table 1 for measurement abbreviations.

9.2 First, select the type of instrument to be used, including ALL of the following:

9.2.1 Generic instrument type

9.2.1.1 Interferometer

a. Interference microscope

9.2.1.2 Profilometer

a. AFM

b. Other scanning probe microscopes

c. Optical profilometer

d. Mechanical stylus

9.2.1.3 Scatterometer

a. Total Integrating (TIS)

b. Angle-resolved light (ARLS)

c. Scanning Surface Inspection System (SSIS)

9.3 Next, select the roughness parameter to by calculated.

9.4 Select the measurement pattern (Figure 1):

a. Center point

b. 5-point

c. 9-point

d. Full-FQA raster scan

e. Full-FQA R-theta scan

9.5 Select the pattern orientation (Figure 1)

a. Type A

b. Type B

9.6 Select the local measuring condition

a. Point

b. Line

c. Area

9.7 Specify the measurement calculations to be reported

a. Average (A)

b. Range (R)

c. Maximum (M)

d. Standard Deviation, 1 sigma (S_{n-1})

9.8 Specify the bandwidth and scan length limits within which data is to be gathered.

9.9 Lastly, record the abbreviations describing these selections (see Appendix 1 for examples), separating adjacent abbreviations with a comma and using periods for decimal notation. This creates a seven-field abbreviation. The field sequence described above follows the order of elements in Table 1.

10 Measurement Reporting Sequence

10.1 In general, one value is reported for a wafer. Where more than one pattern is specified the calculated values are reported in the order in which they are listed in Table 1.

Table 1 Roughness Measurement Codes

Element	*Abbreviation Item*					
Instrument	A Profilometer	1 AFM	2 SPM	3 OPR	4 MPR	
	B Interferometer	1 IM				
	C Scatterometer	1 TIS	2 ARLS	3 SSIS		
Pattern (See NOTE 1.)	1 Center	5 5-point	9 9-point	R FQA/Raster scan	C FQA/Concentric R-theta scan	S FQA/Spiral R-theta scan
Pattern Orientation	A A	B B				
Local Measurement Condition	P Point	L Line	A Area			
Parameter (See NOTE 1.)	Q Rq	A Ra	Z Rz	T Rt	K Kurtosis	S Skewness
Calculation (See NOTE 1.)	A Average	R Range	M Maximum	D Std. Deviation (1 sigma $_{n-1}$)		
Bandwidth, µm	[__]/[__] (fill in blanks to two significant figures) Long wavelength (µm)/Short wavelength (µm)					

NOTE 1: If more than 1 element is specified, the representative letters are concatenated in the relevant field, in the order specified. See Appendix 1 for examples.

Table 2 Scan Pattern Locations

Location		*X, Y Coordinates (per SEMI M20)*	*Scan Direction (for line and area tools), parallel to:*
Center Point		0, 0	Y-axis
5-point Pattern			
Point #	Location		
1	Center Point	0, 0	Y-axis
2	2r/3	0, 2r/3	Y-axis
3	2r/3	-2r/3, 0	X-axis
4	2r/3	0, -2r/3	Y-axis
5	2r/3	2r/3, 0	X-axis
9-point Pattern			
1	Center	0, 0	Y-axis
2	4r/5	0, 4r/5	Y-axis
3	4r/5	-4r/5, 0	X-axis
4	4r/5	0, -4r/5	Y-axis
5	4r/5	4r/5, 0	X-axis
6	$(r\sqrt{2})/5$	$(r\sqrt{2})/5, (r\sqrt{2})/5$	Y-axis
7	$(r\sqrt{2})/5$	$-(r\sqrt{2})/5, (r\sqrt{2})/5$	X-axis
8	$(r\sqrt{2})/5$	$-(r\sqrt{2})/5, -(r\sqrt{2})/5$	Y-axis
9	$(r\sqrt{2})/5$	$(r\sqrt{2})/5, -(r\sqrt{2})/5$	X-axis
Full FQA Scan			
Raster Scan		Full FQA	X-axis
Concentric Circles or Spiral		Full FQA	R – Theta

Patterns of Locations on a Silicon Wafer Surface for Measuring
(NOTE: R-Theta scan may be implemented in either a circular or a spiral pattern.)

APPENDIX 1

NOTE: The material in this appendix is an official part of SEMI M40 and was approved by full letter ballot procedures on December 15, 1999 by the North American Regional Standards Committee.

A1-1 Examples of Roughness Measurement Specifications and Related Output

The construction of typical measurement specifications and reported results are shown below. These could be the input to and output from a suitably equipped metrology tool, or directions for manual execution and reporting of the measurement and calculation sequence. The elements and codes are listed only in the first example. The quantitative data below is presented for illustration only, it does not represent actual instrument or sample measurements.

1. Mechanical Profiler

   The Mechanical profiler measurement was specified as MPR,5,L,A,A,A,250/10. This corresponds to measuring a 5-point pattern with a local line-scan and with pattern orientation A, and reporting Ra average value over a bandwidth from 250 to 10 µm.

Elements	Profiler, Mechanical;	5-point;	line-scan;	orient A;	Ra;	average;	250/10 µm
Codes	MPR	5	L	A	A	A	250/10
Output Example	MPR,5,L,A,A,A,250/10 = 0.53 nm						

2. Angle-Resolved Light Scattering

   The Angle-resolved light scattering instrument measurement was specified as ARLS,9,B,P,Q,A,40/2.0. This corresponds to measuring a 9-point pattern with a single spot and with pattern orientation B, reporting rms (Rq) average value over a bandwidth from 40 to 2 µm.

   Output Example ARLS,9,B,P,Q,A,40/2.0 = 0.15 nm

3. Interference Microscope

   The Interference microscope measurement was specified as IM,5,A,A,T,D,250/10. This corresponds to measuring a 5-point pattern with a local area and with pattern orientation A, reporting peak-to-valley (Rt) standard deviation over a bandwidth from 250 to 10 µm.

   Output Example IM,5,A,A,T,D,250/10 = 0.05 nm

4. Total Integrated Scattering

   The Total Integrated Scattering system (TIS) measurement was specified as TIS,S,P,A,Q,D,38/0.50. This corresponds to measuring a full FQA/spiral scan with a local spot and with pattern orientation A, reporting rms (Rq) standard deviation over a bandwidth from 38 to 0.5 µm.

   Output Example TIS,S,P,A,Q,D,38/0.50 = 0.02 nm

5. Optical Profiler

   The Optical Profiler measurement was specified as OPR,9,L,B,A,AD,80/0.50. This corresponds to measuring a 9 point pattern with a local line-scan and with pattern orientation B, reporting Ra average value and standard deviation over a bandwidth from 80 to 0.5 µm.

   Output Example OPR,9,L,B,A,AD,80/0.50 = 0.17nm (Ra average), 0.02 nm (Ra, standard deviation)

6. AFM

   The AFM measurement was specified as AFM,5,A,A,Z,A,20/0.04. This corresponds to measuring a 5 point pattern with local area and with pattern orientation A, reporting Rz average value over a bandwidth from 20 to 0.040 µm.

   Output Example AFM,5,A,A,Z,A,20/0.04 = 0.43 nm

RELATED INFORMATION 1
EXPERIMENTS AND MODELS RELATING TO ROUGHNESS DISTRIBUTION OF SILICON WAFERS

NOTE: This related information is not an official part of SEMI M40 but was approved for publication by full letter ballot procedures.

R1-1 Executive Summary

R1-1.1 Roughness is measured traditionally only on selected spots on a surface and only a few methods, such as light scattering, are practical for a complete surface scan. Therefore a systematic, standardized approach is required for defining the roughness of the entire surface of a silicon wafer. This can be done by defining one or several patterns of measurement spots which represent the entire surface so that the deviation of the average roughness and its standard deviation from the "true" values are small. The task of finding such patterns and verifying that they represent the entire surface was approached in two steps: 1. by investigating various patterns on various wafer surfaces experimentally, and 2. by simulating the roughness map of surfaces and by applying the selected patterns to them.

R1-1.2 Five different site patterns were used for the experimental investigation of silicon wafer surfaces which were final polished, stock removal polished and acid etched. The patterns consist of one, five, nine, ten and thirteen points (thirteen being the sum of a five and nine point pattern), respectively, and the measurements were performed with 10, 30, 80 and 250 µm filter lengths. Therefore 20 average roughness values and corresponding standard deviations were obtained for every wafer investigated, five for any filter length.

R1-1.3 Haze maps of these surfaces either displayed no variation, variations with an approximately rotational symmetry or a gradient across the surface, respectively. The average roughness of the surfaces measured with the various site patterns varied over four and a half orders of magnitude for the set of wafers used and the filter settings selected. The corresponding standard deviations were found to be <10% of the average roughness with the exception of four 200 mm final polished wafers where standard deviations up to 50-60% occurred. The 5-, 9- and 10-point site patterns were compared with respect to the average roughness and the corresponding standard deviation for every wafer. The variation (standard deviation) of the average roughness and the standard deviations as measured were found to be smaller than or approximately 10% in any case when normalized to the total average roughness of the corresponding wafer (average over all points of all patterns for a wafer).

R1-1.4 Roughness maps were generated for the simulation according to three different models: maps with a roughness pattern with rotational symmetry, with a linear gradient and with mirror symmetry. Two maps with a pixel size of 1 mm^2 were generated for each surface to take into account any anisotropy of the roughness, and center roughness and edge roughness, respectively, were used as free parameters for both maps. These parameters were varied between two level (0.1 and 0.2) for both maps resulting in a 2^5 factorial design of "experiment" where the symmetry was considered as 5^{th} parameter. The 1-, 5- and 9-point site patterns were applied to the various maps and the average roughness and standard deviation of roughness were calculated as well as the true values using all points of a map. Strong effects were observed for the 1-point pattern. As expected one point in the wafer center does in general not represent the average roughness of the entire surface reasonably well. The 5-point measurement provides the correct average ± 6%, the 9-point measurement is ± 2.5%. Similarly, the 5-point standard deviation is correct ± 1.6% and the 9-point one is ± 1%. Second order effects were found to be smaller than the main effects. Therefore it is concluded that the suggested five and nine point measurement patterns provide a good estimate of the roughness of an entire surface and its variations for reasonably homogeneous Si wafer surfaces.

R1-2 Introduction

R1-2.1 Roughness measurement of surfaces is performed with a variety of techniques, the most common ones being mechanical or optical profiling in real space or light scattering in reciprocal space (1,2,3). The numerical result of a roughness measurement process depends significantly on several parameters such as spatial bandwidth of the response function of the tool used including filtering, scan length, probe diameter, scanning speed etc. These parameters are not independent of each other and have been standardized only for mechanical profilers (e.g.4,5). The roughness values reported by different types of tools usually do not agree but they correlate provided their parameters were set up not too differently (6). The standardized roughness metrics such as average roughness R_a or root-mean-square roughness R_q refer mainly to line scans as performed by profiling techniques (e.g. 7). Area scans performed by profiling tools by aligning a series of line scans are usually very slow. Scanning the entire surface of a Si wafer with a profiler therefore would consume many hours, in the case of AFM (Atomic Force Microscope) many years.

R1-2.2 Techniques based on light scattering are capable of scanning the entire wafer surface quite rapidly, in about 1-2 min. Their response function, however, has a limited spatial bandwidth ranging approximately from 0.5 to 40 µm. Standards for light scattering measurements are now emerging (8,9).

R1-2.3 The obvious solution for obtaining a standardized roughness value of an entire surface is a) to define a pattern of sites where one- or two-dimensional scans are performed and b) to report the significant parameters along with the measurement (roughness) result. The second task can be solved theoretically by collecting the important parameters and by designing an appropriate abbreviation code. The first task requires experiments to collect data about the variation of roughness across a typical, real wafer surface and numerical simulations to find a set of sites the roughness of which agrees sufficiently well with the roughness of the entire surface.

R1-2.4 This appendix reports the results of corresponding roughness measurements as well as of a numerical simulation using a virtual design-of-experiment (DOX).

R1-3 Roughness Definitions

R1-3.1 A variety of definitions for roughness have been standardized by national and international institutions in the US, Japan and Europe. Corresponding standards are listed in section 5 of the main document and some selected ones again in reference 7. Most widely used are average roughness R_a and root-mean-square roughness R_q. Both refer to the average deviation of a profile from a reference line.

R1-4 Roughness Measurements

R1-4.1 *Experimental Details*

R1-4.1.1 Four groups of four wafers each were investigated to collect data about the variation of roughness across the wafer surface. The wafers were selected to represent different process steps and polishing techniques:

a) final polished wafers, 150 mm, #1-4
b) final polished wafers, 200 mm, #4-8
c) pre-polished wafers, 200 mm, #9-12
d) acid-etched wafers, 200 mm, #13-16.

R1-4.1.2 The wafers were characterized for haze with an SSIS (Censor ANS-100) and the roughness measurements were performed with an optical non-contact profiler (Chapman MP-2000+). The roughness data were taken by performing scans of length 3 mm and were evaluated using filters of 19, 30, 80 and 250 µm, respectively. The scans were performed at a variety of sites according to four different site patterns as displayed in Figure R1-1 where also the directions of the various scans are indicated:

i) center of wafer, one scan
ii) five points, center of wafer plus four points at 2/3 of radius
iii) nine points, center of wafer plus four points at 2/5 of radius plus four points at 4/5 of radius
iv) ten points, two in the center of wafer plus four points at ½ of radius and four points at radius minus 10 mm.
v) thirteen points, combination of pattern ii and iii.

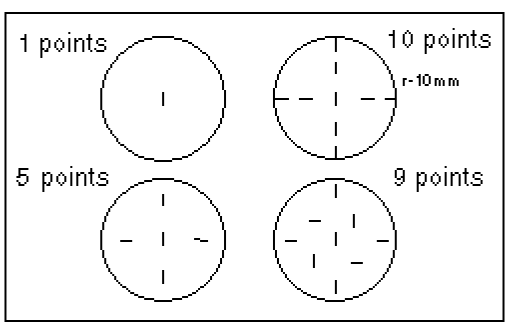

Figure R1-1
Site Patterns

R1-4.2 *Results*

R1-4.2.1 The average values of each site pattern is reported here together with the corresponding standard deviation. The average might be considered as the characteristic roughness of the entire surface whereas the standard deviation is a measure of roughness inhomogeneity. The results are summarized in Tables R1-1 and R1-3. These averages and standard deviations are called site average or site standard deviation for the respective site patterns for each wafer and each filter length applied.

R1-4.2.2 The variation in average values obtained with the different site patterns employed can be obtained by calculating 1) the average ofthe individual site averages and the standard deviation for each wafer and 2) the average of the individual site standard deviations and the corresponding standard deviation. These averages are called wafer average and wafer standard deviation, respectively. The corresponding standard deviations are called standard deviation of wafer average and standard deviation of wafer standard deviation. They are reported in Table R1-3 and Table R1-5 and in Figure R1-2 and Figure R1-3.

R1-4.2.3 The site average roughness values found range from 0.09 A for final polished wafers to 350 A for acid etched wafers for a 10 µm filter and from about 5 A to 2200 A, respectively, for a 250 µm filter. In total, a range of about four and a half orders of magnitude is covered. The site standard deviation for the different site patterns is around 10-15% of the average roughness of the wafer indicating a homogeneous roughness of the wafer surfaces. The difference between the site patterns ii, iii, iv and v for the relative site standard deviation is small, typically about 1-2 %. Exceptions are for the 200 mm final polished wafers with standard deviations of about 50-60% for the 10 µm filter.

R1-4.2.4 According to the values in Tables R1-3 & R1-5, the standard deviations of the wafer averages are less than 10 % in any case (Figure RI). The standard deviations of the various site standard deviations (Figure A3) are also smaller than or about 10 % with respect to the wafer average. This indicates that in the present case any site pattern —with the exception of the single site measurement at the wafer center—represents the “true” mean roughness of the entire surface and its standard deviation reasonably well.

Table R1-1 Results of Roughness Measurements, 10 and 30 µm Filters

	Wfr #	*Average/Standard Deviation, A 10 µm Filter*					*Average/Standard Deviation, A 30 µm Filter*				
Site pattern		i	ii	iii	iv	v	i	ii	iii	iv	v
Final polished, 150 mm	1	0.08	0.086/ 0.005	0.089/ 0.009	0.090/ 0.007	0.086/ 0.008	0.36	0.390/ 0.020	0.396/ 0.030	0.389/ 0.028	0.396/ 0.025
	2	0.09	0.090/ 0.007	0.094/ 0.010	0.090/ 0.005	0.093/ 0.009	0.43	0.408/ 0.037	0.413/ 0.035	0.410/ 0.028	0.410/ 0.035

R1-5 Models of Roughness Distribution and their Evaluation with a Virtual Experiment of Factorial Design

R1-5.1 *Goal of the Simulation*

R1-5.1.1 Roughness is measured on the entire wafer surface only in rare cases. Therefore approximations have to be found which represent the roughness of an entire wafer surface with appropriate accuracy. Three discrete site patterns were defined in section 9 of SEMI M40, which are thought to provide such approximations. Performing many measurements using these site patterns is one approach to assess these site patterns with respect to their validity. Another approach is to simulate roughness variations across a wafer surface and apply the site patterns to them. This allows easy and systematic variations of the surface roughness properties and maps. The assessment of the results again has to be performed in a systematic way. An appropriate tool for doing this is to utilize a factorial design for the variables in the various surface models used. The goal of finding a site pattern which represents the entire surface is considered to be achieved when the variations of the variables of the different surface models result in a non-significant effect in the evaluation of the factorial design.

R1-5.2 *Simulation of Roughness Maps*

R1-5.2.1 The measurement results that are reported in section 3 provide some insight into the variation of roughness that occurs across actual, typical wafer surfaces. The variation observed on the different wafers is related to the specific polishing technique (wax mount polishing, wax free polishing) and to the polishing parameters used. Examination of haze maps reveals three basic patterns of variation:

a) a circularly symmetric haze variation
b) a haze variation approximately symmetric with respect to a diameter across the wafer
c) a linear gradient of haze from one wafer edge to the opposite one.

R1-5.2.2 The following relations were used to simulate the variation of roughness according to these three basic models a)-c) with e and c being the roughness values near the edge and at the center of a wafer, respectively:

model a: a parabolic relation
$z(x,y) = (x^2+y^2)\,(e-c)/r^2 + c$ (equ. 1)

model b: a semi-cylindrical relation
$z(x,y) = (r^2-(y \cos a - x \sin a)^2)^{1/2}\,(e-c)/r + e$

(equ. 2)

model c: a linear gradient
$z(x,y) = (y \cos a - x \sin a)\,(e-c)/r + c$ (equ. 3)

with wafer radius r and angle α corresponding to the angle between the symmetry plane and the x-direction (model b) or the direction of the gradient and the y-direction (model c).

R1-5.2.3 Using equations 1-3, roughness maps of wafer surfaces can be generated with a roughness value assigned to each site. This was performed by using MathCad® software and by assuming 200 mm wafers, the area of each being partitioned into sites of 1 mm^2 size.

R1-5.2.4 Roughness is not necessarily an isotropic property of a surface. Different roughness values are in general obtained when e.g. two scans are performed at the same spot on a wafer surface but in perpendicular directions. Therefore two maps representing the roughness anisotropy were generated in each case by assuming two sets of the parameters e and c – e1, c1, e2, and c2, per wafer surface.

R1-5.3 *Factorial Design*

R1-5.3.1 A factorial design at two levels was selected in order to compare the various wafer maps generated (10). The parameters ei and ci (i = 1,2) were used as variables and were varied between two levels, 0.1 and 0.2, in arbitrary units. In addition the patterns (models a – c) were also used as a variable and the values –1 and +1 were correspondingly assigned resulting in a 2^5 factorial design. The complete set of parameters used is displayed in Table R1-5.

Table R1-5 Complete Set of Parameters Used in the 2^5 Factorial Design

R1-5.3.2 Wafer roughness maps with 1 mm^2 pixel size were generated using all possible 32 combinations of the parameters in Table R1-5. Average roughness and standard deviation were calculated by using all pixels of a map (avgtrue, stdabwtrue) as well as by using the three discrete site patterns displayed in Figure 1 of the main part of this document (avg1, avg5, avg9, stdabw5, stdabw9). Corresponding results for comparing models a and b are displayed in Table R1-6. These values were normalized for further evaluation, the averages with respect to avgtrue (ravgi=avgi/avgtrue, i=1,5,9), the standard deviations with respect to their difference to the "true" value ((rstdabwi=stdabwi.-stdabwtrue) / stdabwtrue, i=5,9) (Table R1-7). Results for comparing models a and c are similar and are not reported here in detail.

R1-5.3.3 The averages for ravg1,5,9 over the various variable sets differ by less than 1% from unity. The corresponding standard deviations decrease from 27% to 5% going from ravg1 to ravg9, respectively, indicating — as one would expect — that ravg9 is a much more precise value for the roughness of the entire surface as compared to ravg1 or ravg5. The relative standard deviations rstdabw5,9 deviate in the average by about 12% from the true value. The corresponding standard deviations differ not much for rstdabw5 and rstdabw9.

R1-5.3.4 More detailed information is obtained when the results are evaluated according to the factorial design used. The 1st to 5th order effects of varying the variables were calculated by applying using a table of contrast coefficients /10/ to the normalized results of the simulation. The 1st order — or main — effects are the difference of the observations for both levels of one parameter and averages over all other observations. They measure the average effect of a variable over all conditions of the other variables. The 2nd order effects are a measure for the interaction of variables and are obtained by calculating one half of the difference of the average effect of variable 1 with variable 2 at level 1 and variable 1 with variable 2 at level 2. 3rd order and higher effects are not considered in the present work. They are assumed to be negligible and are used to calculate the variance of an effect (=square root of the average of the squares of 3rd to 5th order effects).

R1-5.3.5 The result of this evaluation is displayed in Table R1-8 and Table R1-9 for the main (1st order) and 2nd order effects, respectively.

Table R1-8 Average (over all sets of variables) and Main Effects of the Various Variables on the Observables (The variance as calculated from the 2nd to 5th order effects is displayed in the last column.)

	Average	*c1*	*e1*	*c2*	*e2*	*Sym.*	*Variance*
ravg1	0.9968	0.4482	-0.1111	-0.2237	-0.1111	-0.0064	4.16E-05
ravg5	0.9987	0.1134	-0.0460	-0.0377	-0.0287	-0.0027	3.69E-06

rstdabw5	0.1287	-0.0038	-0.0049	-0.0073	-0.0080	0.0315	3.43E-04
rstdabw9	0.1254	-0.0064	-0.0057	-0.0113	-0.0052	0.0198	4.87E-04

Table R1-9 2nd Order Effects (The variance as calculated from the 2nd to 5th order effects is displayed in the last column.)

	c1/e1	*c1/c2*	*c1/e2*	*c1/sym*	*e1/c2*	*e1/e2*	*e1/sym*	*c2/e2*	*c2/sym*	*e2/sym*	*Variance*
ravg1	-0.0157	-0.0221	-0.0157	-0.0590	0.0218	0.0160	0.0579	0.0218	-0.0547	0.0579	4.16E-05
ravg5	-0.0015	-0.0079	-0.0040	-0.0067	0.0065	0.0054	0.0064	0.0039	-0.0225	0.0238	3.69E-06
ravg9	-0.0003	0.0023	-0.0057	0.0304	0.0049	-0.0015	-0.0304	-0.0005	-0.0092	0.0119	4.37E-06
rstdabw5	-0.0062	-0.1848	-0.0603	-0.0027	-0.0423	-0.0392	0.0059	0.0335	-0.0005	0.0029	3.43E-04
rstdabw9	0.0080	-0.1471	-0.0722	0.0002	-0.0247	-0.0894	0.0003	0.0518	0.0027	0.0008	4.87E-04

R1-5.3.6 The behavior of the main effects is also illustrated in Figure R1-5, where the variation of ravg1,5,9 and stdabw5,9 are plotted vs. the variables. The clear effect, on ravg1, of varying center1 between 0.1 and 0.2 is easy to understand as ravg1 consists only of one measurement point in the center of the wafer surface. Similar but less pronounced effects are observed for ravg5 and 9. Note that the opposite effect occurs for center 2 as this point is not included in calculating ravg1,5 or 9. Also note that the influence of the variables edge1 or edge2 is much less pronounced. In any case, the 5-point measurement provides the correct average ± 6%, the 9-point measurement ± 2.5%. In a similar way, the 5-point standard deviation is correct ± 1.6% and the 9-point standard deviation ± 1%.

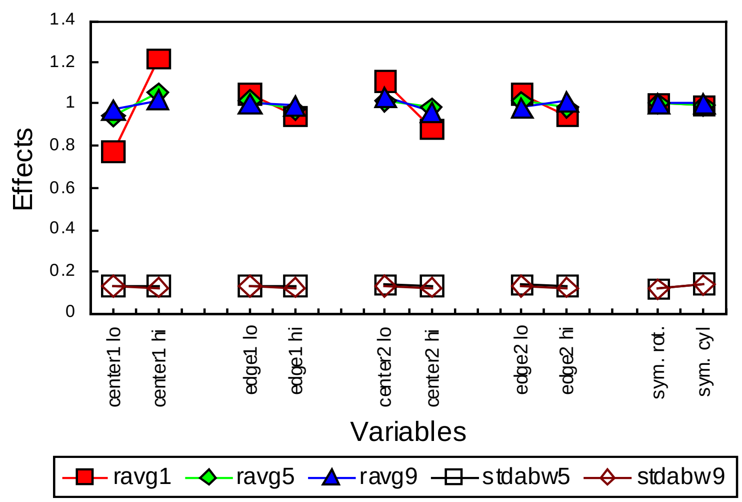

Figure R1-5
Main Effects of the 2^5 Factorial Design for Models a and b

R1-5.3.7 The significance of numbers given in Table R1-8 and Table R1-9 can be estimated only in relation to the noise or variance of the observables which is also displayed in both tables. The signal-to-noise ratio S/N is obtained by using a logarithmic measure:

$$S/N = 10 \log (\text{effect}^2/\text{variance})$$

R1-5.3.8 The corresponding S/N values for the main and for the second order effects are listed in Table R1-10 and Table R1-11.

R1-5.3.9 A linear signal-to-noise ratio of 3:1 is commonly used to distinguish significant data from insignificant data. This linear ratio corresponds to a S/N of about 10 in the present case of a logarithmic signal-to- noise ration. The S/N ratios > 10 are shaded lightly gray in Table R1-10 and Table R1-11. The variables center1,2 and edge1,2 have a significant effect on the relative averages ravg1,5,9. Mainly the interactions of the model selected with the other variables are significant for the relative averages ravg1,5,9 and the interaction of center1 and center2 for the relative standard deviations rstdabw5,9. The other cases emphasized in Table R1-11 by shading have a S/N ratio only slightly larger than 10.

Table R1-10 S/N Ratios for the Main Effects of Table R1-8

	average	*c1*	*e1*	*c2*	*e2*	*Sym*
ravg1	43.7817	36.8384	24.7251	30.8046	24.7251	-0.0364

rstdabw5	16.8383	-13.6750	-11.4959	-8.0646	-7.3246	4.6154
rstdabw9	15.0934	-10.7996	-11.7656	-5.7926	-12.5745	-0.9359

Table R1-11 S/N Ratios for the 2nd Order Effects of Table R1-9

	c1/e1	*c1/c2*	*c1/e2*	*c1/sym*	*e1/c2*	*e1/e2*	*e1/sym*	*c2/e2*	*c2/sym*	*e2/sym*
ravg1	7.7045	10.7110	7.7045	19.2237	10.5897	7.8732	19.0682	10.5897	18.5684	19.0682
ravg5	-2.3106	12.2743	6.3820	10.8291	10.5529	9.0162	10.4414	6.2417	21.3820	21.8517
ravg9	-17.0034	0.7278	8.7438	23.2512	7.3954	-3.1738	23.2558	-11.9623	12.8618	15.1361
Rstdabw5	-9.5587	19.9853	10.2575	-16.7484	7.1802	6.5178	-9.8910	5.1594	-32.1153	-16.1308
Rstdabw9	-8.8505	16.4782	10.2932	-40.5530	0.9730	12.1486	-37.1733	7.4191	-18.3336	-28.6846

R1-5.3.10 The interactions are discussed for two examples, ravg9 and rstdabw5 (Table R1-12). Going from sym lo (model a, parabolic symmetry) to sym hi (model b, cylindrical symmetry) and keeping c1 fixed at the lo level decreases ravg9 from 0.993 to 0.963 whereas it increases from 1.007 to 1.037 when c1 is kept fixed at the lo level. This change in opposite directions indicate an interaction between c1 and sym. c1 and c2 interact in a similar way with respect to rstdabw5.

Table R1-12 2nd Order Effects or Interactions

C1 lo/sym hi	0.963		1.037	c1 hi/sym hi
		ravg9		
C1 lo/sym lo	0.993		1.007	c1 hi/sym lo
c1 lo/c2 hi	0.219		0.031	c1 hi/c2 hi
		stdabw5		
c1 lo/c2 lo	0.132		0.223	c1 hi/c2 lo

R1-5.4 *Summary and Conclusions*

R1-5.4.1 Three different models for surface roughness distribution (roughness maps) were investigated and three different site patterns for measuring the roughness were applied to them. The parameters of the models – roughness in the center and near the edge of the wafer – were used as variables in a factorial design and varied between two levels. Average roughness and the corresponding standard deviations calculated for the site patterns were compared with the "true" values obtained by evaluating all points of the roughness map.

R1-5.4.2 The patterns where the roughness is measured at five or nine points exhibit a standard deviation of 7 and 5 %, respectively, from the true average value for all possible combinations of the variables. The average of the standard deviations of the roughness distribution of the single variable sets differs by about 13% from the true value for the five- as well as nine-point site pattern. A standard deviation of the standard deviations of about 11% is obtained by averaging over the 32 different variables sets.

R1-5.4.3 The evaluation of the factorial design outlines that the variation of the variables c1, c2, e1, and e2 has a significant effect – with respect to "noise" – on the average roughness values but not on the corresponding standard deviations. Varying the surface model does not significantly affect the averages and standard deviations. Some second order effects or interactions are also significant but less pronounced than the main effects. A pronounced interaction of the variables c1 and c2 occurs e.g. for the five point standard deviation rstdabw5. This interaction could be reduced by introducing an additional site for measuring roughness in the center of the wafer with a direction perpendicular to the present one.

R1-5.4.4 The goal of finding a site pattern which results only in non-significant effects is not completely achieved by the five and nine point patterns utilized in the present work. However, they allow to measure the average roughness of wide variety of surface roughness distributions with a one sigma deviation of 5-7 %, or a three sigma deviation of 15-21 %. These values are certainly more than sufficient for present wafer surfaces.

SEMI M41-1101
SPECIFICATION OF SILICON-ON-INSULATOR (SOI) FOR POWER DEVICE/ICs

This specification was technically approved by the Global Silicon Wafer Committee and is the direct responsibility of the Japanese Silicon Wafer Committee. Current edition approved by the Japanese Regional Standards Committee on August 3, 2001. Initially available at www.semi.org August 2001; to be published November 2001. Originally published June 2000; previously published July 2001.

1 Purpose

1.1 This specification covers requirements for silicon-on-insulator (SOI) for semiconductor power-device/IC manufacture. By defining inspection procedures and acceptance criteria, both users and suppliers may define product characteristics and quality requirements.

2 Scope

2.1 This specification provides requirements of SOI wafers, which are used for power devices/ICs of specific voltage applications. The voltage ranges cover low voltage (40–60V), medium voltage (150–250V) and high voltage (500–600V). The specification covers physical, electrical, and surface parameters pertinent to bonded wafers.

2.2 Included in this document is a list of goals for inspection of these wafers which need to be negotiated between the users and suppliers of bonded wafers.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

4 Terminology

4.1 Many terms relating to silicon technology are defined in ASTM Terminology F1241, "Terminology of Silicon Technology."

4.2 Other terms are defined as follows:

4.2.1 *base silicon wafer* — the silicon wafer below the insulator layer, supporting the top silicon film.

4.2.2 *bonded wafers* — defined as two silicon wafers bonded together with an insulating layer. This insulator layer is typically thermally grown silicon-dioxide.

4.2.3 *bonding interface* — the plane where the bonding between the two wafers takes place.

4.2.4 *buried oxide layer (BOX)* — the insulator layer between the two wafers when the insulator layer is silicon-dioxide.

4.2.5 *non-SOI edge area* — an annulus between the nominal radius of the surface silicon layer and the nominal radius of the base silicon wafer (for bonded SOI wafers). The annulus which implies an area is determined by its width as one dimension. It is the difference in the nominal radius of the surface silicon layer and that of the base silicon wafer.

4.2.6 *thickness of top silicon film* — the distance between the surface of the top silicon film and the top silicon film-buried oxide interface.

4.2.7 *top silicon film* — the silicon layer on top of the insulator film in which the semiconductor active devices are fabricated.

4.2.8 *void* — the absence of a chemical bond at the bonding interface.

5 Ordering Information

5.1 Purchase orders for bonded wafers furnished to this specification shall include the following items:

5.1.1 Substrate Characteristics for the device layer (*diameter, dopant, orientation, resistivity, Oi, etc.*)

5.1.2 Substrate Characteristics for the base wafer (*diameter, thickness, dopant, orientation, resistivity, etc.*)

3 Japanese Electronic and Information Technology Industries Association, Tokyo Chamber of Commerce and Industry Bldg. 2-2, Marunouchi 3-chome, Chiyoda-ku, Tokyo 100-0005, Japan. Website: www.jeita.or.jp

5.1.3 Buried oxide thickness and thickness tolerances

5.1.4 Top silicon film thickness and thickness tolerances

5.1.5 Warp limits

5.1.6 Top silicon film OSF defect limits

5.1.7 Top silicon film carrier life time limits

5.1.8 Buried oxide defect limits

5.1.9 Edge profile of the top silicon film and non-SOI edge area

5.1.10 Rotation alignment between top silicon film and the base silicon

5.1.11 Position of the bonding interface

5.1.12 Methods of test and measurements (see Sections 8 and 9)

5.1.13 Lot acceptance procedures (see Section 7)

5.1.14 Certification (if required)

5.1.15 Packing and marking (see Section 10)

NOTE 2: Verification test procedures of certification of these items shall be agreed upon between the users and the supplier (see Sections 8 and 9).

6 Requirements

6.1 The complete specifications for Overall Wafer, Top Silicon Film, Buried Oxide (BOX) and Base Silicon Wafer are listed in Tables 1 to 5.

Table 1 Silicon-on-Insulator (SOI) Specifications for Low Voltage (45–60V) Power Device (1)

Parameters (Units)	*Value*	*ASTM Test Method or Measurement Procedure*	*Acceptance*
Wafer(Overall)

Back Surface Finish	Note C	Optical Metrology	Note C

Note A: Same as the standard of regular silicon wafer
Note B: The value is of 150 mm wafers, and is determined according to wafer diameter.
Note C: To be determined by negotiation between wafer users and suppliers
Note D: Reflective spectroscopy or FT-IR is recommended for top silicon film of less than several µm (about 7 µm), and FT-IR for top silicon film of more than several µm (about 7 µm).
Note E: Tolerance of ± 0.5 µm is recommended for top silicon film of less than several µm (about 7 µm), and ± 1.0 µm for top silicon film of more than several µm (about 7 µm).
Note F: The value is without the compensation method by backside oxide.
Note G: The value is with the compensation method by backside oxide.
Note H: This item can be neglected if the bonding interface is between BOX and base wafer.

7 Sampling Plan

7.1 Unless otherwise specified, ASTM Practice E 122 shall be used. When so specified, appropriate sample sizes shall be selected from each lot in accordance with ANSI/ASQC Z1.4. Each quality characteristic shall be assigned an acceptable quality level (AQL) of lot tolerance percent defective (LTPD) value in accordance with ANSI/ASQC Z1.4 definitions for critical, major, and minor classifications. If desired and so specified in the contact or order, each of these classifications may alternatively be assigned cumulative AQL or LTPD values. Inspection levels shall be agreed upon between the users and the suppliers.

8 Test Methods - Dimensions

NOTE 3: Detailed test procedures of each item should be determined between the users and the suppliers.

8.1 *Thickness of Top Silicon Film* — The following two methods are available for thickness measurement.

8.1.1 *Reflective Spectroscopy* — The light of visual wavelength (400–800 nm) is introduced into top silicon film by varying its wavelength continuously, and then the reflective spectra is measured. When the light is introduced into multi-layers of SOI wafers, reflection occurs on the surface of top silicon film and the front and backside of BOX. In such a case, the phase varies. The final intensities of the light that reflects from top silicon film surface are the sum of the intensity of light that reflects from each layer. The thickness of top silicon film and BOX makes optical path difference and then results in phase difference that is dependent on its wave length. The reflective light intensities, depending on its wavelength, are measured. The reflective spectra are defined as the ratio of reflective light intensity to incident intensity. This spectra curve varies by the thickness of top silicon film and BOX. The top silicon film thickness is derived from the obtained spectra curve by approximate calculation based on simulation or by comparing with the database.

8.1.1.1 Reference: J.-P. Colinge, “Silicon-On-Insulator Technology”, Kluwer Academic Publisher, 1991.

NOTE 4: Thickness of top silicon film and BOX layer are limited to measure because of using visual light.

Example: Nanospec/AFT model : 210LCW, SP-FSC15

Top silicon film thickness: 0.01–15 µm

BOX thickness: 0.004–3 µm

NOTE 5: Optical constant is already known in each of multilayers, and it should be constant in the whole layer.

8.1.2 *FT-IR (Fourier Transform Infra-Red Spectrometry)* — The reflectance spectrum of the specimen, which exhibits successive maxima and minima characteristics of optical interference phenomena, is measured as a function of wavelength using an infrared spectrophotometer. These maxima and minima are observed when the optical path lengths of the infrared beam, reflected from both the top silicon film surface and the top silicon film–buried oxide interface, differ by an integral number of half wavelengths. Consequently, the thickness of top silicon film is calculated using the wavelength of the extreme maximum and minimum in reflectance spectrum, the refractive index of Silicon and Silicon dioxide, and the angle of incidence of the infrared beam upon the SOI wafer.

Reference: F95 – Standard Test Method for Thickness of Lightly Doped Silicon Epitaxial Layers on Heavily Doped Silicon Substrates Using an Infrared Dispersive Spectrophotometer

8.1.3 *Definition of top silicon film thickness tolerance* — Thickness tolerance is defined below.

8.1.3.1 After top silicon film thickness is measured at predetermined number of points within an SOI wafer, the maximum and the minimum values are chosen, and then the tolerance is defined as;

Tolerance = Maximum value – Minimum value

NOTE 6: The location and numbers of measuring points should be determined between users and suppliers.

8.1.3.2 In case of multi-points measurements (ex. a few hundreds) within an SOI wafer, the tolerance is defined as;

Tolerance = 3σ (3 times of the standard deviation)

8.1.3.3 Measurement exclusion area such as wafer edge should be determined between users and suppliers.

NOTE 7: Recommendable metrology

a) Reflective spectroscopy or FT-IR is recommended

- for top silicon film of less than several μm (about 7 μm),
- and FT-IR for top silicon film of more than several μm (about 7 μm)

b) Tolerance is defined as the difference between the maximum and the minimum value after measuring several (ex. 9) points.

c) It is not necessary to measure the BOX thickness of SOI wafer after bonding. It is OK to measure it before wafer bonding.

d) In case of the above 1) ~ 3), the number of measurement points and their location should be specified in case of several points measuring, and the measurement exclusion area should be specified in case of multi-points measuring.

8.2 *Crystal Defect of Top Silicon Film*

8.2.1 *OSF (Oxidation induced Stacking Fault)* — This technique is applicable to the top silicon film of thicker than 1.5 μm. OSF density is measured by preferential chemical etching and microscopic observation. Preparation of samples and measurement of OSF density are as follows:

8.2.1.1 *Sample Preparation* — SOI wafers are oxidized at 1,100°C, 1 h, in H_2 / O ambient after the SC-1 and SC-2 cleaning. Oxide is removed by ca. 25 % HF and then the SOI wafers are preferentially etched by 1 μm, applying JIS H 0609:1994(B), and then rinsed thoroughly in distilled water and blown dry. JIS H 0609 defines the chromium-free preferential solution, which is composed of HF, HNO_3, CH_3COOH and H_2O.

8.2.1.2 *Measurement of OSF Density* — Samples are examined by an optical microscope. The sample surface is observed by magnification of 200 X, and OSF is counted on SOI wafer within the scope along the two lines, which are parallel and perpendicular to the orientation flat (so called cross scanning). OSF density is calculated from the count number and scanning area.

8.3 *Buried Oxide Defect*

8.3.1 *Cu Decoration Method* — In case of Bonded SOI, the buried oxide is usually formed by thermal oxidation. Therefore, the defect of buried oxide is taken into consideration only for the thin oxide cases. Buried oxide defect such as pinholes can be evaluated by Cu decoration method. This method has been applied to the buried oxide film of less than 400 nm thickness. Sample preparation and Cu decoration are conducted by the following procedure. The top silicon film on the buried oxide is removed by KOH solution, and then cleaned and rinsed. The sample is set on a gold-plated brass (Cathode) in the methanol solution. On the other side, a copper plate (Anode) is placed 5 mm above the sample surface. Positive constant bias of 1–3 MV/cm (ex. 40–120 V for 400 nm oxide) is applied to the copper plate for 5 minutes. Small leakage current passes through the buried oxide defect, and consequently copper precipitates on the defects. Typical allowable defect density is < 0.1/cm^2.

8.4 *Metal Contamination*

8.4.1 The surface metal contamination can be measured by TXRF, AAS and ICP-MS methods.

8.4.2 *TXRF (Total X-Ray Fluorescence)* — Total X-ray Fluorescence uses a low angle incident, and a tightly collimated X-ray beam excites the characteristic X-rays from impurity atoms near the sample surface. Usually, the angle of X-ray incident is less than 0.1 degree. The element identification and the amount of the element can be obtained by measuring energy and intensities of fluorescence X-ray. The instrument provides a map of impurity element distribution. The surface metal contamination (typically from Na to Zn) shall be less than 10^{11} cm^{-2} in total.

NOTE 8: This TXRF method is conveniently used to detect the metals on the SOI wafer surface.

8.4.3 *AAS (Atomic Absorption Spectrophotometry)* — The elemental characteristic absorption of the atom is measured by introducing sample solution as aerosol into the flame and then spectral absorption through the flame from the light source is detected by the spectroscope. The flameless method, superior to the flame method in the sensitivity, is now broadly used.

8.4.3.1 *Sample Preparation* — Careful sample preparation is necessary for the precise measurement. SOI wafer surface is exposed to HF vapor, and the metals on the surface are collected as droplet. To improve the sensitivity, the volume of collective solution should be as tiny as possible and the HF drops are rolled all over the surface in collective operation. In case of precious metals, it is better to use other kinds of collective solutions instead, since they are not dissolved or collected by HF solution itself.

Examples:

For Cu; HF-H_2O_2 (HF : H_2O_2: H_2O = 1 : 17 : 82)

For Au and Pt; aqua regia (HNO_3 : HCl = 1 : 3)

8.4.4 *ICP-MS (Inductively Coupled Plasma Mass Spectrometry)* — ICP-MS is composed of ICP (Inductively Coupled Plasma) part as an ion source and MS (Mass Spectrometer) part, which measures the ions generated at ICP part. Usually, sample solution is vaporized in the nebulizer and then finally introduced into Argon plasma in the silica tube called torch through the spray chamber. The sample is decomposed, evaporated, atomized and then ionized in the Argon plasma. Except for few atoms that have relatively high ionization potential, most of the elements (> 90%) can be ionized. Ions are identified and measured in amount by the mass spectrometer.

8.4.4.1 *Sample Preparation* — The same method as AAS method is applicable. In case of quantitative measurement of Fe, since its mass weight is close to that of ArO^+, it is necessary to pay attention to the degradation of detection sensitivity.

8.5 *Particle Density (LPD : Light Point Defect)*

8.5.1 *Light Scattering Tomography* — The particle larger than 0.2 μm on the thick SOI wafers is counted by Automated particle counter. The particles in the order of 0.1 μm can be detected if top silicon film is sufficiently thick.

8.5.2 *Principle of measurement* — By scanning the laser beam on the wafer surface, the light scattered by the particles on the wafer is detected. The scattered light and the noise from the wafer surface is detected as a direct current, on the other hand, the scattered light by the particles can be detected as pulse components. The particle size can be calibrated with standard polystyrene latex spheres. Multi-layers of SOI wafers usually have scattering noise from the layer interface. In case of less than 1 μm of the top silicon film thickness, it is necessary to reduce incident angle of the laser beam to increase the reflective component from the surface. For example, S/N ratio is improved when using S-polarized light of 10 degree incident, 85% of its component is reflected from silicon surface.

NOTE 9: In case of SOI wafer (Thickness > 1 μm)

Particle counter with a vertical incident laser, which is the same one used for the bulk wafer, is applied. It should be noted that bypass filter to erase the interference signals due to thickness dispersion, and adjustment of photo-multiplier sensitivity are necessary. By this technique, it is capable of detecting particles (> 0.1μm) as much as on the bulk wafer.

NOTE 10: In case of SOI wafer (Thickness < 0.5 μm)

It is recommended to use S - polarized light or normal light with low incident angle because of high scattering noise. However, the adjustment of photo-multiplier sensitivity is necessary to reduce the noise component. The sensitivity depends on the magnitude of the noise and it is usually possible to detect particles of around more than 0.5μm (in bulk wafer, > 0.2 μm).

8.5.3 *Visual Inspection* — SOI wafer can be visually inspected in accordance with ASTM F523. The automatic inspection equipment is also used when available. For visual inspection, the collimated high intensity bright light (ex. 500,000 lux) is used. Under using this light, SOI wafer is inspected for haze, slip, scratches, chips, cracks, pits, dimples, mound, orange peel, LPD and contamination.

8.6 *Surface Roughness*

8.6.1 *AFM (Atomic Force Microscope)* — By contacting the probe equipped with the cantilever onto the wafer surface of the sample, and by scanning the cantilever and detecting the variation by i.e., optical method, the roughness information is obtained.

NOTE 11: It is expected to set the observation area as > 20 μm × 20 μm to increase reliability of the data.

NOTE 12: Height calibration of concave and convex: Refer to UC standard ("Calibration method of 1 μm order height in AFM", [Ultra Clean Technology, Vol. 7, No. 2, pp. 43, 1995]).

8.7 *Inclusions*

8.7.1 In bonded SOI wafer, there exists the contaminants at the bonding Si/SiO_2 or SiO_2/SiO_2 interface such as particles, metals, boron, and hydrocarbon. Here, inclusions means the contaminants. Although there has been no report on the influence of contaminants to the device characteristics, the improvement of the contamination level is required.

8.8 *Void*

8.8.1 *Scanning Acoustic Topography* — The void can be detected by means of the traveling time difference of the acoustic waves. The void mapping can be made by scanning an ultrasonic wave and detecting the reflecting wave from the both surfaces of the void. Measuring in water improves the resolving power of location since the ultrasonic wave can be tightened by acoustic lenses.

NOTE 13: It is not suitable to measure SOI wafer that is not bonded firmly because measurement is conducted in water.

NOTE 14: It is not suitable to measure top silicon film (< 7 μm) because it is impossible to separate reflective waves both from top silicon film surface and the bonding interface.

NOTE 15: Detectable void gap depends on acoustic wave frequency. Detectable void diameter depends on the size of the acoustic source and the receiver. For example, if using 75

MHz frequency, 5 nm void gap and 50 µm void diameter can be detected.

NOTE 16: Void is defined as “empty space” that is due to the imperfect bonding at Si/SiO_2 and SiO_2/ SiO_2 interface. This void should be discriminated from the splitting at bonding strength test.

NOTE 17: Void can be only evaluated during SOI wafer processing, not at the shipping.

8.9 *Bonding Strength*

8.9.1 *Tensile Testing Method* — Bonding strength is defined and evaluated by tensile strength (kgf/cm^2) which is needed to split the bonding interface vertically. Details of the test structure and the test method should be determined by negotiation between wafer users and wafer suppliers.

Table 6 Test Summary Table

Parameter	*Reference*	*Method*
Wafer Diameter	F613-93	Optical Comparator
Wafer Thickness	F533-96, F1530-94	Thick. Gage, Auto. Noncontact Scan.
Total Thickness Variation LTV	F1530-94	Automated Noncontact Scanning
Warp	F1390-92	Automated Noncontact Scanning
Crystal Orientation Top Silicon Film (SOI) Base Wafer	F26-87a (1993)	X-ray Diffraction
Substrate Type / Dopant	F42-93	Hot-Probe (Test Method A)
Substrate Resistivity	F43-93, F84-93, F1527-94	4 Point Probe
Substrate RRG	F81-95	4 Point Probe
Top Si Film Thickness	Section 8.1	Reflective Spectroscopy or FTIR
Crystal Defect (OSF)	Section 8.2, (JIS H 0609 :1994 B)	Cr-free Etch / Optical Microscopy
Buried Ox defects	Section 8.3, (SEMI M34)	(a) Cu Decoration, (b) BOX Capacitor
Metal Contamination (per unit area)	Section 8.4, (F1526-95)	TXRF, AAS/ICP-MS
Particle Density (LPD)	Section 8.5 (F1620-96)	Light Scattering Tomography (Automated Particle Counter)
Haze	F523-93 (see NOTE 1), F154-94	Visual Inspection
Slip	F523-93 (see NOTE 1), F154-94	Visual Inspection
Scratches	F523-93 (see NOTE 1), F154-94	Visual Inspection
Chips / Cracks	F523-93 (see NOTE 1), F154-94	Visual Inspection
Pits and Dimples	F523-93 (see NOTE 1), F154-94	Visual Inspection
Mounds	F523-93 (see NOTE 1), F154-94	Visual Inspection
Orange peel	F523-93 (see NOTE 1), F154-94	Visual Inspection
Particle Density (LPD)	F523-93 (see NOTE 1), F154-94	Visual Inspection
Contamination (Both Side)	F523-93 (see NOTE 1), F154-94	Visual Inspection
Surface Roughness	Section 8.6	AFM
Inclusions	Section 8.7	SIMS
Voids	Section 8.8	Scanning Acoustic Tomography
Bonding Strength	Section 8.9	Tensile Strength

NOTE 1: Users and suppliers may agree on the non-SOI edge area for these specifications. For example the area within 6 mm proximity of the wafer edge may be excluded.

Table 7 Example: Soi Wafer Surface Visual Inspection Criteria

Criterion Items	*Allowed Quantity (Per 150 mm Wafer)*	*Description*
Haze	NONE	
Slip	< 4 2 mm width and < 15 mm length	
Scratches	NONE	
Chips / Cracks	< 3 for @ 0.5 mm circumferential x 0.3 mm length	Edge : Base Wafer
Pits and Dimples	NONE	
Particle Density (LPD)	< 30 for @ > 0.2 µm	<0.17 / cm^2 for 150 mm Wafer
Contamination	NONE	Both Surface and Backside

NOTE 1: The surface visual inspection is conducted under the collimated bright light.
NOTE 2: Non-SOI edge area (E.E.) of 6 mm is applied to the criterion items except for edge chips/cracks.
NOTE 3: The whole wafer (Top silicon film and Base wafer) is inspected except for edge chips/cracks.

Table 8 Soi Electrical Parameters

Parameters	*Reference*	*Value*	*Method*
Photo-conductivity Lifetime	Section 9.1	To be determined	µ-PCD
BOX Breakdown	Section 9.2	To be determined	I-V
BOX Charge	Section 9.3	To be determined	C-V
BOX Surface States	Section 9.4	To be determined	C-V
Doping Density Top silicon film, Base wafer	Section 9.5	To be determined	SIMS or 4 pt. probe

9 Electrical Parameters

9.1 *Photo-conductivity Lifetime*

9.1.1 *Test Method: µ-PCD method*

9.1.1.1 Excess carriers that are created in the wafer by a light pulse increases the conductivity of the sample. When the light is turned off, the conductivity is decreased by the carrier recombination. This phenom-enon is monitored by means of microwave reflectance. The microwave detects an exponential decay in conduc-tivity, from which a decay constant is determined.

9.1.2 The effective recombination lifetime τ_{eff} is given by the following expression:

$$1/\tau_{eff} = 1/\tau_B + 1/(\tau_S + \tau_D)$$

$$\tau_S = d/(S_{Si/Box} + S_{Si}),\ \tau_D = d/\pi^2 D$$

Where τ_B is bulk recombination lifetime, τ_S is surface recombination lifetime, τ_D is diffusion lifetime, $S_{Si/Box}$ is recombination velocity at the Box interface, S_{Si} is recombination velocity at the silicon surface, D is diffusion coefficient and d is top silicon film thickness.

9.1.3 The wavelength of the light has to be selected, depending on the top silicon film thickness (see Table 9).

9.2 *Box Breakdown Voltage*

9.2.1 *Test Structure* — Box capacitor having an area (Ex. 1 cm^2).

9.2.2 *Test Method: Staircase I-V Measurement* — Voltage is stepwise increased in one-volt increments from zero to the (+/-) specified voltage. Details of the test structure and the test method are determined by negotiation between wafer users and wafer suppliers.

9.3 *Box Charge*

9.3.1 *Test Structure* — Box capacitor having an area (Ex. 1 cm^2).

9.3.2 *Test method* — MOS high-frequency C-V measurement of a Box capacitor normally yields a flat band voltage. Details of the test structure and the test method are determined by negotiation between wafer users and wafer suppliers.

9.4 *Buried Oxide Fast Interfaces State Density*

9.4.1 *Test Structure* — Box capacitor having an area. (Ex. 1 cm^2)

9.4.2 *Test Method* — High-Low Frequency MOS C-V.

9.4.3 If care is taken in their fabrication to minimize oxide surface damage and contamination during silicon etching, good quality quasi-static MOS C-V curves can be measured. From comparison of high and low frequency C-V curves, midgap interface state density can be determined. Details of the test structure and the test method are determined by negotiation between wafer users and wafer suppliers.

9.5 *Doping Density*

9.5.1 *Test Method* — SIMS

9.5.1.1 Be careful of electrical charging up of test pieces due to the existence of BOX, the difference of detecting sensitivity between silicon and silicon dioxide, and the existence of disturbance ions such as $Si^{30}H^{1}$ in case of P^{31} measurement.

Table 9 Relationship Between Wavelength of the Light and Penetration Depth

Wavelength [nm]	450	532	635	670	780	820	850
Depth [μm]	~ 0.8	~ 1.4	~ 3.0	~ 4.0	~ 10.0	~ 14.0	~ 18.0

9.5.2 *Test Method* — Four point probe

9.5.2.1 By contacting the equally spaced four point probes with a wafer and by supplying current between the outer two probes, the voltage difference between the inner two probes is measured. The silicon resistivity ρ is determined by the following equation (JIS H0602):

$$\rho = \pi V/\ln 2 \bullet I \bullet d[\Omega cm] \quad \text{if probe interval} >> \text{top silicon film thickness: d}$$

9.5.3 The specific test method should be determined between wafer users and wafer suppliers.

10 Packing and Marking

10.1 Special packing requirements shall be subject to agreement between the users and the suppliers. Otherwise all wafers shall be handled, inspected, and packed in such a manner as to avoid chipping, scratches and contamination, and in accordance with the best industry practices to provide sample protection against damage during shipment.

10.2 The wafer supplied under these specifications shall be identified by appropriately labeling on the outside of each box or other container and each subdivision thereof in which it may be reasonably expected that the wafers will be stored prior to further processing. Identification marks, codes, symbols and content shall be agreed upon between users and suppliers.

SEMI M42-1000
SPECIFICATION FOR COMPOUND SEMICONDUCTOR EPITAXIAL WAFERS

This specification was technically approved by the Global Compound Semiconductor Committee and is the direct responsibility of the North American Compound Semiconductor Committee. Current edition approved by the North American Regional Standards Committee on August 28, 2000. Initially available at www.semi.org September 2000; to be published October 2000.

1 Purpose

1.1 Compound semiconductor epitaxial layers have been extensively used for many years as the basis of high speed electronics and optoelectronic devices. There are suppliers of epitaxial layers who will grow material to the customer's specification. There is a need to define standardized descriptive terms, tolerance schedules and recommended test methods to reduce ambiguity in the interpretation of specifications for such wafers. Special emphasis is placed on the definitions pertaining to uniformity. This proposed document addresses only the basic requirements. Further clarification may be required between supplier and purchaser for the particular layers required.

2 Scope

2.1 These specifications cover the requirements for epitaxial layers of the generic composition $A_aB_bC_c...N_n$ grown on monocrystalline wafers of GaAs or InP (other substrates may be considered where appropriate documents exist to describe the specification of the substrate). This document may only cover a portion of the properties considered to be part of the purchase specification.

2.2 This specification does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this specification to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Referenced Standards

3.1 *SEMI Standard*

SEMI M1 — Specifications for Polished Monocrystalline Silicon Wafers

3.2 *ASTM Test Methods*[1]

ASTM F76 — Standard Test Methods for Measuring Resistivity and Hall Coefficient and Determining Hall Mobility in Single-Crystal Semiconductors.

ASTM F673 — Standard Test Methods for Measuring Resistivity of Semiconductor Slices or Sheet Resistance of Semiconductor Films with a Noncontact Eddy Current Gage.

3.3 *DIN Standard*[2]

DIN 50447 — Contactless Determination of the Electrical Sheet Resistance of Semiconductor Layers with the Eddy Current Method

4 Terminology

4.1 *epitaxy* — the growth of a single crystal layer on a substrate of the same material, homoepitaxy; or on a substrate of different material with compatible crystal structure, heteroepitaxy

4.2 *fixed quality area (FQA)* — (refer to Figure 1 of SEMI M1) the central area of the wafer surface, defined by a nominal edge exclusion, X, over which the specified values of a parameter apply.

4.3 *mismatch* — the ratio, m_c, defined by the lattice constant of the epitaxial layer perpendicular to the surface, c, minus that of the substrate, a_o divided by the substrate lattice constant.

$m_c = (c - a_o)/a_o$

4.4 *mole fraction* — the normalized fraction of a particular element occupying the same lattice site in a compound. E.g. in the compound $A_aB_bC_cD_d$, a, b, c and d are the mole fractions of the elements A, B, C and D respectively. If, in this example, A and B share the same lattice site, and C and D share the other lattice site, then by definition the sum of a and b, and the sum of c and d each must be 1.

4.5 *graded layer* — a layer whose properties vary smoothly in the direction perpendicular to the surface. The properties of a graded layer are specified in terms of the parameters at the top (last to grow surface) and bottom (first to grow surface) of the layer and unless otherwise specified, are expected to vary linearly between these two end values.

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, PA 19428-2959

2 Deutsches Institut für Normung e.V., available from Beuth Verlag GmbH, Burggrafenstrasse 4-10, D-10787 Berlin, Germany

5 Wafer Ordering Information

5.1 Purchase orders for epitaxial layers must include the following items:

5.1.1 The substrate (as described by the relevant SEMI Standard).

5.1.2 The epitaxy growth method.

5.1.3 The nominal edge exclusion used to define the FQA.

5.1.4 The composition of each layer in terms of mole fraction(s) and a description of the test method used to measure it and/or calibrate the growth conditions of that layer. Note that in the case of a ternary compound, the purchaser may require that the specification for mismatch or bandgap energy take precedence over that for nominal composition. Similarly in the case of a quaternary compound, a specification of mismatch and bandgap energy may be preferred. This is because the mismatch and bandgap energy, which depend on the composition, are often easier to measure than the composition directly.

5.1.5 The thickness of each layer and a description of the test method used to measure it and/or calibrate the growth conditions of that layer.

5.1.6 The dopant used for each layer.

5.1.7 The carrier concentration of each layer and a description of the test method used to measure it and/or calibrate the growth conditions of that layer. In the case of layers with significant interface or surface depletion, the carrier concentration refers to the value that would be observed in thicker layers, once the appropriate correction is applied for interface and surface depletion effects.

5.1.8 *Optional Criteria* — The following items may also be specified in addition to those listed above.

5.1.8.1 The mobility of each layer.

5.1.8.2 The sheet resistance of the epitaxial layers.

5.1.8.3 The mismatch for each layer. The test method must be described.

5.1.8.4 The bandgap energy for each layer. The test method must be described.

5.1.8.5 The sheet carrier concentration and mobility of the whole structure. This is relevant to those structures where the carriers are expected to redistribute to an adjacent material or interface.

5.1.8.6 The surface defect density.

5.1.8.7 The end values and thickness of each graded layer.

5.1.8.8 The surface roughness. The test method must be described.

5.1.8.9 The growth and test methods of a calibration structure along with a schedule for the growth of such a structure.

6 Tolerance Requirements

6.1 The tolerance requirements for the specified parameter, unless otherwise agreed to between the supplier and purchaser, are as in Table 1. Tolerance is defined as the allowed range of values permissible within the FQA and includes variations due to non-uniformity and deviation from the customer's target value. The measurement point schedule (map of measurement points) should be agreed upon between the supplier and purchaser. Three classifications are given for products of varying control needs.

Table 1 Parameter and Tolerance Requirements

Parameter	*Tolerance A*	*Tolerance B*	*Tolerance C*
composition [mole fraction (s)]	± 0.05	± 0.01	± 0.005
thickness [percent of nominal]	± 20%	± 10%	± 5%
carrier concentration [percent of nominal]	± 20%	± 10%	± 5%
sheet resistance [percent of nominal]	± 20%	± 10%	± 5%

Table 2 Parameter and Recommended Measurement Technique

Parameter	*Technique*	*Test Method*
composition	infer from bandgap energy measured by photoluminescence, or photo reflectance and/or from mismatch measured by high resolution X-ray diffractometry	under development none as yet
thickness	cleaved cross sections measured by optical or scanning electron microscopy and/or profilometry of selectively etched layers	needs revision none as yet
carrier concentration	Hall effect or C-V profiling (electrochemical or mercury probe)	ASTM F 76- needs revision none as yet
sheet resistance	Van der Pauw technique and/or eddy current	ASTM F 76 ASTM F 673 or DIN 50447
mobility	Hall effect	ASTM F 76

7 Test Methods

7.1 Measurements shall be carried out according to the methods outlined in Table 2. Where no methods are specified, or where choices are given, the supplier and purchaser shall agree in advance on the means for making the measurement.

7.2 Given the state of development for the recommended test methods and the lack of standard reference materials, it is advisable that the vendor and purchaser exchange samples to cross calibrate their measurement instruments and procedures.

8 Marking

8.1 In addition to the requirements set out in the specification for the substrates, a unique number traceable to the growth run shall be identified on the supplier's certificate.

9 Certification

9.1 Upon request of the purchaser in the contract or order, a manufacturer's or supplier's certification that the material was manufactured and tested in accordance with this specification, together with a report of the test results, shall be furnished at the time of shipment.

9.2 The user and supplier may agree that the material shall be certified as "capable of meeting" certain requirements. In this context, "capable of meeting" shall signify that the supplier is not required to perform the appropriate tests in Section 7; however, if the user performs the test and the material fails to meet the requirement, the material may be subject to rejection.

SEMI M43-0301
GUIDE FOR REPORTING WAFER NANOTOPOGRAPHY

This guide was technically approved by the Global Silicon Wafer Committee and is the direct responsibility of the North American Silicon Wafer Committee. Current edition approved by the North American Regional Standards Committee on November 22, 2000. Initially available at www.semi.org December 2000; to be published March 2001.

1 Purpose

1.1 This guide provides a framework for reporting of nanotopography surface features on silicon wafers.

2 Scope

2.1 This guide addresses reporting the characterization of nanotopography surface features found on wafer surfaces. Nanotopography is the non-planar deviation of the whole front wafer surface within a spatial wavelength range of approximately 0.2 to 20 mm and within the fixed quality area (FQA). Typical examples include dips, bumps or waves on the wafer surface that vary in peak to valley height from a few nanometers to a several hundred nanometers.

2.2 This guide provides a framework for communicating specific values limiting feature levels and/or densities as agreed upon between suppliers and users.

2.2.1 *Discussion* — Nanotopography measurements have not been needed for 0.25 µm generation devices, but are expected to be required for smaller feature sizes to meet CMP requirements. Nanotopography on a wafer surface prior to CMP processes can result in variations in post-CMP dielectric thickness with potential negative consequences for circuit performance and yield; features as small as 20 nm (peak to valley) can result in post CMP discoloration of dielectrics as a result of local thickness variation of the remaining dielectric[1]. Height variations over specified distances (determined by CMP issues and/or lithography systems) need to be properly controlled to assure that wafers are acceptable for selected process steps. In the case of CMP, the issue is control of film thickness variation introduced by nanotopography. The metrology industry is building tools that will measure and map surface features at nanotopography amplitudes and spatial wavelengths. Nanotopography features are characterized by their height variation within an area, and are discriminated from other features of similar height by their spatial wavelength range.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety health practices and determine the applicability or regulatory limitations prior to use.

3 Limitations

3.1 The reported surface features will be influenced by limitations and parameters of the measurement tool. These include:

3.1.1 The finite surface spatial bandwidth of the tool and the applied filtering will prevent surface variations outside the bandwidth of operation from being measured. Also, the finite bandwidth of filtering produces non-physical artifacts that may be apparent in regions where the power in the rejected bands is high.

3.1.2 Bandwidth edges are not always well defined. Measurement results do not always agree well between systems, because different tool designs employ different geometries and operate them over different spatial bandwidths.

3.1.3 All surface profiling measurement systems have a minimum height variation sensitivity that will distort signals near the noise floor.

3.1.4 The reported shape of some features may also depend on the pixel grid orientation employed by the instrument.

3.1.5 The pixel size and sampled area will affect the bandwidth limits.

3.2 Reported profiles also vary with interactions between wafer and tool. These limitations include:

3.2.1 Measurements made near the wafer edge may result in false readings. Under certain conditions, this may cause incorrect height measurement within the FQA.

3.2.2 Closely spaced features may be counted as a single feature, or as no feature, if the pixel size is larger than the feature, or is larger than the spacing between features. Reported features may result from the combination of the actual surface features, the manner in which the wafer is chucked, or be caused by particles trapped between the wafer back surface and the chuck.

3.2.3 High-pass (spatial frequency) filtering is typically used with these measurements to remove the (long-spatial wavelength) effects of wafer shape (such

1 K. V. Ravi, "Wafer Flatness Requirements for Future Technologies," Future Fab International, July 1999.

as bow, warp and sori). This filtering may affect the reported results.

3.3 Nanotopography characterization does not include microroughness, which applies to a shorter spatial wavelength range.

3.4 The location of defective areas as calculated in section 6 may not coincide with the location of the surface features that lead to those values. This may cause lack of spatial correlation between reported defective areas and device process defect areas.

3.5 The height map used to create nanotopography reports may be affected by wafer shape and measurement chuck effects.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI M1 — Specification for Monocrystalline Polished Silicon Wafers

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 *fixed quality area (FQA)* [SEMI M1] — the central area of a wafer surface, defined by a nominal edge exclusion, X over which the specified values of a parameter apply.

Discussion: The boundary of the FQA is at all points the distance X away from the periphery of a wafer of nominal dimensions. (See Figure 1). The size of the FQA is independent of the wafer diameter and flat length tolerances. For the purpose of defining the FQA, the wafer periphery at locations with notch fiducials is assumed to follow the circumference of a circle with diameter equal to the nominal wafer diameter.

5.2 *nanotopography, of a wafer surface* — the non-planar deviation of a surface within a spatial wavelength range of approximately 0.2 to 20 mm.

5.3 *nanotopology, of a wafer surface* — see *nanotopography*.

5.4 *roughness* [SEMI M1] — the more narrowly spaced components of surface texture.

Discussion: These components are considered within defined limits of spatial wavelength (or frequency).

5.5 *spatial wavelength* — the spacing between adjacent peaks of a purely sinusoidal profile.

6 Measurements

6.1 The height map is obtained from a front-surface measurement. An explicit reference plane is not used for calculating and assigning values.

NOTE 2: Other methods of analyzing nanotopography may require the use of an explicit reference plane.

6.2 The high-pass filter removes long spatial wavelength wafer tilt and topography effects, effectively creating a global reference surface.

6.3 *Calculation* — The calculation determines the peak to valley height (P-V) variation among the pixels included in the analysis area, and assigns that variation in nanometers to the center of the analysis area. The calculation is performed for every analysis area within the FQA of the wafer. These calculations may be repeated for analysis areas of different dimension D.

NOTE 3: This calculation describes the "full-analysis area" method. There is another calculation, the "partial analysis area" method, where the calculation is performed for every analysis area whose center pixel is within the FQA of the wafer. The partial analysis area method, not defined in this document, is being addressed by SEMI for inclusion in a standard.

6.4 The following measurement elements should be reported:

6.4.1 *Filtering*

a) Spatial cutoff of high pass filter

b) Type of Filter

c) Pixel spacing

Filtering is used to remove long wavelength shape components from the raw height data.

6.4.2 *Analysis Area* — Specify this analysis area's:

a) Shape, e.g., square, circle, and

b) Dimension *D* of the analysis area

An analysis area contains a pixel at its center (Figure 1). The pixels within the surrounding analysis area of dimension *D*, and within the FQA, are used to determine the value assigned to the center pixel location.

6.4.3 *Data Report* — Report one or more of the following:

6.4.3.1 *Statistical Representation by Threshold Curve* — Plot, for each D, % area vs. threshold T, in nanometers, where % area is the ratio of

a) the number of analysis areas whose assigned value (calculated per Section 6.3) exceeds the threshold T, to

b) the number of pixels within the FQA.

The ratio is expressed as a percentage.

6.4.3.2 *Tabular Representation by % Area Sorted* — Specify a threshold T for each D and report the % area.

6.4.3.3 *Tabular Representation by Threshold* — Specify a % area for each D and report the Threshold, T.

6.4.3.4 *Spatial Representation by Height Map* — Generate a whole wafer height map of the surface.

6.4.3.5 *Spatial Representation by Defect Map* — Generate a whole wafer height map of the surface. Analysis areas whose assigned values (calculated per Section 6.3) exceed the threshold in Section 6.4.3.2 are flagged for each D.

6.4.3.6 *Spatial Representation by PV Analysis Map* — Generate a whole wafer map of the values assigned in Section 6.3.

SEMI M44-0702
GUIDE TO CONVERSION FACTORS FOR INTERSTITIAL OXYGEN IN SILICON

This guide was technically approved by the Global Silicon Wafer Committee and is the direct responsibility of the North American Silicon Wafer Committee. Current edition approved by the North American Regional Standards Committee on April 30, 2002. Initially available at www.semi.org June 2002; to be published July 2002. Originally published March 2001.

1 Purpose

1.1 This guide is a compilation of the conversion and calibration factors used by different standards established for the measurement of interstitial oxygen in silicon.

2 Scope

2.1 This guide allows the user of the guide to convert quantitative values obtained from one standard to another.

2.2 This guide does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this guide to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Referenced Standards

NOTE 1: Unless otherwise indicated, all documents cited shall be the latest published versions.

3.1 *SEMI Standards*

SEMI M1 — Specifications for Polished Monocrystalline Silicon Wafers

SEMI M11 — Specifications for Silicon Epitaxial Wafers for Integrated Circuit (IC) Applications

3.2 *ASTM Standards* [1]

F121-79 — Test Method for Interstitial Atomic Oxygen Content of Silicon by Infrared Absorption

F121-83 — Test Method for Interstitial Atomic Oxygen Content of Silicon by Infrared Absorption

F1188 — Test Method for Interstitial Atomic Oxygen Content of Silicon by Infrared Absorption (refers to IOC-88[2])

F1241 — Standard Terminology of Silicon Technology

3.3 *DIN Standard* [3]

DIN 50438-1[1994, 1995] — Determination of Impurity Content in Silicon by Infrared Absorption; Part 1 Oxygen[4] (refers to IOC-88[2])

DIN 50438 Part 1 [1978] — Determination of Impurity Content in Silicon by Infrared Absorption: Oxygen

3.4 *JEITA Standard* [5]

JEIDA 61 — Standard Test Method for Atomic Oxygen Content of Silicon by Infrared Absorption (refers to IOC-88[2])

4 Terminology

4.1 Many terms relating to silicon technology are defined in ASTM Terminology F 1241.

5 Other Techniques

5.1 Other measurement techniques for measuring oxygen in silicon (e.g., SIMS or GFA) measure total oxygen whereas the referenced methods measure interstitial oxygen only. For details, refer to Volume 10.05 of *Annual Book of ASTM Standards*.

6 Conversion Factors Among International Standards

6.1 Table 1 gives the conversion factors to convert oxygen concentration of one standard to oxygen concentration of another standard.

6.2 Table 2 gives the calibration factors to relate peak absorption coefficient (cm^{-1}) to interstitial oxygen content in both parts per million atomic (ppma) and $atoms/cm^3$ for various standards that have been replaced by newer revisions.

SEMI M45-0301
PROVISIONAL STANDARD FOR 300 mm WAFER SHIPPING SYSTEM

This standard was technically approved by the Global Silicon Wafer Committee and is the direct responsibility of the Japanese Silicon Wafer Committee. Current edition approved by the Japanese Regional Standards Committee on December 1, 2000. Initially available at www.semi.org January 2001; to be published March 2001.

1 Purpose

1.1 This standard stipulates transport related materials and systems to minimize the total cost relating to transport of 300 mm wafers from the wafer supplier to the customer.

2 Scope

2.1 This standard stipulates materials relating to transport of 300 mm wafers using Shipping Boxes (FOSB) regulated by SEMI M31, and includes wafer shipping boxes, bags, labels, cushions, secondary containers, pallets, and shipping documentation.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety health practices and determine the applicability or regulatory limitations prior to use.

NOTE 1: This standard is provisional because some technical issues are not implemented. Once these issues are addressed, this standard should be modified and upgraded from provisional status.

3 Referenced Standards

NOTE 2: As listed or revised, all documents cited shall be the latest publications of adopted standards.

3.1 *SEMI Standards*

SEMI M31 — Provisional Mechanical Specifications for Front-Opening Shipping Box Used to Transport and Ship 300 mm Wafers

SEMI T3 — Specification for Wafer Box Labels

3.2 *ANSI Standards*

ASNI/EAI-556-B — Outer Shipping Container Label Standard[1]

4 Terminology

4.1 *bag* — a package used for sealing the outside of the wafer shipping box. Typically two or three types of different plastic film and aluminum film are laminated, and these are usually heat-sealed.

4.2 *cushions* — materials placed between the wafer shipping box and secondary container in order to absorb shock during shipping and to stabilize the wafer shipping box within the secondary container.

4.3 *label* — the label on the wafer shipping box or items such as bags identifying the product and its manufacturer.

4.4 *pallet* — a flat container used for collecting and holding a suitable amount of secondary containers that hold wafers, to make handling with forklifts easier.

4.5 *recycle* — to use an already used item for some other useful purpose.

4.6 *reuse* — to repeat use of an item in its original shape for the same purpose as initially intended.

4.7 *secondary container* — the outermost box of the smallest transport unit. Typically cardboard boxes or similar boxes are used.

4.8 *shipping document* — documents required when shipping.

4.9 *wafer shipping box* — a box that directly holds the wafers. In this standard, this box is specified by SEMI M31.

5 Requirements

5.1 *Wafer Shipping Box*

5.1.1 Wafer shipping boxes that comply with SEMI M31 must be used.

5.1.2 There are no grounding or ESD requirements for wafer shipping box.

5.1.3 To make sure raw materials are traceable, the product number, revision number, and manufacturing period (year, week) must be displayed on the wafer shipping box main device and door by molding or by a method that cannot be easily erased.

5.1.4 The wafer shipping box door must be designed so that it can be automatically as well as manually opened and closed.

5.1.5 Optional top robotic handling flange or side mounted human handles will not be attached during transport of the wafer shipping box. If required, these items will be applied at the receiving site. The design of

1 Available from Global Engineering Documents, 15 Inverness Way East, Englewood, CO 80112-5704.

these features will allow for quick, lockable attachment to the wafer shipping box.

5.1.6 Wafers must be visible inside when the wafer shipping box is closed.

5.1.7 No tape may be used to seal the wafer shipping box.

5.1.8 The only environment in which wafers can be placed into or taken out of a wafer shipping box bag, as well as the surrounding environment thereafter, is clean room air.

5.1.9 The body and door of the wafer shipping box must be designed to allow for multiple reuse cycles without compromising wafer quality.

5.1.10 After a customer has transferred an accepted wafer to a fab carrier, the wafer shipping box must be returned to the supplier without having used it for any other purpose. The wafer shipping box will be inserted into a bag sealed prior to return to the wafer supplier using the same type bag (agreed upon by supplier and customer).

5.1.11 Each wafer shipping box must be returned only to the supplier that delivered the wafers for which the wafer shipping box was used. A display for the supplier showing the number of times a wafer shipping box was used is optional.

5.1.12 The property rights of wafer shipping box used to deliver wafers and to be returned after unloading belong to the wafer manufacturers.

5.1.13 The wafer shipping box will maintain its dimensional stability throughout its lifetime.

5.1.14 Wafer shipping box materials must be recyclable after useful life.

5.2 *Wafer Shipping Box Bagging System*

5.2.1 It is preferable that the bag material is recyclable, but until a technical solution is found, bags should be easily disposable.

5.2.2 The bagging system must consist of two or more layers of bags. At least one layer must be a moisture barrier.

5.2.3 The use of desiccant between the bag layers is currently optional. Its use must not negatively impact the cleanliness of the bagging system.

5.2.4 Bags may be evacuated optionally. The initial bag ambient, prior to evacuation and sealing, may be temperature/humidity controlled clean room air, clean dry air (CDA), or nitrogen (N2).

5.3 *Wafer Shipping Box and Bag Labeling*

5.3.1 Prepare and apply two identical labels that are in accordance with SEMI T3, with additional requirements as noted below.

5.3.1.1 Label size may be as large as 120 mm x 120 mm.

5.3.1.2 Label data content shall include all the data specified in SEMI T3, including wafer ID and FOSB slot #. Additional data may be added optionally, as agreed to between supplier and user.

5.3.1.3 Apply one label to the center of the rear surface of the FOSB. The long axis of the label shall be parallel to the FOSB base.

5.3.1.4 Apply the other label to the shipping bag, on the door side of the FOSB.

5.3.2 The wafer shipping box and outer bag labels should use the same peelable, cleanroom compatible label stock. The labels must not leave residual adhesive or backing material on the wafer shipping box when removed.

5.4 *Secondary Container Labeling*

5.4.1 Labels shall be placed in accordance with EIA-556-B.

5.4.2 Prepare labels in accordance with EIA-556-B. Information shall include at least the following [Items below marked by an asterisk (*) are mandatory EIA-556-B data fields]:

5.4.2.1 *Bar Code Data Fields*

- Transport unit License Plate number*
- Transaction identification (Purchase Order number)*
- Total Quantity of Wafers*
- Total Quantity of Cartons
- Customer Part number*

5.4.2.2 *Non-Bar Code Data Fields*

- Ship-to address (including Customer name)*
- Ship-from address (including Supplier name)*

5.4.2.3 Optional information, as agreed to between supplier and user, may be included.

5.5 *Secondary Container*

5.5.1 Whether the secondary container material is a single use material or a material that can be reused multiple times should be decided by considering the transport environment to minimize the packaging cost.

The same is true for the secondary container sealing system.

5.5.2 The secondary container should be collapsible for efficient storage and empty transport.

5.5.3 The materials for the secondary container should be recyclable after the designated number of uses is completed.

5.5.4 The design and size of the secondary container should have an optimal fit with the standard pallet noted in Section 5.7.2, and should have the strength to be stacked in four layers.

5.5.5 The number of wafer shipping boxes per secondary container must allow for optimal transportation costs.

5.5.6 Ergonomic considerations should be made for the secondary container, and should be compatible with manual handling. When handling very large quantities, a supplemental handling system is necessary.

5.5.7 The secondary container design is not required to provide specific weather protection. The storage environment should not be affected by the weather.

5.6 *Cushions*

5.6.1 Whether the cushion material is a single use material or a material that can be reused multiple times should be decided by considering the transport environment to minimize the packaging cost.

5.6.2 For the sake of efficiency during holding and transport, it is preferable to have only one or two cushions per secondary container.

5.6.3 The materials for the cushions should be recyclable after the designated number of uses is completed.

5.7 *Pallet*

5.7.1 Pallets must be stand-alone components and are not integrated with secondary containers.

5.7.2 Considering space efficiency of ocean freight containers, it is preferable that the pallet size be 1130 mm max on at least one side.

5.7.3 Palletized containers must be banded and film-wrapped.

5.7.4 Pallet material must meet transportation industry requirements and allow for reuse and recycle after end of useful life.

5.7.5 Pallets must be able to be accessed by a forklift from at least two directions.

5.8 *Shipment Documentation*

5.8.1 English should be used for all international shipment documentation. The local language may be used only for domestic shipments only.

5.8.2 Packing list and customs invoice (if required) should be located on the outside of container number 1 with a sufficient number of copies to ensure the customer receives one copy.

5.8.3 Customs invoices must meet appropriate government regulations. Key content items are: PO number, product description, price, shipping address, and cross-reference to packing list.

5.8.4 The packing list must contain: date, customer shipping address, supplier name, country of origin, PO number, customer part number, shipment quantity, total number of cartons, carton identifiers.

5.8.5 The certificate of analysis or conformance should be electronically transmitted from wafer supplier to customer. Electronic transmission format must be flexible to allow for future content changes.

5.9 *Transportation Logistics*

5.9.1 Small quantity shipments or expedited shipments may require a special secondary container size.

5.9.2 The 300 mm wafer shipping system design must comprehend both surface and air transportation.

APPENDIX 1

NOTE: This appendix was approved as an official part of SEMI M45 by full letter ballot procedure, but the recommendations in this appendix are optional and are not required to conform to this standard.

A1-1.1 The 300 mm Wafer shipping box must be re-usable in view of the wafer manufacturing cost and environmental concerns.

A1-1.2 When the shipping box is re-used, the customer who received wafers must keep the shipping box in good condition after opening the package and return to the wafer supplier.

A1-1.3 The box cleaning process of the supplier can not remove ink, adhesive, and excessive metal contamination of the returned shipping box.

A1-1.4 The customers must avoid contaminating the shipping boxes in this way. The customers must keep the shipping box separate from those contaminated conditions. Contaminated shipping boxes must not be returned to the supplier.

SEMI M46-1101^{E}
TEST METHOD FOR MEASURING CARRIER CONCENTRATIONS IN EPITAXIAL LAYER STRUCTURES BY ECV PROFILING

This test method was technically approved by the Global Compound Semiconductor Committee and is the direct responsibility of the European Compound Semiconductor Materials Committee. Current edition approved by the European Regional Standards Committee on June 29, 2001. Initially available at www.semi.org December 2001; to be published March 2002.

^{E} This document was editorially modified in November 2001 to correct a typographical error. A change was made to Section 7.3.3.

1 Purpose

1.1 The purpose of this document is to specify a method to measure the carrier concentration and carrier concentration vs. depth profile of epitaxial layers by Electrochemical Capacitance Voltage ECV profiling.

2 Scope

2.1 This test method covers a procedure for measuring the carrier concentration of epitaxial layers by ECV profiling. This method focuses on improving the accuracy and repeatability of the measurement by standardizing the test conditions and reporting and by routine calibration of the measurement.

2.2 This test method is intended to cover the majority of routine samples measured. However, because of the number of different materials encountered it cannot cover every contingency.

2.3 This standard may involve hazardous materials. This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Referenced Standards

3.1 *SEMI Standards*

SEMI C1 — Specifications for Reagents

3.2 *ASTM Standards*

D1125-95 (1999) — Standard Test Methods for Electrical Conductivity and Resistivity of Water

4 Terminology

4.1 *bias* — the potential applied to the sample with respect to a reference electrode.

4.2 *capacitance voltage CV measurements* — electrical measurements where the capacitance of a rectifying barrier is measured as a function of applied bias and is a measure of the net fixed ionized charge per unit volume.

4.3 *carrier concentration* — the net fixed ionized charge per unit volume. Equal to the free carrier concentration if the dopant is fully ionized and the material is free of traps.

4.4 *current voltage IV measurements* — electrical measurements where the current through the rectifying barrier is measured as a function of applied bias.

4.5 *dissipation factor* — the ratio of the real part to the imaginary part of the complex admittance. It is a measure of the non-ideality of the barrier.

4.6 *electrochemical* — chemical reaction in which charge transfer takes place via an external circuit.

4.7 *epitaxial layer* — a layer of single crystal semiconductor material grown on a host substrate which determines its orientation.

4.8 *excess area* — the difference between the wetted and illuminated areas.

4.9 *flatband potential* — the intercept on the voltage axis of the $1/C^2$ vs V plot. A measure of the built in field or barrier height.

4.10 *illuminated area* — the area of the sample which can be illuminated during electrochemical etching.

4.11 *rectifying barrier* — a potential gradient formed at the junction between two materials which permits the flow of charge in one direction only.

4.12 *reference electrode* — half cell which has a constant electrode potential, such as a saturated calomel electrode, SCE.

4.13 *rest potential* — the open circuit potential of the sample with respect to the reference electrode.

4.14 *wetted area* — the area of contact between the electrolyte and the sample.

5 Summary of Method

5.1 In this method, the carrier concentration of the epitaxial layer is measured by the CV method.

5.1.1 Ohmic contacts are formed on the sample.

5.1.2 A rectifying barrier, of known contact area, is formed by placing the sample in contact with an electrolyte.

5.1.3 The quality of the barrier is assessed using I-V and C-V measurements.

5.1.4 From the measured C-V data the carrier concentration of the layer is determined.

5.1.5 The sample is anodically etched to produce a new barrier deeper in the material. The etch depth is determined using Faraday's law of electrolysis.

5.1.6 Sections 5.1.4 and 5.1.5 are repeated to generate a carrier concentration vs. depth profile.

6 Interferences

6.1 *Thin Layers* — Diffusion of carriers into adjacent regions set a fundamental resolution limit to the measurement. In addition if the layer has a high sheet resistivity this can also affect the value obtained.

6.2 Double Layer Capacitance — A limitation imposed by the physical nature of the electrolyte/semiconductor barrier which sets an upper limit to the measured carrier concentration, for accurate measurements, of 1×10^{19} cm^{-3}. The technique can be used beyond this value, but with progressive degradation.

6.3 *Etch Well Uniformity*

6.3.1 *Etch Well Flatness* — Non-uniformity increases the effective area and may result in the measurement not being wholly made in the layer of interest. The main causes of non-uniformity are gas bubbles, inadequate electrolyte circulation and uneven illumination.

6.3.2 *Etch Well Roughness* — indicates poor etching and has a deleterious effect on the measurements. Generally overcome by selecting a more appropriate electrolyte and/or etching conditions.

6.4 *Non-Ideal Electrical Characteristics*

6.4.1 *Series Resistance* — From the contacts, sample and electrolyte affect the accuracy of the measurements. This effect is minimized by using a highly conductive electrolyte, making large area ohmic contacts and by employing a low measurement frequency.

6.4.2 *Leakage Currents* — Parallel conduction can affect the accuracy of the measurement. Its influence is reduced by employing a high measurement frequency.

6.4.3 *Large Excess Area* — Can give rise to errors on n-type material particularly when profiling Hi-Lo structures. The excess area is electrolyte dependent but is mainly affected by the quality of the seal used to define the area. Large excess areas indicate a poor seal and are corrected by replacing the seal.

6.5 *Hi-Lo Structures* — Measurement is subject to inaccuracy due to carrier diffusion and excess area errors. For accurate measurements, chemically etch to the layer of interest before measurement.

6.6 *Contact Quality* — Non-Ohmic or high resistance contacts have a deleterious effect on the measurement. Contacts should be checked by measuring the resistance between two similar contacts and then reversing the current direction and repeating the measurement.

6.7 *Surface and Deep States* — Cause the measured capacitance to be frequency dependent and/or dependent on the rate at which the bias is changed. Usually resolved by using a high measurement frequency. This should not be confused with the frequency dependence which is more usually attributed to high series resistance.

6.8 *Surface Films* — Have a deleterious effect on the capacitance measurement. Film formation should be avoided by using an appropriate electrolyte, control of the etching bias and time and by electrolyte circulation.

6.9 Surface Roughness — The surface of the sample should be smooth and free of features that would affect the action of the seal.

6.10 *Light* — Light can affect the capacitance measurement, so the sample must be placed in a dark environment during the measurement.

6.11 *Sample Loading* — The accuracy of the measurement depends on the repeatability of the area. If a compliant seal is involved, such as a plastic ring, the sample should be held in contact with the seal by applying a controlled and constant force. No relative lateral movement should take place during the loading process.

6.12 *Ring Variability* — The condition of the ring has a large effect on the measurement. Good seals will have a small to zero excess area and exhibit a well defined and reproducible contact area.

7 Apparatus

7.1 *Measurement of Etch Well and Ring Areas* — Measuring microscope with either an XY stage, with a linear resolution of 0.01 mm or better, or a camera and image processing system capable of measuring an area of 0.1 cm^2 to better than 0.5%.

7.2 *Measurement of Etch Well Flatness* — (Optional) A means such as a stylus profiler for checking the flatness and roughness of the etch well. In most cases visual inspection of the etch well, for a mirror like appearance, is sufficient indication of low roughness.

7.3 *Instrumentation*

7.3.1 *Capacitance Meter* — Capable of measuring values up to 300 nF, employing a test signal of amplitude less than 100 mV RMS. The measurement frequency should be typically between 1 and 100 kHz.

7.3.2 *Equivalent Circuit Model* — The meter should assume a parallel circuit model for the electrolyte/semiconductor interface and provision should be made to compensate for the large series resistance of the electrolyte and contacts.

7.3.3 *Potentiostat* — Capable of maintaining the potential of the sample with respect to a reference electrode constant to ±5mV during the measurement and with a reference input impedance of > 10^{13} Ohms.

7.3.4 *Light Source* — A source of uniform illumination of above band gap energy for etching n-type materials.

7.4 *Sample Holder*

7.4.1 *Electrochemical Cell* — Used to hold the sample, contain the electrolyte and support the sealing ring and other electrodes, see Figure 1.

7.4.1.1 *Sealing Ring* — A corrosion resistant ring which forms a seal between the electrolyte and the sample. This ring defines the measurement area which should be reproducible and well defined. The ring area should not be less than 0.008 cm^2 and the reproducibility between runs should be better than ± 3%. Large ring areas (typically ≥ 0.1 cm^2) are preferred for more accurate measurements.

7.4.1.2 *Reference Electrode* — Used to control the sample bias via a potentiostat.

7.4.1.3 *Counter Electrode* — The bias and test signals are applied between this electrode and the sample.

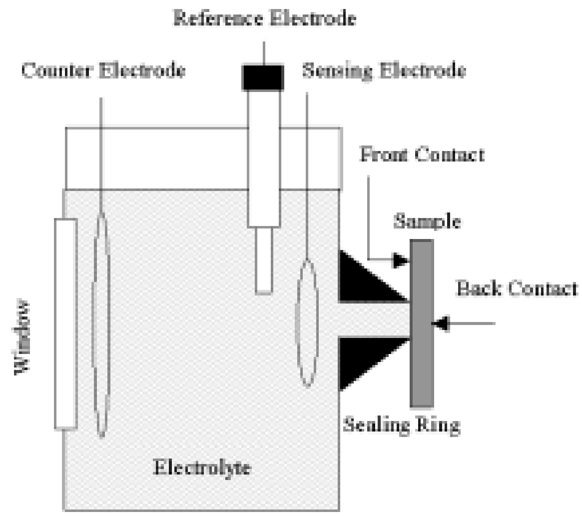

Figure 1
Electrochemical Cell

7.4.1.4 *Sensing Electrode* — Placed close to the sample-electrolyte interface and used to measure the admittance of the sample.

7.4.1.5 *Sample Contacts* — Ohmic contacts to the front and/or back surface of the sample for the purpose of applying bias.

8 Reagents and Materials

8.1 *Purity of Reagents* — All chemicals for which such specifications exist shall conform to SEMI C1.

8.2 *Purity of Water* — Use either distilled or de-ionized water having a resistivity greater than 2 MOhm•cm at 25°C as determined by the Non-Referee Test of Test Methods D 1125.

8.3 *Selection of Electrolyte* — The choice of electrolyte is not defined by this standard and is up to the discretion of the user or by agreement between the customer and the supplier.

8.3.1 *InP, GaAs and Related Compounds* — Preferred electrolyte, Na_2.EDTA (0.1 M) basified with ethylenediamine to a pH of 10, although other electrolytes can be satisfactorily used.

NOTE 1: Preferred electrolyte, see reference “Electrochemical C-V Profiling of Heterojunction Device Structures” A.C.Seabaugh et al. IEEE Trans on Electron Dev 36 No 2 (1989) 309-313.

9 Safety Precautions

9.1 The electrolytes used are potentially hazardous. Read the Materials Safety Data Sheets before attempting to prepare the electrolytes. Use safety eyewear, rubber gloves and protective clothing. Prepare all electrolytes in a fume hood.

9.2 Ensure that all electrolytes are correctly labeled.

10 Specimen Preparation

10.1 The sample should be free from surface debris and scratches. The sample should be cleaned with deionized (DI) water and dried.

10.2 To measure a single layer or upper layer of a multilayered structure, no additional sample preparation is required.

10.3 For a buried layer in a multilayered structure, measurement accuracy is improved by removing the overlaying layers by either the use of selective or controlled chemical etches.

10.4 If the upper layers cannot be removed by chemical etching then the sample can be profiled electrochemically but in some cases this may reduce the accuracy of the method.

10.5 For conducting substrates Ohmic contacts should be made to either the front or back of the wafer. For insulating substrates an Ohmic contact should be made to the front of the epilayer. Contacts are formed electrically, by alloying or by any other suitable method. The quality of the contact should be verified electrically.

11 Calibration and Standardization

11.1 *Sealing Ring* — Calibration of the sealing ring areas is performed using a "blue slice", made by growing an anodic oxide film on a polished n-type substrate.

11.1.1 The "blue slice" is profiled according to this test method. Etch only the minimum amount necessary to see the illuminated area (typically 0.5 μm). Flush the cell several times with DI water before removing the sample. Wash and measure the sample as soon as possible.

11.1.2 *Wetted Area* — The wetted area is observed due to chemical attack of the oxide film and is measured using a measuring microscope with cross hair eye-pieces and micrometer XY stage or by using a zoom camera and image processing system.

11.1.3 *Illuminated Area* — Etches in the light and forms a well defined etch well, which is measured as per the wetted area.

11.1.4 *Calibration Interval* — Regularly check the area and condition of the sealing ring. For daily use, the ring areas should be calibrated at least three times a week.

11.1.5 *Replacement* — Rings should be replaced if the excess area exceeds 10% for rings of area ≤ 0.05 cm^2 or 5% for rings of area > 0.05 cm^2 or if the perimeter is not uniform.

11.1.6 *Alternative Calibration Method* — The areas can be measured using known n and p-type test samples. This method is best suited for continual monitoring of the ring area between "blue slice" calibrations.

11.2 *Instrumentation* — The bias voltage, measurement frequency and capacitance measurement should be checked annually.

11.2.1 *Bias* — The bias voltage should be checked with a DVM with an input impedance > 1 MOhm.

11.2.2 *Capacitance* — The capacitance measurement should be checked using calibrated fixed value capacitors covering the expected sample capacitance range or from 1–100 nF.

11.2.3 *Frequency* — The measurement frequency should be checked with a frequency counter.

12 Measurement Procedure

12.1 *Choice of Electrolyte* — An electrolyte should be selected that forms a rectifying barrier with the sample, gives a flat, mirror finish etch well and generates only a small excess area.

12.2 *Sample Mounting* — A region of the sample should be defined which will form the rectifying contact with the electrolyte. This area can be defined by some form of sealing ring or mask, but it is important that the area of contact between the electrolyte and the sample be precisely known and remain constant during the measurement.

12.2.1 *Sealing Ring* — If the sample is pressed against a sealing ring, the seal must be cleaned with DI water and dried before positioning the sample. If the sample needs repositioning, the sample and sealing ring should be recleaned and dried.

12.2.2 *Ring Loading* — As the mounting pressure may effect the reproducibility of the measurement and the lifetime of the sealing ring, it must be controlled (e.g. by the reproducible use of a suitable compression spring).

12.3 *Cell Filling and Debubbling* — Fill the cell, which holds the sealing ring and other measurement electrodes, with the electrolyte. The process of filling the cell frequently traps bubbles of air on the surface of the sample. These bubbles must be removed before a measurement can be made.

12.4 *Contact Evaluation* — Verify that the contacts, for both directions of current flow have low and approximately equal resistance.

12.5 *Rest Potential* — Measure the sample's rest potential to verify that the reference electrode and sample are electrochemically stable. Its value usually lies between 0 and −1 V (respective to a SCE reference electrode). Values outside this range can indicate a problem with the sample or reference electrode.

12.6 *Cable Compensation* — Determine any stray capacitance or additional resistance associated with the cell and test leads that would impact the measurement.

12.7 *Current vs. Voltage (I-V)* — Used to select the bias for measurement and etching and as a general test of material quality.

12.7.1 *Measurement Bias* — is set in the reverse bias, low dark current region.

12.7.2 *Etching Bias (p-type material)* — is set in the forward bias region. The abruptness of the forward bias breakdown is indicative of the ohmic nature of the contacts. No or shallow forward breakdown often indicates unsuitable ohmic contacts.

12.7.3 *Etching Bias (n-type material)* — is set in the reverse bias, low dark current region. Illumination should result in a significant increase in current (photo-current).

12.8 *Capacitance vs. Voltage (C-V)* — Used to evaluate the quality of the electrochemical diode and to select a range of possible measurement voltages. The measured flatband potential (respective to a SCE reference electrode) should lie between −0.5 and −2.5 V for n-type semiconductors and between –1 and +1 V for p-type semiconductors.

12.8.1 *Measurement Bias* — is set in a region of low dissipation, where the $1/C^2$ vs V plot is linear. For layers grown with concentration gradients, the latter condition cannot be strictly adhered to and in such cases the amplitude of the test signal, used for capacitance measurement, should be kept as small as possible.

12.8.2 *Dissipation* — The normally accepted safe level is < 0.4.

12.8.3 *Excess Area Capacitance* — For n-type surface layers the capacitance of the electrolyte/semiconductor interface is measured prior to etching and the capacitance associated with the excess area is computed by multiplying the measured capacitance by the ratio of the excess area to the wetted area.

12.9 *Carrier Concentration Profiling* — Profile the sample using the etching and measurement conditions determined from the I-V and C-V data.

12.9.1 *Carrier Concentration* — The carrier concentration is determined from the C-V data.

12.9.2 *Excess Area Correction* — For n-type material the capacitance associated with material in the excess area should be subtracted from the measured capacitance.

12.9.3 *Etching* — The sample is anodically etched at the etching bias. The depth of the etch well is determined from the time integral of the current using Faraday's law of electrolysis.

12.9.4 *Profiled Depth* — The profile assumes that the measured carrier concentration lies at a depth equal to the sum of the etch and the depletion depths.

12.10 *Ring Area* — It is advised to measure the etch well area after profiling and to use this value to recalculate the carrier concentration vs. depth profile.

13 Calculations and Interpretation of Results

13.1 *Carrier Concentration,* N

The principle of this method is based on measuring the slope of $1/C^2$ vs V.

$$N = \frac{-2}{q\varepsilon_0\varepsilon_r A^2}\cdot\left[\frac{d\left(1/C^2\right)}{dV}\right]^{-1} \qquad [\mathrm{cm}^{-3}]$$

where

C is the measured capacitance (for n-type material the capacitance associated with the excess area should be subtracted from the measured capacitance),
V is the applied bias,
q is the electronic charge,
ε_r is the relative permittivity of the sample,
ε_o is the permittivity of free space
(= 8.854×10^{-12} Fm^{-1})
A is the area of the etch well

It is also possible to measure dC/dV by modulating the bias with a low frequency (secondary signal). The $d(1/C^2)/dV$ of the upper equation may be evaluated to result in the following formula.

$$N = \frac{1}{q\varepsilon_0\varepsilon_r A^2}\cdot\frac{C^3}{dC/dV} \qquad [\mathrm{cm}^{-3}]$$

13.1.1 *Excess Area Capacitance*, C_{excess}

$$C_{excess} = C.\frac{A_w - A_i}{A_w} \qquad [F]$$

Where

C_{excess} is the capacitance of material in the excess area,

A_w is the wetted area,

A_i is the illuminated area

13.2 *Depletion Depth*, W_d, — calculated from the parallel plate capacitor equation.

$$W_d = \frac{\varepsilon_0 \varepsilon_r A}{C} \qquad [\mu m]$$

13.3 *Etched depth*, W_e, — calculated from the charged passed through the cell using Faraday's law for electrolysis.

$$W_e = \frac{M}{zFDA} \int I dt \qquad [\mu m]$$

Where

z is the effective dissolution valency,
F is the Faraday constant,
(= 9.65×10^4 $Cmol^{-1}$)
D is the density of the semiconductor,
M is the molecular weight of the semiconductor
I is the etch current

13.4 *Total depth*, W, — the sum of the depletion and etch depths and is the depth at which the measurement is made.

$$W = W_d + W_e \qquad [\mu m]$$

14 Reporting Results

14.1 The following information shall be included in the report:

14.1.1 *Identification of Specimen* — including details of any pretreatment such as the use of a selective etch to chemically etch the sample to the layer of interest.

14.1.2 *Sealing Ring Area* — both the wetted and illuminated areas should be reported.

14.1.3 *Electrolyte* — the composition of the electrolyte should specify the molecular concentration.

14.1.4 *Material Constants* — The relative permittivity of the sample, ε_r and the effective dissolution valency, z.

14.1.5 *Primary Measurement Signal* — the frequency and amplitude of the signal used for the capacitance measurement.

14.1.6 *Secondary (bias) Signal* — If the measurement is made using a secondary modulation component its frequency and amplitude should be reported. If the measurement is made by changing the bias, its minimum and maximum value should be specified.

14.1.7 *Measurement Bias* — The average value (DC component) of the bias used during the capacitance measurement.

14.1.8 *Electrochemical Etching Bias* — The bias used to etch the sample including whether or not the sample was illuminated. If etched at a constant current this should be stated. Then it is not necessary to report the bias.

14.1.9 *Electrochemical Etching Current* — If etched at constant bias the average value of current measured during electrochemical etching. If etched at a constant current the value used.

SEMI M47-0302
SPECIFICATION FOR SILICON-ON-INSULATOR (SOI) WAFERS FOR CMOS LSI APPLICATIONS

This safety guideline was technically approved by the Silicon Wafer Committee and is the direct responsibility of the Japanese Silicon Wafer Committee. Current edition approved by the Japanese Regional Standards Committee on January 11, 2002. Initially available at www.semi.org January 2002; to be published March 2002. Previously published November 2001.

1 Purpose

1.1 This specification defines thin-layer silicon-on-insulator (SOI) wafer requirements for CMOS large scale integrated circuit (LSI) devices. In another aspect, this specification defines the generic characteristics of SIMOX and bonded silicon-on-insulator wafers having typically no more than 0.2 μm SOI layer thickness. By defining parameters, inspection procedures and acceptance criteria, both users and suppliers may uniformly define product characteristics and quality requirements.

2 Scope

2.1 This specification is specifically directed to SIMOX and bonded silicon-on-insulator wafers, which are exclusively used for LSI applications made up of CMOS devices.

2.2 A complete purchase specification requires the base silicon wafer, SOI surface and layer, and buried oxide layer properties detailed in this standard, suitable test methods for their characterization. SEMI M18 may be for purchase specification purpose.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

4 Terminology

4.1 Many terms relating to silicon technology are defined in ASTM Terminology F 1241. Other terms are defined as below.

4.2 *Abbreviations and Acronyms*

4.2.1 *BOX* — buried oxide layer

4.2.2 *SIMOX* — separation by implanted oxygen

4.3 *Definitions*

4.3.1 *bonded interface* — the plane where the bonding between handle and device wafers takes place.

4.3.2 *bonded wafer* — an SOI wafer made by bonding two silicon wafers with an insulating layer between them. The insulating layer is typically thermally grown oxide.

4.3.3 *BOX pin-hole* — electrically conductive path through the BOX.

4.3.4 *buried oxide layer* — the silicon dioxide layer between SOI layer and base silicon substrate.

4.3.5 *handle wafer or base silicon wafer or base silicon substrate* — the substrate which structurally supports the BOX and the SOI layer.

4.3.6 *HF defect* — defect in the SOI layer decorated by immersing the wafer in HF for a certain time.

4.3.7 *non-SOI edge area* — an annulus between the nominal radius of the surface silicon layer and the nominal radius of the base silicon wafer (for bonded SOI wafers). The annulus which implies an area is determined by its width as one dimension. It is the difference in the nominal radius of the surface silicon layer and the base silicon wafer.

4.3.8 *SIMOX wafer* — SOI wafer made by oxygen implantation technology

4.3.9 *SOI etch pit* — defect in an SOI layer decorated by immersing the wafer in Secco etch solution.

4.3.10 *SOI layer or surface silicon layer* — the silicon layer on the BOX of the SOI wafer.

4.3.11 *void* — local absence of SOI layer and/or BOX in bonded wafer.

5 Ordering Information

5.1 Purchase orders for SIMOX or bonded silicon-on-insulator wafers furnished to this specification shall include the following items:

- Characteristics for the SOI layer (thickness, crystal orientation, dopant, etc.)
- Characteristics for the base silicon substrate (thickness, crystal orientation, dopant, etc.)
- Characteristics of the buried oxide (thickness, dielectric breakdown voltage, etc.)
- Misalignment of wafer orientation between the SOI layer and the handle wafer
- Sampling plan and lot acceptance procedures (see Section 7)
- Methods of test and measurements (see Section 8)

6 Requirement

6.1 Requirements of SOI wafers consists of a base silicon wafer specification part and an SOI wafer specification part. A base silicon wafer is specified based on a SEMI M18 format. A similar format is applied for the specification of an SOI wafer.

2 Japanese Electronic and Information Technology Industries Association, Tokyo Chamber of Commerce and Industry Bldg. 2-2, Marunouchi 3-chome, Chiyoda-ku, Tokyo 100-0005, Japan. Website: www.jeita.or.jp

3 American National Standards Institute, New York Office: 11 West 42nd Street, New York, NY 10036, USA. Telephone: 212.642.4900; Fax: 212.398.0023 Website: www.ansi.org

6.2 As a minimum, the base silicon wafer shall conform to SEMI M1 and the appropriate individual polished monocrystalline silicon wafer standard; i.e. JEIDA 27.

6.3 SOI wafer specified items and test methods are listed in Table 1 and shall not exceed the limits as given in Table 1.

NOTE 1: to be specified or discussed between users and suppliers
NOTE 2: typically 0.1 μm and thicker SOI are specified. Thinner SOI is to be discussed between users and suppliers.
NOTE 3: It is specified by a distance from the FQA boundary to the periphery of a base wafer of nominal dimensions. It is not a distance from an edge of an SOI layer.
NOTE 4: JEITA Standards "One-Nanometer-Order Z-Axis Calibration Height of AFM" will be available in April 2002.
NA: not applicable
LD: Low dose SIMOX with BOX thickness ≤ 200 nm
HD: High dose SIMOX with BOX thickness > 200 nm

7 Sampling Plan

7.1 Unless otherwise specified, ASTM Practice E 122 shall be used. When so specified, appropriate sample sizes shall be selected from each lot in accordance with ANSI/ASQC Z1.4. Each quality characteristic shall be assigned with an acceptable quality level (AQL) of lot tolerance percent defective (LTPD) value in accordance with ANSI/ASQC Z1.4 definitions for critical, major, and minor classifications. If desired and so specified in the contract or order, each of these classifications may alternatively be assigned cumulative AQL or LTPD values. Inspection levels shall be agreed upon between users and suppliers.

8 Test Methods

8.1 *Thickness of Surface Silicon Layer and Buried Oxide Layer*

8.1.1 *Measurement Methods* — Two non-contact, non-destructive optical characterization techniques, spectroscopic ellipsometry (SE) and spectroscopic reflectometry, have proven useful both for surface silicon layer and buried oxide (BOX) layer thickness measurements. Both techniques use reflected light to allow deduction of the thickness and refractive index of thin layers. In both cases, layer thickness and index of refraction data must be "backed out" of the measured optical data by a process of successive approximation. Silicon islands in the BOX layer of SIMOX and interface non-uniformity make these techniques less reliable.

8.1.1.1 *Spectroscopic Ellipsometry (SE) Measurement* — In this measurement, white light from a xenon arc lamp passes through a polarizing rotating filter and illuminates the sample site under study; reflected light passes through an analyzer to a monochrometer and photomultiplier detector. For each wavelength, reflectivity oscillates with polarizer rotation; the magnitude and phase of reflectivity changes are measured to determine ellipsometric angles, δ and Ψ. The two measured spectra are fit by successive approximation to allow determination of the surface silicon layer and BOX layer thickness and oxide composition. For SE, the choice of instrument and associated model and fitting parameters affect the confidence-of-fit, so they should be taken into account in the user-supplier agreement.

8.1.1.2 *Spectroscopic Reflectometry Measurement* — In this measurement, light from a xenon arc lamp passes through a grating monochrometer or optical band-pass filters and illuminates the sample site under study; reflected light is gathered by a detector. Specular reflectivity is plotted as a function of wavelength from 0.4 µm to 1.1 µm. The analysis proceeds by making successively better approximations to index of refraction and absorption of each layer until an acceptable fit is achieved. Measurements are made with a reflectance mode optical interferometer.

8.1.1.3 *Optical Model Fitting and Correlation* — There are slight, systematic differences between layer thickness measured by SE and spectroscopic reflectometry. Because of this, users and suppliers should specify the actual measurement method to be used. The two methods offer results which are reproducible and well-correlated with each other over a wide range of conditions. If both measurement techniques are used, it is recommended that the reflectance system measurements should be calibrated to fit the results of the SE.

8.1.2 *Measurement Positions* — The measurement strategy is to make a detailed measurement with an accurate fit on at least nine wafer sites, for example, the wafer center, four points at half of the wafer radius and four points at 10 mm from the wafer edge. The number and position of wafer sites to be monitored should be agreed on between users and suppliers. Generally, the greater the variability relative to the mean, the larger the number of sites that should be monitored. In each case, the measurement system supplies a "goodness-of-fit" parameter that indicates a level of confidence in the fit to the measured data.

8.1.3 *Surface Silicon Layer and Buried Oxide (BOX) Layer Thickness* — Spectra for each site are fit independently with both the surface silicon and BOX layer thickness as adjustable parameters. Both the mean thickness and the uniformity should be specified.

8.1.4 *Surface Silicon Thickness Mean Value Variation*

8.1.4.1 After surface silicon layer thickness is measured for predetermined number of wafers and mean value of surface silicon thickness is derived for each wafer, the maximum and the minimum values are chosen, and then the variation (nm) is calculated as;

$$\pm \text{(Maximum mean value – Minimum mean value)} / 2$$

8.1.4.2 In case of quite large number of wafers (ex. a few hundreds), the variation (mm) can be calculated as;

$$\pm 3\sigma \text{ (3 times of the standard deviation)}$$

under agreement between users and suppliers.

8.1.5 *Surface Silicon Thickness Variation in Wafer*

8.1.5.1 After surface silicon layer thickness is measured at predetermined number of points within an SOI wafer, the maximum and the minimum values are chosen, and then the variation (nm) is calculated as ;

$$\pm \text{(Maximum value – Minimum value)} / 2$$

8.1.5.2 In case of multi-points measurements (ex. a few hundreds) within an SOI wafer, the variation (nm) can be calculated as;

$$\pm 3\sigma \text{ (3 times of the standard deviation)}$$

under agreement between users and suppliers.

8.1.6 *Buried Oxide (BOX) Thickness Variation*

8.1.6.1 After BOX thickness is measured for predetermined number of points on predetermined number of wafers, the maximum and the minimum values are chosen, and then the variation (%) is calculated as;

$$\pm \text{(Maximum value – Minimum value)} \times 100 / (2 \times \text{mean value})$$

8.1.6.2 In case of multi-points measurements (ex. a few hundreds) within an SOI wafer or quite large number of wafers (ex. a few hundreds), the variation (%) can be calculated as;

$$\pm 3\sigma \text{ (3 times of the standard deviation)} \times 100 / \text{(mean value)}$$

under agreement between users and suppliers.

8.2 *Dopant Concentration*

8.2.1 Secondary Ion Mass Spectroscopy (SIMS) is utilized to determine dopant concentration in surface silicon layer.

8.2.2 The acceptable dopant concentrations are to be determined by agreement between users and suppliers.

8.3 *Defects in Surface Silicon Layer*

8.3.1 *SOI Etch Pit*

8.3.1.1 Defects in surface silicon layer including stacking faults, threading dislocations and other crystal defects are evaluated by destructive chemical etching and microscopic etch pit density measurements. The appropriate evaluation procedure for SOI wafers, which depends on type of defects targeted and thickness of surface silicon layers, is determined by agreement between users and suppliers.

8.3.1.2 Following are examples of the evaluation on SIMOX wafers and bonded wafers.

8.3.1.3 *Example 1* — SOI etch pit evaluation in SIMOX wafers: Samples are first immersed in HF to remove oxide from the surface. Then the samples are etched by Secco etch. In the case of a relatively thick SOI layer such as 170–200 nm, freshly prepared standard Secco Etch can be used: one part (by volume) of a 0.15 molar solution of $K_2Cr_3O_7$ in distilled water and two parts HF (49%). In the case of a thin SOI layer below 100 nm, the samples are etched for 30 seconds in the solution[4]: 50 ml of HF (49%) plus 80 ml of HNO_3 (61%) plus 160 ml of H_2O [$K_2Cr_2O_7$ 1g + $Cu(NO_3)_2 \cdot 3H_2O$ 4g] (a sort of diluted Secco etch). For both cases, the etching should continue until 50 nm of the surface Si remains. After the etching and rinsing in water, samples are dipped in HF (49%) for 5 minutes. The HF etches the buried oxide and creates cavities under the etch pits. The number of etch pits is counted through optical microscope. The etch pits include various defects such as threading dislocations and stacking fault pyramid.

8.3.1.4 *Example 2* — SOI etch pit evaluation in bonded SOI wafers fabricated by delamination followed by CMP: SOI etch pit density increases when remaining SOI thickness after Secco etching is thinner and thinner. SOI layers thicker than 150 nm are usually etched down to 50 nm by Secco etching before SOI etch pits are counted. These pits are detected when selectively etched depth or the size of defects is larger than SOI layer thickness remaining after Secco etching. Thus, damages deeper than 50 nm or defects larger than 50 nm can be detected. These pits come from defects contained in original silicon material and/or damages or defects induced in SOI fabrication process. The former includes COP, bulk micro defects, oxygen precipitates, and so on. The latter includes CMP damages, defects induced by heat cycles and so on, as possibility. To define origins of SOI etch pits, their distribution in depth of SOI layers and/or that on a wafer should be evaluated. For example, CMP damages may be localized on surface of SOI layers. By etching SOI surfaces up to desired depth with using non-selective etching such as KOH followed by Secco etching, etch pits due to CMP damages disappear. The depth distribution of defects or damages can be evaluated in this manner.[5]

8.3.1.5 *Example 3* — SOI etch pit evaluation in bonded SOI wafers formed by epitaxial layer transfer technology: In this case, there is no COP, bulk micro defects, and oxygen precipitates in the SOI layer because it is made of epitaxially grown Si on porous Si. In addition, mechanical damage related defect is not introduced, since the SOI surface is smoothed out by hydrogen annealing instead of polishing. The major defect in this type of SOI wafers is same sided pyramidal stacking fault, that is induced at the initial stage of the epitaxy, and is grown through the epitaxy with upside-down pyramidal shape[6], and then is turned upside-down again by bonding. This defect is decorated as the etch pit by standard or diluted Secco's etching as described in Example 1 in conjunction with HF dipping. It is enough to etch until 50 nm of the SOI layer remaining to etch the defect portion through the SOI layer selectively by the defect etching such as Secco etching because the stacking fault penetrates through the SOI layer. The following HF dipping etches the BOX through the etch pit to form large cavity. It helps to count low density of defects in a wide observation area with low magnification microscope.

8.3.2 *Threading Dislocation*

8.3.2.1 The etching of the SIMOX sample shown above in Section 8.3.1.3 (Example 1) is terminated when the remaining surface silicon layer thickness is 1/3–1/2 of the initial thickness and then dipped in HF as the same manner as Example 1. In this case the etch pits include mainly threading dislocations only which can be counted through optical microscope.

8.3.3 *HF Defect*

8.3.3.1 Measurement of the microscopic etch pit density following an HF etch is commonly used to disclose defects in SOI material. Pitting of surface silicon may be present before the HF etch or be caused by HF etching. For this destructive measurement, a whole wafer or at least one quarter of a wafer should be used. The sample is placed in concentrated (49%) HF for 10 to 15 minutes or diluted (e.g. 25%) HF for longer time (e.g. 3 to 4 hours), then removed, rinsed and dried. If there are pits or voids and/or metal particles or silicides formed in the surface silicon layer, the HF etches the metals/silicides and then etch the buried oxide. This results in local etching of BOX with 25–50 μm diameter (depending on the HF concentration and the etch time) centered on the original defects. The defect density is then measured in an optical microscope using a 5× objective and 10× eyepiece or comparable setup. The samples should be scanned for whole surface within edge exclusion boundary.

8.3.4 *Void*

8.3.4.1 Voids are determined as an unbonded area on bonded SOI wafers. See SEMI M41. Because SOI layer in thin bonded SOI wafers are typically 0.2 μm thick or

4 L. F. Giles, A. Nejim, and P. L. F. Hemment, *Materials Chemistry and Physics*, vol.35, p. 129, 1993.

5 K. Mitani, H. Aga, and M. Nakano, *Jpn. J. Appl. Phys.* vol.36, p. 1646 1997.

6 N. Sato, K. Sakaguchi, K. Yamagata, Y. Fujiyama, J. Nakayama, and T. Yonehara, *Jpn. J. Appl. Phys.* vol.35, p. 973 (1996).

thinner, void areas are broken and SOI layers as well as BOX are usually absent. By this reason, voids are specified as local absence of SOI layers and/or BOX in bonded wafers in this specification.

8.3.4.2 *Visual inspection* — Under visible light, the edge of voids is detected because the edge area is step-shaped due to absence of SOI layers and/or BOX layers. See Section 8.8 for inspection conditions.

8.3.4.3 *Detection as large LLS* — The edge of local absence of SOI layer and/or BOX scatters light. Therefore, voids are detected as large LLS. See Section 8.7.2 for the principle. A size of LLS corresponding to various sizes of voids should be calibrated or correlated by comparison of defects one by one using a microscope.

8.4 *Surface Roughness*

8.4.1 *AFM (Atomic Force Microscope)* — By contacting the probe equipped with the cantilever onto the wafer surface of the sample, and by scanning the cantilever and detecting the variation by optical method, the roughness information is obtained. A tapping mode is commonly used.

8.5 *Metal Contamination*

8.5.1 The surface metal contamination can be measured by TXRF, AAS and ICP-MS methods.

8.5.2 *TXRF (Total X-Ray Fluorescence)* — Total X-ray Fluorescence uses a low angle incident, and a tightly collimated X-ray beam excites the characteristic X-rays from impurity atoms near the sample surface. Usually, the angle of X-ray incidence is less than 0.1 degree. The element identification and the amount of the element can be obtained by measuring energy and intensities of fluorescence X-ray. The instrument provides a map of impurity element distribution. Surface roughness may change metal detection sensitivity. Thus, calibration is suggested before samples with deferent level of roughness, e.g. back surface, are measured. A reference for details is ASTM F1526.

8.5.3 *AAS (Atomic Absorption Spectroscopy)*

8.5.3.1 The elemental characteristic absorption of the atom is measured by introducing sample solution as aerosol into the flame and then spectral absorption through the flame from the light source is detected by the spectrometer. The flameless method, superior to the flame method in the sensitivity, is now broadly used.

8.5.3.2 *Sample Preparation* — Careful sample preparation is necessary for the precise measurement. SOI wafer surface is exposed to HF vapor, and metals on the surface are collected as droplet. To improve sensitivity, the volume of collective solution should be as small as possible and HF drops are rolled all over the surface in collective operation. In case of precious metals, it is better to use other kinds of collective solutions instead, since they are not dissolved or collected by HF solution itself.

Examples:

1. For Cu ; HF-H_2O_2 (HF (50 wt.%) : H_2O_2 (31 wt.%): H_2O = 1 : 17 : 82 volume ratio)
2. For Au and Pt ; aqua regia (HNO_3 (68 wt.%) : HCl (36 wt.%) = 1 : 3 volume ratio)

8.5.4 *ICP-MS (Inductively Coupled Plasma Mass Spectroscopy)*

8.5.4.1 ICP-MS is composed of ICP (Inductively Coupled Plasma) part as an ion source and MS (Mass Spectrometer) part, which measures the ions generated at ICP part. Usually, sample solution is vaporized in the nebulizer and then finally introduced into Argon plasma in the silica tube called torch through the spray chamber. The sample is decomposed, evaporated, atomized and then ionized in the Argon plasma. Except for few atoms that have relatively high ionization potential, most of the elements (> 90%) can be ionized. Ions are identified and measured in amount by the mass spectrometer.

8.5.4.2 *Sample Preparation* — The same method as AAS method is applicable. In case of quantitative measurement of Fe, since its mass weight is close to that of ArO^+, it is necessary to pay attention to degradation of detection sensitivity.

8.6 *BOX Defect*

8.6.1 *BOX Pinhole Measurement-1 (by $CuSO_4$ plating or copper decoration)*

8.6.1.1 BOX pinhole evaluations shall be made by $CuSO_4$ plating or copper decoration methods. They can be also evaluated by BOX capacitor dielectric breakdown, the details of which are explained later in *BOX Pinhole Measurement-2*.

8.6.1.2 In evaluation by $CuSO_4$ plating method, the sample wafer is placed (front face down) on a paper towel soaked in 20% $CuSO_4$ solution on top of a copper plate. An aluminum plate is placed on the back of the wafer. The copper plate is grounded, and −25 V_{DC} is applied to the aluminum plate. Small leakage currents (sub-µA) through pinholes in the BOX cause copper to plate out onto the towel with the density same as BOX pinhole density.

8.6.1.3 In evaluation by copper decoration method, an SOI layer is first etched off by KOH solution to expose a BOX layer. Then the wafer is immersed in methanol and brought downward into direct contact with the gold-coated cathode. A copper mesh as an anode is immersed in the liquid 5 mm above the wafer. Required voltage is applied, such as the electric field in the buried oxide layer is 1 MV/cm. The voltage is measured at the oxide surface with a surface voltage probe. Localized copper decorations at pinhole sites in the oxide are observed with a low power optical microscope.

8.6.2 *BOX Capacitor Dielectric Breakdown* — This parameter can be measured with BOX capacitor. The BOX thickness affects both the test procedure (such as capacitor area and voltage criterion) and the allowable values of measured parameters. These should be determined by agreement between users and suppliers.

8.6.2.1 *Test Structure* — BOX capacitor utilizing mesa-etched SOI layers and Si substrates for both electrodes to apply electric field to the embedded buried oxide is used. The area of capacitor, which affects the breakdown voltage, should be determined by agreement between users and suppliers. Typical capacitor area is 0.01–0.1 cm^2. The electrode material and thickness affect the breakdown phenomena due to thermal effects, and so should be included in the agreement.

8.6.2.2 *Test Method: Staircase I-V Measurement* — Voltage is stepped in one-volt increments from zero to until destructive breakdown is sensed. The test detects the onset of high field conduction, as well as the point of destructive or massive charge injection and trapping.

8.6.3 *BOX Pinhole Measurement-2 (by Dielectric Breakdown)*

8.6.3.1 Buried oxide pinhole can be detected also by BOX capacitor.

8.6.3.2 *Test Structure* — BOX capacitor having an area equal to or greater than 0.05 cm^2.

8.6.3.3 *Test Method: Staircase I-V* — Measurement testing can be done for both Type I and Type II defects where Type I defects are silicon pipes traversing the buried oxide, and Type II defects are local regions of thin buried oxide. If Type II defect density is sought, capacitors are subjected to a series of 30 voltage steps of 3.3 volts, with current monitored after each step, using a failure criterion of 1 nA.

8.6.3.4 Any capacitor displaying the failure current or more for applied field less than 2 MV/cm is considered defective. Defect density of either type is calculated from the yield of good capacitors, (Y = 1 − # failed/# tested), using Poisson statistics;

$$D = -\ln(Y)/A,$$

where A is the total area of the capacitors tested.

8.7 *Particle (LLS : Localized Light Scatterer)*

8.7.1 *Light Scattering Tomography* — The particle larger than predetermined threshold size is counted by an automated particle counter.

8.7.2 *Principle of Measurement* — By scanning the laser beam on the wafer surface, the light scattered by particles on a wafer is detected. The scattered light and the noise from the wafer surface is detected as a direct current, on the other hand, the scattered light by the particles can be detected as pulse components. The particle size can be calibrated with standard polystyrene latex spheres. SOI wafers usually have scattering noise from the layer interface. It is necessary to reduce incident angle of the laser beam to increase the reflective component from the surface. For example, S/N ratio is improved when using S-polarized light of 10 degree incident, 85% of its component is reflected from silicon surface.

NOTE 1: Detailed procedure of size calibration with standard polystyrene latex spheres: Refer to ASTM F1620.

NOTE 2: Measurement procedure should be determined by agreement between users and suppliers.

8.8 *Visual Inspection* — SOI wafer can be visually inspected in accordance with ASTM F523. The automatic inspection equipment is also used when available. For visual inspection, the collimated high intensity bright light (e.g. 500,000 lux) is used. Under using this light, SOI wafer is inspected for haze, slip, scratches, chips, cracks, pits, dimples, mound, orange peel, voids, LLS and contamination.

SEMI M48-1101
GUIDE FOR EVALUATING CHEMICAL-MECHANICAL POLISHING PROCESSES OF FILMS ON UNPATTERNED SILICON SUBSTRATES

This guide was technically approved by the Global Silicon Wafer Committee and is the direct responsibility of the North American Silicon Wafer Committee. Current edition approved by the North American Regional Standards Committee on August 27, 2001. Initially available at www.semi.org September 2001; to be published November 2001.

1 Purpose

1.1 The purpose of this document is to provide a guide for evaluation of chemical-mechanical polishing (CMP) processes of thin films on unpatterned silicon substrates. This includes recommended procedures for process testing and reporting formats.

1.2 This guide is intended for use by both suppliers and end users.

2 Scope

2.1 This document provides a guide for evaluating a CMP process for films deposited or grown on an unpatterned silicon substrate. These evaluations could include tests with fixed polishing time, fixed removal rate, fixed ending thickness, time-dependent material removal, and others.

2.2 Recommended procedures for characterizing a CMP process are discussed in this guide.

2.3 This guide suggests selected parameters and values of the properties of the starting monitor wafer.

2.4 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety health practices and determine the applicability or regulatory limitations prior to use.

3 Limitations

3.1 The guide does not address evaluation of CMP processes for films on patterned substrates.

3.2 Evaluation of surface quality or surface contamination is not addressed in this document. Surface quality and surface contamination are important aspects of the CMP process evaluation but they are beyond the scope of this guide.

3.3 This guide employs sample standard deviation to estimate variation.

3.4 Wafer positioning precision on a metrology tool can affect the precision of the polishing evaluation. This issue is not addressed in this standard.

3.5 The values derived from the calculations in this guide are sample-dependent. They are affected by measurement location and number of observations.

5 Terminology

5.1 *blanket polish* — polishing of material deposited on an unpatterned silicon substrate.

5.2 *diameter scan* — measurements of material on a wafer taken along a specified diameter. The diameter scan is useful in determining the thickness profile of the material on the wafer surface.

5.3 *edge scan* — measurements of material taken along a specified radial segment in the edge region of the wafer. A series of edge scans can be employed to determine circumferential thickness profile.

5.3.1 *Discussion* — the data density for edge scan measurements is generally higher than for other measurements. Combining a low-density diameter scan in the central region of the wafer with a higher-density edge scan, taken along the same scan line, can improve throughput with appropriate local measurement data density.

5.4 *film total thickness variation (film TTV)* — the total thickness variation ($Thk_{max} - Thk_{min}$) of film material among a set of measurement points.

5.4.1 *Discussion* — The variation may pertain to a region within a wafer, a complete wafer or multiple wafers with a single polish head, or multiple wafers with multiple polish heads. These wafer and head combinations must be considered in planning and comparing measurements. If one assumes that a given wafer is polished by a subset of the tool heads (typically one), a hierarchical relationship exists such that wafers must be associated with the (tool head) subsets used to polish them. Another way to look at this is, if *head* is considered an experimental treatment, then a wafer polished by one head will be assumed to be treated differently than a wafer polished by a different head. This relationship leads to what is known as a hierarchic or nested model. (In this case, one says that wafer is nested within *head*). A more complete model would also treat *head* as a fixed effect, *wafer* random and nested within *head*, and error as nested with *head* and *wafer*. A random effect indicates that the observation comes from a random sample of a larger population. *Head* is a fixed effect because the entire population of heads (i.e., all the heads on the tools) constitutes the entire population of interest. Given this model, variance components would be used to estimate the different sources of variation. In this case, the sample standard deviation underestimates the population standard deviation. Historically, the expected value of the variance components is equal to the population standard deviation. This is not the case for the sample standard deviation.

5.5 *head to head removal rate non-uniformity (HTHNU)* — this metric is useful when evaluating polishing processes on a multi-head tool configuration. It is the standard deviation (1σ) of the removal rate variation from polish head (HTH) to polish head for a fixed number of wafers where the number of wafers run for each head must be equal. It is expressed as follows:

$$HTHNU = \sqrt{\frac{\sum_{k=1}^{p}\left(\overline{RR_k} - \overline{\overline{RR_{HTH}}}\right)^2}{p-1}} \quad 1)$$

Where k is the head indexer and p is the total number of heads. $\overline{RR_k}$ is the average within wafer removal rate of head k. $\overline{\overline{RR_{HTH}}}$ is the head to head wafer removal rate averaged across all wafers and all heads. The measurement site locations on each wafer must be identical for all wafers sampled.

It may also be expressed as a percentage of the average head to head removal rate:

$$\%\ HTHNU = \frac{\sqrt{\frac{\sum_{k=1}^{p}\left(\overline{RR_k} - \overline{\overline{RR_{HTH}}}\right)^2}{p-1}}}{\overline{\overline{RR_{HTH}}}} \times 100 \quad 2)$$

5.6 *removal rate (RR)* — the amount of material removed per unit time during the polish process. At any given point i on the wafer, the removal rate is expressed by

$$RR_i = \frac{Thk_{pre_i} - Thk_{post_i}}{\text{Polish time}} \quad 3)$$

5.7 *thickness, prepolish (Thk_{pre})* — the thickness of material on an incoming blanket film wafer prior to polish.

5.8 *thickness, post-polish (Thk_{post})* — the thickness of material remaining at a measurement site on a silicon substrate after completion of the polish process.

5.9 *wafer to wafer (WTW) variation* — the variation across multiple wafers at site locations where the locations on each wafer are identical for all wafers sampled.

5.10 *wafer to wafer removal rate nonuniformity (WTWNU)* — a measure of the wafer to wafer removal rate variation. It is the standard deviation (1σ) of the removal rate variation wafer to wafer over a polish run that employs a single polishing head. The average removal rate for such a group of wafers is expressed as:

$$\text{Average WTW RR} \Rightarrow \overline{\overline{RR}}_{WTW} = \sum_{j=1}^{m} \frac{\overline{RR_j}}{m} \qquad 4)$$

where *j* is the wafer indexer and *m* is the total number of wafers within the group. A typical number for m is ≥ 25.

The measurement site locations on each wafer must be identical for all wafers sampled. The wafer-to-wafer removal non-uniformity is expressed as follows:

$$WTWNU = \sqrt{\frac{\sum_{j=1}^{m} \left(\overline{RR}_{WIW} - \overline{\overline{RR}}_{WTW}\right)^2}{m-1}} \qquad 5)$$

It may also be expressed as a percentage of the average wafer to wafer removal rate:

$$\% \, WTWNU = \frac{\sqrt{\frac{\sum_{j=1}^{m} \left(\overline{RR}_{j_{WIW}} - \overline{\overline{RR}}_{WTW}\right)^2}{m-1}}}{\overline{\overline{RR}}_{WTW}} \times 100 \qquad 6)$$

5.11 *within wafer average removal rate* — the average removal rate within a wafer. It is given as

$$\text{Average WIW RR} \Rightarrow \overline{RR}_{WIW} = \sum_{i=1}^{n} \frac{RR_i}{n} \qquad 7)$$

where *i* is the site indexer and *n* is the total number of measurement sites within the wafer, and RR_i is within wafer removal rate.

5.12 *within wafer removal rate nonuniformity (WIWNU)* — a measure of removal rate variation. It is the standard deviation (1σ) of the removal rate within the wafer and is expressed as follows:

$$WIWNU = \sqrt{\frac{\sum_{i=1}^{n} \left(RR_i - \overline{RR}_{WIW}\right)^2}{n-1}} \qquad 8)$$

where *i* is the site indexer, *n* is the total number of measurement sites on the wafer and $\overline{RR_{WIW}}$ is the average within wafer removal rate. It may also be expressed as a percentage of the average removal rate:

$$\% \, WIWNU = \frac{\sqrt{\frac{\sum_{i=1}^{n} \left(RR_i - \overline{RR}_{WIW}\right)^2}{n-1}}}{\overline{RR}_{WIW}} \times 100 \qquad 9)$$

5.13 *within wafer (WIW) variation* — the variation in measurement values obtained at defined locations within a single wafer.

6 CMP Process Test

6.1 *Introduction*

6.1.1 The CMP process test should be performed with attention to the quality of both the substrate and the incoming film material, and the relative condition of the consumables and polishing system being utilized.

6.1.2 The number of wafers within the group should be specified.

6.2 *Monitor Wafer*

6.2.1 Monitor wafer specifications should be per SEMI M1 for incoming bow, warp, total thickness variation (TTV), and edge profile.

6.2.2 The geometry of the wafer may influence the CMP process results. Tables R-1 and R-2 in Related Information 1 recommend specifications for wafer geometry that can minimize the effects of such geometry on the CMP process test.

6.2.3 Record bow, warp and other wafer geometry characteristics.

6.2.4 Wafers can be laser-marked for ease of tracking. Data taken in this mark area should be excluded from the process analysis. It is desirable that all wafers in an evaluation lot contain marks at the same nominal locations.

6.3 *Incoming Film Properties*

6.3.1 Record the incoming film type and deposition tool and, where applicable, the deposition process conditions.

6.3.2 Ascertain that the incoming film thickness is sufficient to prevent polishing through to the substrate. See Tables R-1 and R-2 in Related Information 1 for recommended values for incoming film thickness.

6.4 *Post-process Measurements*

6.4.1 Record bow, warp and the same other wafer geometry characteristics determined in Section 6.2.3.

NOTE 2: These post-process measurement values may vary arbitrarily relative to the pre-process values.

6.4.2 Record final film thickness in the same locations employed for the starting film.

6.4.3 Calculate global and local film thickness changes appropriate for the application of interest.

6.5 *Metrology tools*

6.5.1 Select a film thickness measurement system suitable for the film and sampling pattern to be characterized.

6.5.1.1 Perform a gauge study on each metrology tool accordance with SEMI E89 to determine its effectiveness for the films to be measured.

6.5.2 Ascertain that the metrology tool is operating properly under Statistical Process Control prior to use in the CMP process test.

6.5.3 Perform tool calibration in accordance with the tool supplier's instructions.

6.6 *CMP Consumables*

6.6.1 Identify all consumables including pad, insert film, slurry type, and conditioning end effector.

6.6.2 Record the manufacturer's part number and lot number (if available) of each consumable item.

6.6.3 Record the status and history of each consumable prior to starting the process test.

NOTE 3: The history of consumables can affect the CMP process test.

6.6.4 Perform break-in procedures for pad and carrier film as required to ensure stable operation. Base these break-in procedures on recommendations from the consumable supplier.

6.7 *Polishing Tool*

6.7.1 Calibrate and record polish downforce, alignment tolerances, velocity, fluid dispense rates and other operational parameters based on recommended procedures from the equipment manufacturer.

6.7.2 Polish the samples.

7 Measurement Locations on the Wafer

7.1 The number and location of measurement sites are specific to the process test. In general, locations should be evenly spaced. Data extrapolation beyond the boundary of the measurement site population should not be performed.

7.2 ASTM F 1618 covers a set of site distribution patterns for measuring the uniformity of a thin film on a silicon wafer, similar to Figures 2 – 5, as well as simple procedures for analyzing and reporting the results of those measurements. For edge-scan measurements, see Section 7.3.6 below. For spiral-scan measurements, see Section 7.3.7 below. For full-wafer, high-density measurements, see Section 7.3.10 below.

7.3 Select one of these patterns for CMP process analysis on unpatterned wafers, unless otherwise agreed to.

7.3.1 Sampling plans are based on concentric circles, spirals, Cartesian sites, partial-radius, and partial and single-diameter sites.

7.3.2 Measurements are made at the sites specified in the chosen sampling plan, using the appropriate instrumentation and measurement procedure for the film parameter of interest.

7.3.3 Measures of the dispersion of the values are obtained by simple statistics specified for the sampling plans.

7.3.4 For diagonal scan measurements, refer to Figure 1. Select values for each of the following scan parameters:

- Scan Angle, θ
- Scan Radius Start/Stop, r_1 / r_2
- Number of Measurement Points, n, across the diameter.

7.3.5 For edge scan measurements, refer to Figure 6. Select values for each of the following scan parameters:

- Scan Angle, θ
- Inner Scan Radius, r_1
- Outer Scan Radius, r_2
- Number of Measurement Points, n, between r_1 and r_2.

NOTE 4: These n measurement sites are uniformly distributed.

7.3.5.1 *Discussion* — the data density for edge scan measurements is generally higher than for other measurements. Combining a low-density diameter scan in the central region of the wafer with a higher-density edge scan, taken along the same scan line, can improve throughput with appropriate local measurement data density.

7.3.6 For spiral scan measurements, refer to Figure 7. In such scans, the measurements are evenly distributed from near the center (r = 0) to near the edge exclusion boundary (r = 1 – EE). For each successive point, both the radius and the angle θ are systematically changed. For the 200 mm example with 3 mm edge exclusion shown in Figure 7, the 81 measurement points start at

R_1 = 0.10 mm and θ_1 = 0.52°. Successive points are incremented with ΔR = 1.21 mm and $\Delta\theta$ = 1.16°.

NOTE 5: Spiral scans uniformly sample properties that are radially symmetrical. These scans apply equal weight to all measurement sites. They also provide radial information, similar to diameter scans, as well as additional theta-related information that may not be provided by diameter scans.

7.3.7 For concentric circle scans, refer to Figures 2 and 3. In these scans, the inner circles lie on a fraction of the nominal radius. For notched wafers, the outer circle lies on a radius equal to the nominal radius less the edge exclusion, which is conformal with the notch on notched wafers. For flatted wafers the outer circle lies on a radius equal to the nominal radius less the sum of the flat depth plus the edge exclusion.

7.3.8 For Cartesian measurement scans, refer to Figure 4.

7.3.9 For full-wafer measurements, the measurements sites are evenly spaced over the entire area being examined. Typically, the first point is the wafer center, and the remaining measurement sites are equally spaced about the wafer center in X and Y. This X-Y grid is similar to Figure 4, but with significantly higher spatial density.

7.4 Record and identify the measurement site locations in accordance with SEMI M20.

7.4.1 Include an illustration of these locations with the test setup and with the recorded data set.

SEMI M49-1101
GUIDE FOR SPECIFYING GEOMETRY MEASUREMENT EQUIPMENT FOR SILICON WAFERS FOR 130 nm TECHNOLOGY GENERATION

This guide was technically approved by the Global Silicon Wafer Committee and is the direct responsibility of the North American Silicon Wafer Committee. Current edition approved by the North American Regional Standards Committee on August 27, 2001. Initially available at www.semi.org September 2001; to be published November 2001.

1 Purpose

1.1 This document provides a guide for specifying measurement equipment for geometry and flatness of silicon wafers of the 130 nm technology generation as anticipated by the International Technology Roadmap for Semiconductors (ITRS), 1999 edition and in the forecasts of the major manufacturers of semiconductor devices. Wafer parameters as defined by SEMI M1, M24 or M38 are specified by customers of Si wafer suppliers and are usually part of Certificates of Compliance. Suppliers of Si wafers and their customers might measure these parameters using equipment provided by different manufacturers of such equipment or using different generations of equipment of one supplier. Agreement on basic features and capability of such measurement equipment improves data exchange and interpretation of data as well as procurement of appropriate tools.

2 Scope

2.1 This guide outlines and recommends basic specifications for equipment for measuring geometry and flatness of Si wafers of 130 nm technology generation.

NOTE 1: Future revisions of this guide are expected to reflect changed requirements for the 130 nm node as well as requirements of other nodes.

2.2 The guide applies to measurement equipment used for verifying the quality parameters geometry and flatness in large scale production of bare polished or epitaxial Si wafers the backside of which may be acid etched and/or covered by unpatterned, homogeneous layers of e.g. poly-Si or LTO (low temperature oxide). Artifacts (e.g., reference materials) for calibrating measurement equipment might have different properties.

2.3 The guide also applies to measurement equipment that provides only a subset of the measurement features outlined in Table 3.

2.4 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety health practices and determine the applicability or regulatory limitations prior to use.

3 Limitations

3.1 The document does not apply to measurement equipment used to control intermediate process steps during Si wafer manufacturing. However, it may be completely or partly used for measurement equipment for those applications provided corresponding constraints are appropriately identified.

3.2 The document also does not apply to measurement equipment for SOI wafers or patterned wafers.

5.1.8 *SECS* — SEMI Equipment Communications Standard

5.1.9 *XML* — Extensible Markup Language

5.2 *Definitions*

5.2.1 *bias* — the difference between the average of measurements made on the same object and its true value. Sufficient measurements are needed to mitigate the effects of variability. (SEMI E89)

5.2.2 *calibration* — calibration is a measurement process that assigns value to the property of an artifact or to the response of an instrument relative to reference standards or to a designated measurement process.

NOTE 3: The purpose of calibration is to eliminate or reduce bias in the user's measurement system relative to the reference base. The calibration process compares an unknown or test item or instrument with reference standards according to a specific algorithm, often in the form of a specific calibration curve. (SEMI E89)

5.2.3 *compatibility* — the capability of measurement equipment to emulate the measurement process of other tools. Downward compatibility refers to former generation(s) of the same or similar type of equipment of an equipment supplier.

NOTE 4: Compatibility can be provided by a measurement mode in which filtering, spatial resolution, etc. of another, older, tool is imitated.

5.2.4 c*orrelation* — the relation of measurement results obtained by repeated measurements with the same set of test specimen(s) and any two measurement tools expressed in terms of a regression curve.

5.2.5 *matching tolerance* (Δ_m) — the difference in bias for any two measurement tools of the same kind. Otherwise matching tolerance tests are performed under the conditions of σ_3 tests.

NOTE 5: In the absence of certified or standard reference materials matching may be tested by using appropriate wafers complying with 130 nm technology node specifications. It is recommended to test for matching with a set of samples covering the parameter range of interest.

5.2.6 *precision over tolerance (P/T) ratio* — the ratio of the precision of measurement equipment and a product's tolerance. (SEMI M27)

5.2.7 *level 1 variability* (σ_1) — the variation (standard deviation) of measurement results obtained by repeated measurements with the same test specimen(s) and the same measurement tool under nominally identical conditions without replacing the test specimen between subsequent measurement runs. σ_1 tests are performed with a single calibration in the shortest possible time interval.

5.2.8 *level 2 variability* (σ_2) — the variation (standard deviation) of measurement results obtained by repeated measurements with the same test specimen(s) and the same measurement tool with replacing the test specimen between subsequent measurement runs but otherwise under nominally identical conditions. σ_2 tests are performed with a single calibration in the shortest possible time interval.

5.2.9 *level 3 variability* (σ_3) — the variation (standard deviation) of measurement results obtained by repeated measurements with the same test specimen(s) and the same measurement tool with replacing the test specimen between subsequent measurement runs but otherwise under nominally identical conditions. σ_3 tests are performed over a time period greater than σ_2 tests without operator induced adjustment.

5.2.10 *sorting* — real and virtual separation of test specimens in different categories specified by one or multiple parameters.

5.2.11 *tolerance* — the absolute magnitude of the range of the product specification. (SEMI M27)

6 Specification for Measurement Equipment for Silicon Wafers of 130 nm Technology Generation

6.1 The specification is structured in three sections (Tables 1–3):

- Generic Equipment Characteristics (Table 1)
- Materials to be measured (Table 2)
- Metrology Specific Equipment Characteristics (Table 3)

6.2 Tables 1–3 contain the specifications, referenced documents, test methods, and comments. Additional explanations and discussions are provided in this section.

6.3 Generic Equipment Characteristics (Table 1)

6.3.1 The section "Generic Equipment Characteristics" consists of five subsections:

- Wafer handling
- Reliability
- Procedural
- Documentation
- Computer/User Interface/Connectivity

6.3.2 Subsections covering “Facilities Requirements” and “Safety/Legal/Regulatory” are not included in the present document as these issues are highly user specific and dependent on national regulations.

6.4 *Materials to be measured (Table 2)*

6.4.1 Table 2 specifies the parameters of Si wafers that the measurement equipment must be capable to handle and to measure.

6.5 *Metrology Specific Equipment Characteristics (Table 3)*

6.5.1 This section specifies the dimensional parameters of Si wafers to be measured and to be reported by equipment for measuring the geometry and flatness of wafers as well as the required spatial resolution, precision and accuracy of the measurement equipment.

6.5.2 The ability of a metrology tool to properly measure surface features of different spatial wavelengths is affected by the spatial bandwidth of the tool's response function. Spatial bandwidth can be defined in many ways and is influenced by many factors beyond the scope of this document. Some of these need to be standardized.

6.5.3 Spatial resolution is defined by the high spatial frequency limit of the bandwidth of the tool's response function.

6.5.4 Low and high cut-off frequency f_{min} and f_{max} define the bandwidth of the response function of measurement equipment. The cut-off frequencies correspond to an attenuation of 0.5 for the amplitude of a sinusoidal surface feature with the exception of a low pass filter ($f_{min} = 0$) for which the attenuation remains 1 at f_{min}.

6.5.5 The rate of change of the attenuation approaching the cut-off frequencies has to be larger than the rate of a Gaussian filter with the corresponding cut-off frequency.

6.5.6 The present document recommends f_{max} and f_{min} that must be measured by the instrument.

6.5.7 Any variations in filtering procedures applied near the FQA boundary must be described by the supplier of the equipment.

6.5.8 The bandwidth as specified in Table 3 is a nominal value.

6.5.9 In the present document a hierarchy of variability levels is used to describe the performance of measurement equipment which is calibrated and adjusted/aligned according to the supplier's procedures. The various terms are defined in section 5. These variability levels are consistent with terms defined in SEMI E89 but not fully interchangeable. Their relation is indicated in parentheses.

6.5.9.1 Level 1 variability: standard deviation σ_1 (SEMI E89 static repeatability)

6.5.9.2 Level 2 variability: standard deviation σ_2 (SEMI E89 dynamic repeatability)

6.5.9.3 Level 3 variability: standard deviation σ_3 (SEMI E89 reproducibility)

6.5.10 In addition two levels of systematic off-set between different tools are defined:

6.5.10.1 matching tolerance (difference of means Δ_m)

6.5.10.2 correlation (regression curve)

6.5.11 Explicitly specified in the present document are only level 3 variability σ_3 and matching tolerance Δ_m as they correspond to the utilization of measurement equipment for wafer manufacturing most closely. The supplier of a specific tool may optionally provide specifications for level 1 and/or level 2 variability, respectively.

6.5.12 Level 3 variability σ_3 and matching tolerance Δ_m are specified with respect to anticipated specifications for wafer geometry and flatness as given in Table 3 for a reference wafer.

6.5.13 In the present document P/T-ratios are used for specifying level 3 variability σ_3.

6.5.13.1 A precision-to-tolerance ration P/T less than 10% at 6σ is recommended in SEMI M27 for metrology equipment. This would be an extremely demanding specification for flatness and geometry measurement tools. In addition, flatness characterisitics of Si wafers are typically described by a single sided distribution with the median approaching zero, the lower specification boundary. Therefore two grades that are based on 3σ criteria, instead on 6σ, are recommended for such tools in the present document:

- grade A: P/T < 10%, $3\sigma_3$
- grade B: P/T < 20%, $3\sigma_3$

6.5.13.2 The individual measurement features a tool provides may be graded differently, e.g. SFQR might meet grade A, but SBIR only grade B. This has to be indicated appropriately in the tools' technical specifications.

6.5.14 Matching tolerance is specified to be less or equal to $1.5\sigma_3$ of level 3 variability. This corresponds to a greater than 99% probability that the difference of any individual measurement results obtained with two different tools is smaller or equal to $5\sigma_3$.

6.5.15 The target for bias is a range of $\pm 1.5\sigma_3$ with respect to a certified value provided appropriate reference materials are available. This corresponds to a greater than 99% probability that any individual measurement is in the range of $\pm 4\sigma_3$ around the certified value when a reference material is tested.

6.5.16 Reference material with a series of surface features with appropriate height and half width is required to verify bandwidth of a measurement tool. The height of the features corresponds to the wafer specification as outlined in Table 3.

6.5.17 The specifications of the measurement equipment are verified by using wafers the parameters of which are in a range, the upper limit of which corresponds to 1.5 times anticipated wafer specification, the lower limit to 0.5 of anticipated wafer specification. These are listed in Table 3 as Reference Wafer Specifications.

NOTE 6: The edge region of wafers represents the most challenging area for meeting the desired performance characteristics. This is because of the larger surface geometry variations in the region near the edge, e.g. from polishing roll-off.

6.5.18 Reference Wafers that meet all requirements of Table 3 are not readily available (in 2000). Therefore it might be difficult to properly characterize and separate all contributions to measurement error.

6.5.19 Verification of bias, matching tolerance and the various levels of variability are performed with equipment which is calibrated according to the supplier's procedures and which is under statistical process control.

6.5.20 Compatibility of two tools is considered to be satisfactory when the specifications of the older tool are met with the newer tool operating in the emulation mode.

6.5.21 The quality of a correlation between different measurement equipment is not specified in the present document.

3.3 Calibration	automated method, Certified Reference Material (CRM) to be provided by equipment supplier			
3.3.1 Level 3 Variability Test Interval	user specific		to be recommended by supplier of measurement equipment	
3.4 Dependence of Results on Wafer Orientation	$< 1\sigma_3$			

SEMI M50-1101
TEST METHOD FOR DETERMINING CAPTURE RATE AND FALSE COUNT RATE FOR SURFACE SCANNING INSPECTION SYSTEMS BY THE OVERLAY METHOD

This test method was technically approved by the Global Silicon Wafer Committee and is the direct responsibility of the North American Silicon Wafer Committee. Current edition approved by the North American Regional Standards Committee on August 27, 2001. Initially available at www.semi.org September 2001; to be published November 2001.

1 Purpose

1.1 This test method provides a framework for the calculation of the capture rate (CR), false count rate (FCR) and cumulative false count rate (CFCR) of a scanning surface inspection system (SSIS) as a function of latex sphere equivalent (LSE) size of localized light scatterers (LLS).

NOTE 1: In the context of this document the term "size" refers to the LSE diameter.

2 Scope

2.1 This test method defines the SSIS capture rate and discusses its usage in industry specifications.

2.2 This test method addresses calculating and reporting SSIS capture rate from measurements of either PSL depositions or other LLS on wafers in LSE units.

2.3 Specific wafer surfaces (by wafer product, type of film or type of polish) that may affect the measured capture rate and false count rate of an SSIS are to be agreed upon between suppliers and users.

2.4 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety health practices and determine the applicability or regulatory limitations prior to use.

3 Limitations

3.1 This test method is limited to use on unpatterned wafers.

3.2 This test method is limited to use on calibrated scanners operated in a production mode.

ISO Guide 30:1992 — Terms and Definitions Used in Connection with Reference Materials

NOTE 2: Unless otherwise indicated, all documents cited shall be the latest published versions.

5 Terminology

5.1 *capture rate (CR)* — the probability that an SSIS detects an LLS of latex sphere equivalent (LSE) signal value at some specified SSIS operational setting.

5.2 *certified reference material (CRM)* — A reference material, accompanied by a certificate, one or more of whose property values are certified by a procedure which establishes its traceability to an accurate realization of the unit in which the property values are expressed, and for which each certified value is

1 American Society of Mechanical Engineers, United Engineering Center, 345 East 47th Street, New York, NY 10017

2 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, Pennsylvania 19428-2959, USA. Telephone: 610.832.9585, Fax: 610.832.9555 Website: www.astm.org

3 International Organization for Standardization, ISO Central Secretariat, 1, rue de Varembé, Case postale 56, CH-1211 Geneva 20, Switzerland. Telephone: 41.22.749.01.11; Fax: 41.22.733.34.30 Website: www.iso.ch

accompanied by an uncertainty at a stated level of confidence. [ISO Guide 30:1992]

5.3 *cumulative false count rate* (CFCR) — the number of false counts of size S_f, or larger, that are expected to be recorded by an SSIS at some specified operational setting as a function of S_f. CFCR may be found by averaging false counts over multiple scans.

5.4 *false count (FC)* — a laser-light scattering event that arises from instrumental causes rather than from any feature on or near the wafer surface; also called false positive; compare nuisance count. [ASTM Practice F 1620]

5.4.1 *Discussion* — False counts would not be expected to occur at the same point on the wafer surface during multiple inspection scans, and hence they could be considered as random "noise" that could be identified by examining the results of repeated scans.

5.5 *false count rate (FCR)* — the mean total number of false counts per wafer that an SSIS reports at some specified SSIS operational setting.

5.6 *repeat counts* — LLSs that are found in a later scan within the scanner *XY* uncertainty distance of their location as found on an earlier scan.

5.6.1 *Discussion* — The implication is that if defect density is low enough, then a repeat count results from detecting the same LLS event again and is not the result of SSIS noise. Besides the absolute position of the LLS, an additional matching condition may be the LSE signal of the LLS.

5.7 *scanner* XY *uncertainty* — The quadrature sum of the one-sigma uncertainties in the *X* and *Y* location uncertainties of the SSIS under test.

5.7.1 *Discussion* — In ASTM Practice F 1621, this quantity is called positional accuracy and is determined under a variety of experimental conditions. For purposes of the present test method, the scanner *XY* uncertainty should be determined under static repeatability condition, i.e., without removing the wafer from the stage between scans.

5.8 *standard reference material (SRM®)* — A certified reference material (CRM) issued by the U.S. National Institute of Standards and Technology (ASTM Guide F 1527).

5.9 *true count* — a laser-light scattering event that arises from the localized light scatterers (LLS) being investigated. [ASTM Practice F 1620]

6 Summary of Method

6.1 The *XY* coordinate uncertainty of the scanner is determined under static repeatability conditions.

6.2 The reference wafer to be used in this test is selected.

6.3 The selected wafer is scanned *Z* times on the SSIS under test. The first two scans are used to qualify the reference wafer before continuing with the remaining *Z*–2 scans.

NOTE 3: Typical values for *Z* are between 30 and 100 scans.

6.4 The scans are analyzed to determine and record the number of times each LLS event occurs in each location (to within a distance approximately six times the scanner *XY* uncertainty) during the *Z* scans. The capture rate, standard size deviation, false count rate, and cumulative false count rate are determined from this data set.

7 Apparatus

7.1 *The SSIS under test* should be installed in its position of use with clean room rating recommended by the manufacturer

7.2 *Off-line analysis software program* — to track each observed count and determine the capture rate, standard size deviation, the number of false counts at each LLS size, the false count rate, and the cumulative false count rate.

NOTE 4: The analysis software may be incorporated into the SSIS, if desired.

8 Test Specimens

8.1 Use any wafer with (1) natural LLS with density of LLS < 10 LLS/cm^2 and (2) a surface roughness typical of the wafers to be measured in production (see Section 2.3).

8.1.1 The minimum distance between any two LLS found during any one scan and used in the data set to be analyzed shall be larger than six times the scanner *XY* uncertainty. Clusters of LLS (found in any one scan and closer together than six times the scanner *XY* uncertainty) and scratches must be excluded during the analysis.

8.1.2 Determine the scanner *XY* uncertainty from previous knowledge, from the scanner manufacturer specifications, or from the positional accuracy determined under static repeatability conditions in accordance with ASTM Practice F 1621.

8.2 Alternatively, a wafer with deposited polystyrene latex spheres can be used to more accurately evaluate the capture rate at a specific particle size. The same particle density, particle spacing, and defect cluster conditions as in Section 8.1 should be observed.

NOTE 5: The wafer with deposited PSL spheres may or may not be an SRM or other certified reference material.

9 Procedure

9.1 Qualify the wafer for appropriate LLS number (see Section 8.1) prior to taking CR and CFCR data as follows:

9.1.1 Scan the wafer once and determine position, P_m, and size, $S_{m,}$ of each of the M_1 detected LLS_m events with $m = [1, M_1]$.

9.1.2 Scan the wafer a second time and compare the detected LLS events with respect to the positions of those detected during the first scan. The total number of LLS events that repeat their position in the first scan to within six times the scanner *XY* uncertainty is defined as M_2. To qualify the wafer, the share of repeat LLS events on the wafer, M_2, shall be larger than 0.75 M_1. The conditions of Sections 8.1 and 8.1.1 must be fulfilled for both wafer scans. The purpose of this scan is to determine that there are enough repeating LLS events to make the CR calculation meaningful.

9.2 Scan the wafer a total of *Z* times to obtain CR, FCR, and CFCR data. (See NOTE 3.) The two scans of Section 9.1 can be used as part of this data set; however, the wafer must remain on the scan stage during the entire set of *Z* scans to perform a static measurement sequence. Record each LLS event detected during the *Z* scans according to its position, *P* and size, *S*.

10 Analysis

10.1 *Initial Analysis*

10.1.1 Determine the locations on the wafer where an LLS event has been detected at least once by comparing all recorded positions (within the constraint of the six-sigma *XY* uncertainty) of the multiple scans as reported by the SSIS. These locations, L_i, with $i=[1,N]$ represent the complete set of LLS events which will be used in the further analysis. Each location is characterized by the number of scans H_i, in which the LLS event at that position has been detected, and by the H_i reported sizes S_{ih}, where $h=[1,H_i]$, for the LLS event.

10.1.2 Consider those of the *N* events with $H_i = 1$, (i.e., events seen only once) as false counts. Order these events by decreasing size, S_i. Index them by $f = [1,F]$, with $f = 1$ representing the largest size and $f = F$ representing the smallest.

10.1.3 Consider those events that were seen at least twice during the Z scans ($H_i \geq 2$) to be true counts.

NOTE 6: The sequence of analysis steps given below is intended to be representative and illustrative. The actual algorithms used in the analysis software may differ from these as long as the same result is achieved.

10.2 *Analysis of True Counts*

10.2.1 Determine the average size $<S_i>$ of each true count ($H_i \geq 2$) as follows:

$$< S_i > = \frac{1}{H_i} \sum_{h=1}^{H_i} S_{ih}$$

10.2.2 Calculate the size dependent capture rate, $CR(<S_i>)$, for every true count as follows:

$$CR(< S_i >) = \frac{H_i}{Z}$$

10.2.3 Plot $CR(<S_i>)$ versus $<S_i>$ as in the example in Figure 1, and interpolate or fit the data to discriminate against outlying points.

NOTE 7: The following equation for $c_{s,}$ in percent,

$$c_s = 100 \left[1 - \exp\left(\frac{s_0 - s}{c_0}\right)\right],$$

may be used to fit the plotted $CR(<S_i>)$ data. Here, c_s is the fitted value of $CR(<S_i>)$, s is the size ($<S_i>$), s_0 is the size at zero probability of capture, and c_0 is a curvature factor that determines the point at which the probability of capture approaches 100%. As c_0 and s_0 constitute a sufficient parameter set to describe completely $CR(<S_i>)$, they can be used for reporting, together with the chi-square goodness of the fit test statistic result.

10.2.4 Calculate the standard deviation of size, S_i for all true counts as follows:

$$\sigma(S_i) = \sqrt{\frac{1}{H_i - 1} \sum_{h=1}^{H_i} (S_{ih} - < S_i >)^2}$$

10.2.5 Plot the standard deviation of size, $\sigma(S_i)$, versus the mean size, $<S_i>$, for all true counts as shown in the example in Figure 2.

10.3 *Analysis of False Counts*

10.3.1 Divide the total number of false counts, *F*, by the number of scans, *Z*, to get the false count rate, *FCR*:

$$FCR = \frac{F}{Z}$$

10.3.2 Analyze the false count rate as a function of size to determine the cumulative false count rate, $CFCR(S_i)$, at each size, S_i, by taking the total number of false counts of size equal to or greater than S_i, and dividing by the number of scans, *Z*:

$$CFCR(S_i) = \frac{F_i}{Z},$$

where F_i is the largest value of the index associated with the count (or counts) of size S_i.

10.3.3 Plot $CFCR(S_i)$ as a function of S_i as shown in the example in Figure 3.

11 Report

11.1 Report the following information:

11.1.1 Operator identification;

11.1.2 Date of test;

11.1.3 Manufacturer, model, serial number, and software version of the SSIS being tested,

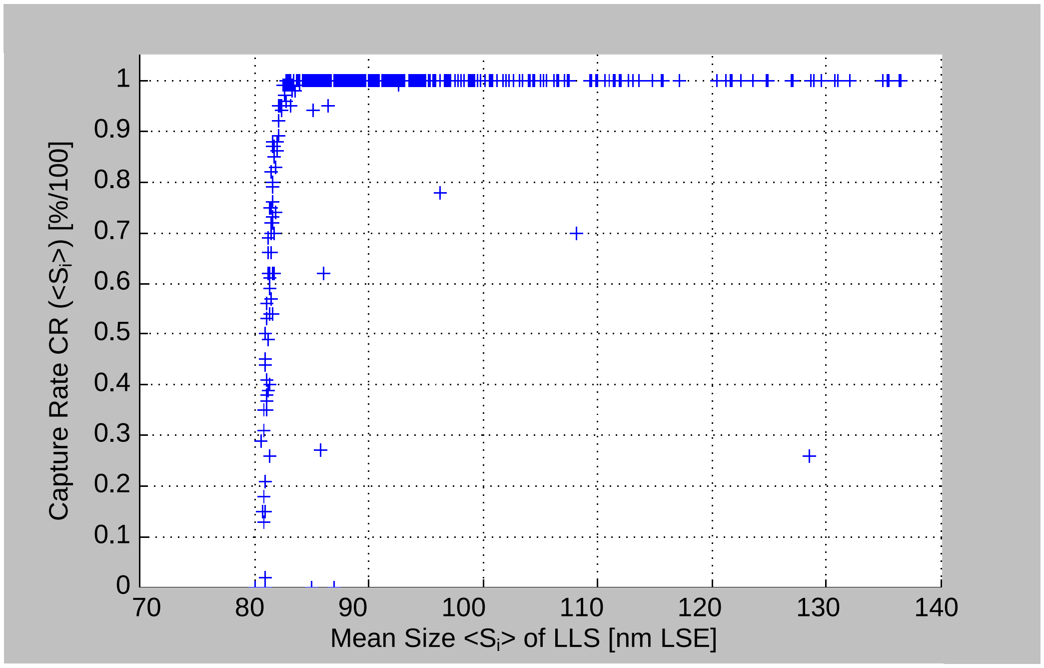
11.1.4 Description of the reference wafer used in the test.

11.1.5 Plot of the capture rate, $CR(<S_i>)$, *vs.* the mean size, $<S_i>$, similar to the example in Figure 1.

11.1.6 Plot of the standard deviation, $\sigma(S_i)$, of the LLS mean size, $<S_i>$, similar to the example in Figure 2.

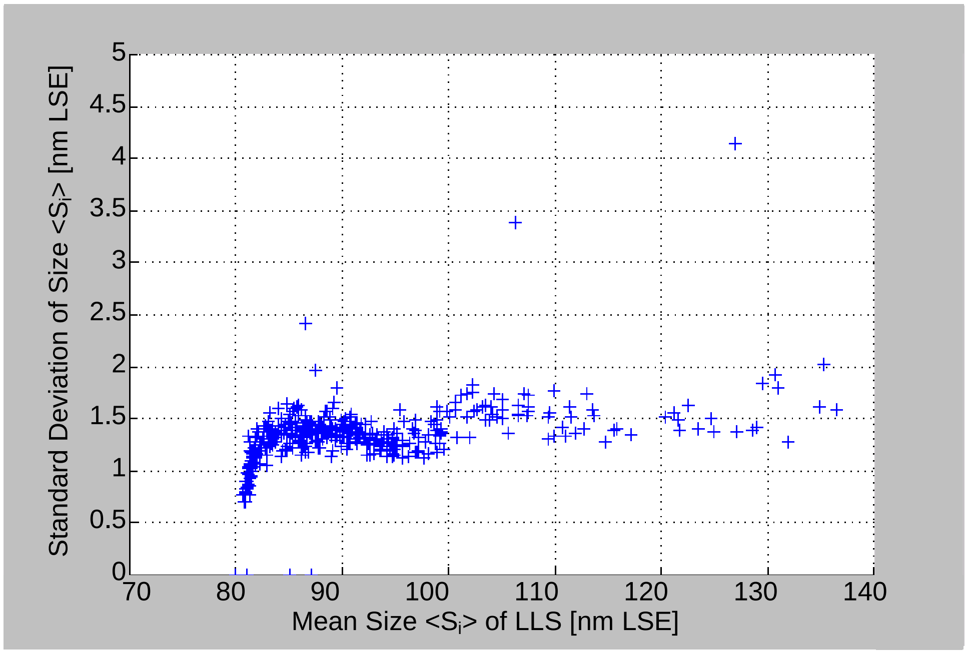
11.1.7 Calculated false count rate, *FCR*, as described in Section 10.3.2.

11.1.8 Plot of the cumulative false count rate, $CFCR(S_i)$, similar to the example in Figure 3.



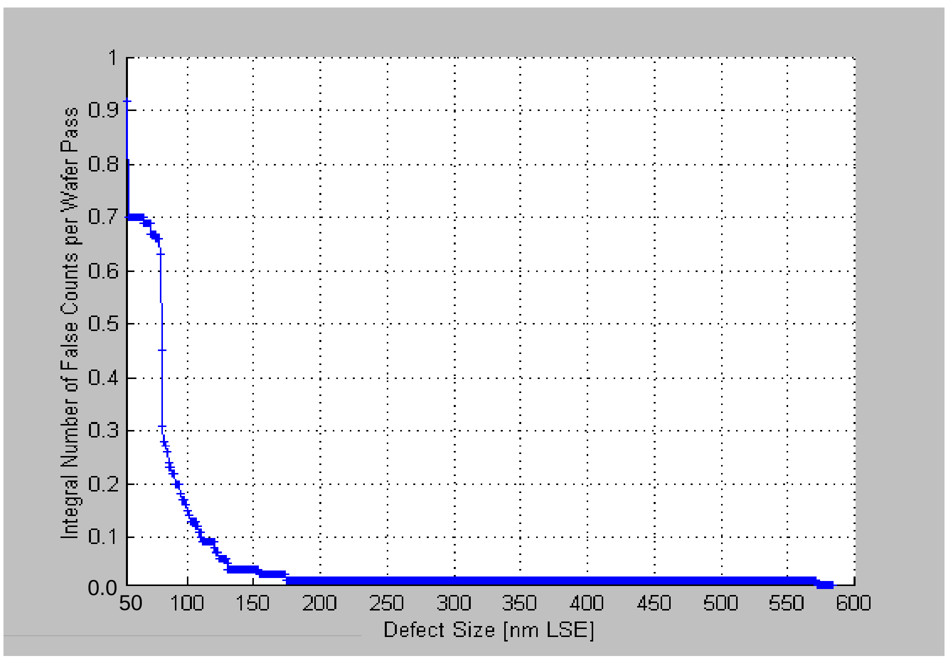
NOTE 1: This figure is an example plot of capture rate as determined in Sections 10.2.1 through 10.2.3. The measurements in this example are the result of 100 scans on a wafer with several natural LLS sites of different sizes. The SSIS noise floor was set at 80 nm LSE.

Figure 1
Capture Rate



NOTE 1: This figure is an example plot of the standard deviation of true count size as determined in Sections 10.2.4 and 10.2.5.

Figure 2
Standard Size Deviation



NOTE 1: This figure is an example plot of cumulative false count rate as determined in Sections 10.3.1 through 10.3.4 This is the same data set used for Figures 1 and 2; however, the horizonatal scale has been expanded.

Figure 3
Cumulative False Count Rate (CFCR)

SEMI M51-0702
TEST METHOD FOR CHARACTERIZING SILICON WAFER BY GATE OXIDE INTEGRITY

This test method was technically approved by the Global Silicon Wafer Committee and is the direct responsibility of the Japan Silicon Wafer Committee. Current edition approved by the Japan Regional Standards Committee on April 26, 2002. Initially available at www.semi.org June 2002; to be published July 2002.

1 Purpose

1.1 Technique outlined in this standard is for the purpose of standardizing silicon wafer characterization by Gate Oxide Integrity (GOI). For a more detailed discussion of the general characterizing methods for this test, the reader is referred to Section 3. This test method is effective to evaluating Crystal Originated Particles in polished Si wafers that influence GOI.

2 Scope

2.1 This standard is for the purpose of characterization method of silicon wafer by GOI. This characterization method outline is below.

1) MOS (Metal-Oxide-Semiconductor) – capacitors fabrication: On the silicon wafer surface, a gate oxide film is thermally grown. Next, poly-Si electrodes are formed on the gate oxide film.

2) Electrical characterization: TZDB (Time Zero Dielectric Breakdown) characteristics of the MOS capacitors are measured. The presence of COP (Crystal Originated Particles) in the polished Si substrates gives an influence of the TZDB histogram of the gate oxide. That is, the silicon wafer is characterized by such GOI methods. The technique outlined in this standard is for the purpose of standardizing the procedure of MOS fabrication, measurement, analysis, and reporting of GOI data to interested parties. This standard is based on round robin results among the silicon wafer manufacturers. In general, this GOI test strongly depends on wafer surface/near–surface crystal defects, contaminations, particles, fabrication processes, and so on. Clean environment in which the MOS capacitors are fabricated shall be evaluated to be acceptable (see Section 5.2.1 and Related Information 1).

2.2 A target of this standard is to characterize silicon wafer. A proper gate oxide thickness of the MOS sample is 20–25 nm. Discussion of the gate oxide thickness is given in later section. It is well known that oxygen precipitate is also one of the gate oxide defect origins[1]. But, this is out of discussion of this standard, because the as-received wafers contain only a little oxygen precipitate.

2.3 The poly-Si film is used as a gate electrode of measured MOS capacitors. The poly-Si film can make standard test results fitter in actual integrated circuits than other metal electrodes because the poly-Si electrode is quite commonly used in most of the actual devices. It is advisable that a poly-Si electrode thickness range is from 200 to 400 nm, and a sheet resistivity range is less than 50 ohm/sq. (These poly-Si condition is discussed in later section.)

2.4 For a detailed discussion of sample structures for this test method, the reader is referred to EIA/JEDEC Standard 35-1. In general, the three most likely sample structures are simple planner metal-oxide semiconductor (MOS) capacitors, various isolation structures (for example, local oxidation of silicon (LOCOS), shallow trench isolation (STI)), and field effect transistors (FET). For the purpose of silicon wafer characterization, the simple planner MOS capacitor structure is most desirable. In the case of the various isolation structures and FET, the silicon wafer receives thermal treatments some times in the complicated sample fabrication process. Therefore, it is questionable that we look upon this measurement as the starting Si wafer characterization.

2.5 This TZDB method measure oxide breakdown electric fields using MOS capacitors. (The measurement condition gives the details later.) The COP influence on the oxide breakdown can be estimated by histogram of breakdown electric field.

2.6 The gate voltage is negatively biased so as to be in accumulation the Si surface and be effectively applied to the gate oxide. The applied electric field is stepwise increased from 0 to 15 MV/cm (in case of 25 nm gate oxide thickness: actual applied voltage is from 0 to 37.5 V).

1 K.Yamabe and K.Taniguchi, "Time-Dependent Dielectric Breakdown of Thin Thermally Grown SiO_2 Films", J. Solid St. Circuits, SC-20, 343(1983).

2.7 This test method is applicable to p-type CZ polished Si wafers. In the case of n-type Si wafer, the applied voltage polarity is reversed.

2.8 This standard does not purport to address safety concerns, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability or regulatory limitations prior to use.

4 Terminology

4.1 *Abbreviations and Acronyms*

4.1.1 *COP* — Crystal Originated Particles

4.1.2 *GOI* — Gate Oxide Integrity

4.1.3 *LOCOS* — Local Oxidation of Silicon

4.1.4 *MOS* — Metal Oxide Semiconductor

4.1.5 *STI* — Shallow Trench Isolation

4.1.6 *TZDB* — Time Zero Dielectric Breakdown

4.2 *Definitions*

4.2.1 Many terms relating to silicon technology are defined in ASTM Terminology F 1241.

4.2.2 Definitions for some additional terms are given in SEMI M1 and ASTM F1771.

4.2.3 Other terms are defined as follows:

4.2.3.1 *crystal originated particles*[5] *(COP)* — This is the one of grown-in defects in the CZ Si wafers with an octahedral structure. This was found as particles

5 J. Ryuta, E. Morita, T. Tanaka and Y. Shimanuki, “Crystal – Originated Singularities on Si Wafer Surface after SC1 Cleaning”, *Jpn. J. Appl. Phys*. 29(1990) L947.

appeared on the silicon surface by repetition SC-1[6] of RCA cleaning.

4.2.3.1.1 *Discussion* — It has been thought that the COP is one of the main origins of the GOI degradation. The gate oxide formed on the Si surface at which the COP appears easily breaks down at the corner of the octahedral shape like at a Si trench corner[7,8]. This corner of octahedral structures is thinning the oxide films. The oxide electric field enhances at that place. The breakdown electric field is decreased.

4.2.3.2 *failure modes* — The breakdown failure results are summarized in terms of ranges of oxide electric field in which the breakdown occurred. One set of categories (A, B and C for TZDB) widely used[9, 10] is as follows:

- *A mode failure*: 0 MV/cm $\leq E_{bd} <$ 3 MV/cm
- *B mode failure*: 3 MV/cm $\leq E_{bd} <$ 8MV/cm
- *C mode failure*: 8 MV/cm $\leq E_{bd}$

4.2.3.2.1 *Discussion*

- *A mode failure*: Initial short

  This failure mode is caused by pinholes of oxide films formed in the gate oxide process. The COP does not cause these oxide pinholes.

- *B mode failure*: Accidental breakdown

  The COP is a main origin of this failure. This failure mode gives influence on MOS devices or MOS integrated circuits.

- *C mode failure*: Fatigue breakdown

  This failure mode is partly caused by the COP, but is almost wearout breakdown. These categories have traditionally been used for oxide thickness about 20–25 nm. For thinner films, care must be taken in their use and in proper derivation of the oxide filed strength as described in RELATED INFORMATION 1.

4.2.3.3 *Time Zero Dielectric Breakdown (TZDB)* — This is one of the electrical characteristics of dielectric films. This characteristic is contrasted with time dependent dielectric breakdown[11,12].

4.2.3.3.1 *Discussion* — An applied bias, for which the oxide leakage current goes over a predetermined I_{bd}, is measured as a breakdown gate voltage. The breakdown electric filed is defined by the gate breakdown voltage normalized by the gate oxide thickness.

5 Summary of Method

5.1 *Overview* — This test method are fabricating array of the many similar MOS capacitors on silicon wafers, measuring the TZDB voltage histogram by applying step voltage to the MOS capacitors with monitoring the oxide leakage current, estimating the dielectric breakdown defect density which is caused by silicon wafers. The defect density is estimated from the B-mode failure fraction. This test method is to characterize the Si wafer and is very useful in the crystal defect (mainly COP) evaluation of mirror polished CZ Si wafer.

5.2 *MOS Capacitor Fabrication Process* — Many MOS capacitors are formed on the test wafer. The MOS fabrication process consists of wafer cleaning, thermal oxidation, poly-Si deposition, phosphorous doping, activation heat treatment, photolithography and etching.

5.2.1 *Fabrication Environment* — It is necessary to fabricate MOS capacitors in the clean room environment of 1000 or better class in total quality. That is, it needs to be confirmed that the A mode failure rate is 10% or less. The A mode failure depends not only on the particle of work environment atmosphere but also on the ultra pure water, fixtures, process apparatus, clean cloths, operation rules etc. Heavily contamination such as alkaline or heavy metal has an important effect on the TZDB of the oxide.

5.2.2 *Wafer Cleaning* — To characterize the as-received Si wafers, the wafers shall not be cleaned. If it might contaminate a furnace, the wafers shall be cleaned before oxidation. In these cases, the wafers are cleaned by a modified RCA method[6], in general. The cleaning method shall be confirmed in advance that the previously mentioned condition for the A mode failure is met.

12 E. S. Anolick and G. R. Nelson, "Low Field Time Dependent Dielectric Integrity", Proc. *Int. Reliability Physics Symposium*, 1978, p.8

5.2.3 *Thermal Oxidation* — The gate oxide of the MOS capacitor is thermally grown. It is desirable to fix the oxidation conditions. Because the oxidation rate is influenced to oxidation temperature[13] and the gate oxide quality is depend on the oxide film thickness[9] and, strictly speaking, oxidation condition (ambient, temperature etc.). It is recommended that the gate oxide of about 20–25 nm thick is grown in dry oxygen ambient at 850–950°C. It is possible that addition of HCl or water vapor to the oxidation ambient leads to underestimate the oxide defect density. As the result, one evaluation result of the gate oxide formed in a special oxidation condition cannot be compared with that in the standard oxidation condition. To measure an oxide film thickness, a monitor wafer is oxidized with sample wafers. An average value of 5 or more points on the monitor wafer is adopted as the oxide thickness.

5.2.4 *Electrode Formation* — The poly–Si layer with a thickness of 200 nm–400 nm and a sheet resistance of 20–50 Ω/sq is formed by low-pressure chemical vapor deposition (LPCVD). In general, there are two type phosphorous doping methods. One is ex-situ doping, and another is in-situ doping.

5.2.4.1 *Ex-situ Phosphorous Doping* — After the undoped poly-Si film is deposited by the LP-CVD method, phosphorus is diffused using $POCl_3$ as a phosphorous source.

5.2.4.2 *In-situ Phosphorous Doping* — The phosphorous-doped poly-Si is deposited using an in-situ doping LPCVD, following a heat treatment to activate the doped phosphorus.

5.2.5 *Discussion* — Too high resistance of the poly-Si electrode films leads a voltage drop within the electrode not to be neglected. That is, in the case, the oxide leakage current is decreased in the range of the higher electric field. On the other hand, too low resistivity of them caused by higher concentration phosphorous doping leads the gate oxide dielectric characteristics to degrade. Too thin poly Si electrode leads self-healing of the oxide weak spots to be easier[9]. The self-healing makes us underestimate the oxide breakdown defect density. Too thin poly-Si electrode leads the TZDB measurement to degrade for mechanical stress of an exploring probe such as tungsten. Too thick poly-Si electrode in the ex-situ doping technique is easy to induce a depletion layer of phosphorus near the poly-Si/SiO_2 interface that causes parasitic resistance and unnecessary voltage drop in a measurement circuit. It is desirable to monitor poly-Si thickness and sheet resistance of the poly-Si layers every processing batch using a monitor wafer.

13 B.E.Deal and A.S.Grove, "General relationship for the thermal Oxidation of Silicon", J.Appl.Phys., 36, 3770(1965).

5.2.6 *Photolithograph Process* — The electrodes of the MOS capacitors are formed by patterning in the photolithograph. EIA/JEDEC Standard 35-1 is referred to about this mask design. The appropriate area and the appropriate number of the MOS capacitors for each defect density shall be selected to detect the crystal defect with a high sensitivity. For the evaluation of COP, it is necessary to measure 100 or more MOS capacitors with a gate area of 10 mm^2 on a wafer. (See Table R1-3 in Related Information 1.) It is desirable to prepare the plural of MOS capacitors of the same area within each chip as a spare.

5.2.7 *Etching Processes* — The photo resist pattern formed by photolithograph technique is used as the mask of poly-Silicon etching. Generally a wet etching method or a dry etching method is applied for poly-Silicon etching. If the wet etching method is applied, the etching rate shall be controlled well. If the peripheral oxide of the electrode is removed, it is sometimes difficult to accurately measure the TZDB. If the dry etching method is applied, especially RIE, charging-up of MOS capacitor shall be cared. In the case that the A mode defect density is high, the MOS capacitors shall be confirmed to not be charged up during the etching process. If an ashing removal of the photo resist is applied, the charging-up of MOS capacitor shall be cared. Similarly to RIE, in the case that the A mode defect density is high, the MOS capacitors shall be confirmed to not be charged up during the ashing process. If there an oxide and the poly-Si film on the wafer backside surface, those shall be removed.

5.3 *Measurement of Electric Characteristic of MOS Capacitors*

5.3.1 The dielectric breakdown defect density of the silicon oxide is evaluated by the TZDB method for the MOS capacitors. In the TZDB method, the gate oxide electric field of MOS capacitor is kept increasing in step. The electric field applied to the gate oxide when the gate oxide leakage current exceeds the predetermined dielectric breakdown judgment value is defined as the oxide dielectric breakdown field. From a histogram of the breakdown field for the 100 or more MOS capacitors, the dielectric breakdown defect density is estimated.

5.3.2 We can see two characteristics of the formed MOS capacitors from the current-voltage (IV) plots. First, deviation of the gate oxide thickness appears in a loose distribution of the IV plots. Second, if the I-V curves bend suddenly and have gentle slope in the high voltage region, there may be the high parasitism resistance, for example, the high resistance of the poly-Si electrode. In such a case, the low reliable measurement demands the adjustment of the MOS preparation process.

5.3.3 *Applied Step Voltage*

5.3.3.1 For the reliable measurement, a voltage resource with well-defined output shape shall be used. An overshooting of the applied step voltage decreases the apparent oxide breakdown voltage as compared with a real breakdown voltage. In the TZDB measurement, the oxide leakage current is measured after holding the constant applied voltage during a predetermined time. After then, the applied voltage increases stepwise. This procedure is repeated. If the holding time is shorter than 100 ms, the stability of the voltage may be not enough for the current measurement. And if the hold time is longer than 800 ms, the stability of the voltage may be enough. Especially, in the high electric field region, the gate oxide may receive the electric stress similar to time dependent dielectric breakdown (TDDB). The holding time of 200 ms is recommended. Accordingly to the round robin result as described in RERATED INFORMATION 1, there are no problems in setting the holding time of 100–800 ms. A recommended step height of the applied voltage is between 0.1–0.5 MV/cm in electric field. The polarity of the voltage is selected for the Si surface so as to be in accumulation. That is, for P type silicon wafer, the gate oxide is negatively applied. The maximum electric field is 15 MV/cm. Even if the gate voltage corresponding to more than 15 MV/cm is applied, the voltage is not affectively applied to the gate oxide because of the voltage drop at the parasitic resistance.

5.3.4 *Breakdown Judgment*

5.3.4.1 The oxide dielectric breakdown is judged by the predetermined oxide leakage current. That is, when the gate oxide leakage current exceeds the dielectric breakdown judgment current, the applied voltage is defined as the breakdown voltage. The breakdown electric field is the value that the breakdown voltage is normalized by the gate oxide thickness.

5.3.4.2 *Discussion* — If the dielectric breakdown judgment current is too high (Ig > 10–3A), one part of proper A-mode failures can be counted as the B-mode failure because of the series resistance of the samples or measurement system. Otherwise, if the judgment current is too low (Ig < 10–7A), one part of proper C-mode failures that the gate oxide was not broken down is counted as the B-mode failure. In both cases, it will be done to take a mistake in classification of the failure mode categories, even if the measurement is accurately done and appropriate I–V curves is gotten. So the dielectric breakdown judgment current of 10–5A is recommended.

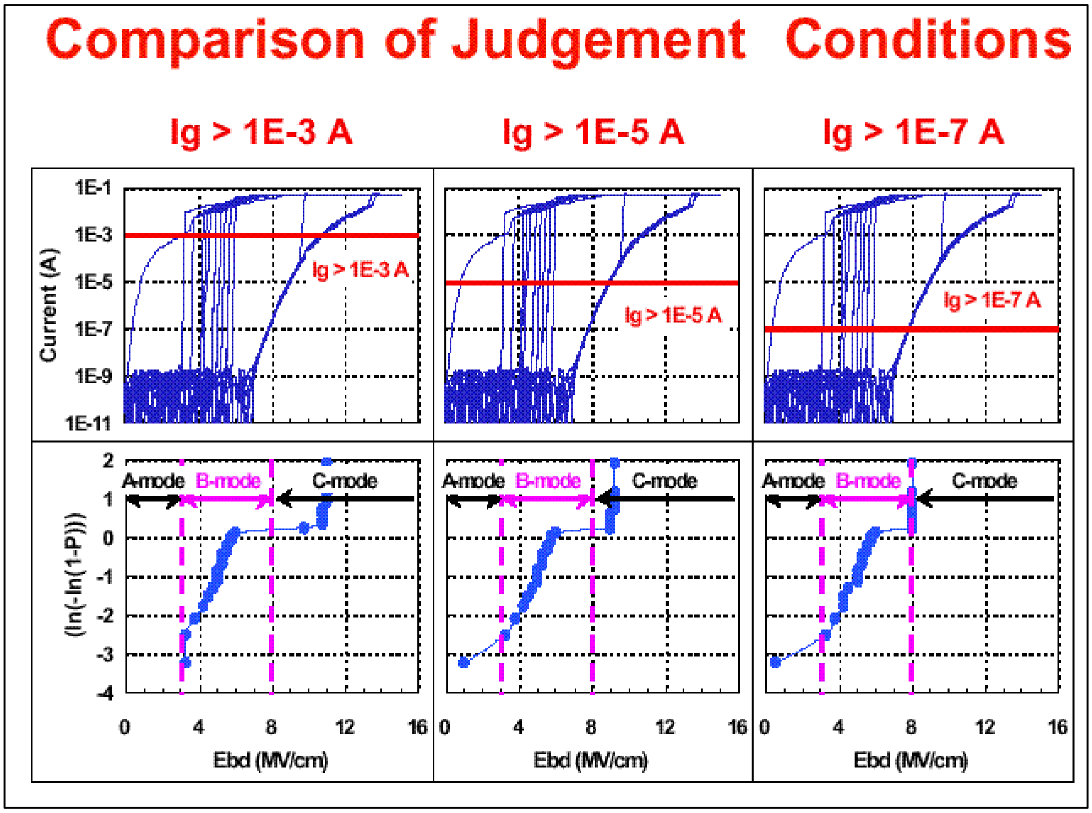

Figure 1
Comparison of Judgment Conditions

6 Significance and Use

6.1 This standard gives instructions for the procedure to characterize mirror polished CZ-grown p-type Si wafers by measuring the dielectric breakdown defect density in the thermally grown gate oxide film of the MOS capacitors. The MOS capacitors must be formed in accordance with the preparation process described in Section 5 that influences the oxide characteristics.

6.2 It is well known that both the Si surface morphology and the cross-sectional structure at the pattern edge of the active region/field isolation region of MOS devices influences the dielectric breakdown of the gate oxide. Various kinds of contaminations also influence the dielectric breakdown of the gate oxide. The contamination such as the alkaline or heavy metal and the organic particles increases with increasing sample fabrication process steps. Furthermore, the COP increases with SC-1 cleaning step numbers. These facts indicate that it is desirable to simplify the sample structure and its preparation processes to characterize the proper Si wafer by the TZDB of the gate oxide. Thermal process can cause oxygen precipitate growth in a Si wafer. This standard cannot be applied to Si wafers that might receive such a thermal process.

6.3 The appropriate area and the appropriate total number of the tested MOS capacitors shall be chosen so as to answer the purpose of this standard test. For example, as shown in Table R1-3 of RELATED INFORMATION, it is suitable to select the gate electrode area of 10 mm^2 and the total capacitor number of more than 100.

6.4 The electrode of the MOS capacitors has a great influence on the dielectric breakdown of the gate oxide. Poly-silicon is recommended as the electrode material in this standard. It is applicable to practical ultra large-scale integrated circuits (ULSI). The poly-Si electrode gives us test results highly consistent with the actual ULSI.

7 Interferences

7.1 Since this is a DC measurement, care must be taken to make sure that the Si wafer has a low resistance ohmic contact. There must be no dielectric film on the backside surface, e.g. silicon oxide, in order to effectively apply a voltage bias to the gate oxide. This is not necessary to be done with a metallic contact to the backside of the wafer under test.

7.1.1 However, when the vacuum chucking is weak, care must be taken on a possibility that the dielectric breakdown voltage of the gate oxide cannot be accurately measured due to the increase in the parasitic resistance.

7.2 It is strongly suggested that testing be done with a voltage polarity that the Si surface will be in accumulation underlying the gate oxide, that is, negative voltages for the p-type Si wafers. If the polarity of the voltage is chosen to be in the reverse direction, the accurate breakdown voltage may not be measured due to presence of a depletion layer below the gate electrode.

7.3 Evaluation and control of electrical noise in the current-voltage data as part of this test method are crucial to the proper identification of the failure criteria.

7.4 In the TZDB measurement, lowering of the electrical noise under low bias stress condition is made possible by averaging of measurement data using a sampling function of the measurement system. While the required 100-ms holding time may be set using a delay in the measurement loop, an additional, uncontrolled delay may be incurred due to autoranging of an electrometer. The effect is most pronounced for very low oxide leakage currents, where the measured value is several orders of magnitude below the minimum range set by the electrometer software.

7.5 Too high mechanical stress of the exploring probe can influence the measurement results, because the exploring probe is directly contacted to the gate electrode on the gate oxide.

7.6 The actual results obtained will depend somewhat on the sample fabrication process. Care must be taken to ensure a consistent processing.

7.7 Wafer temperature during testing shall be clearly defined. While the dielectric breakdown voltages are not strongly temperature-dependent, the oxide wearout mechanism is temperature-sensitive, and large temperature variations might have an impact on results.

7.8 Precaution: Since the voltage and currents involved are potentially dangerous, appropriate means of preventing the operator from coming into contact with the exploring probe or other charge surfaces shall be in place before testing.

7.9 This standard does not include any clauses relating to safety and sanitation of the environment. Those who intend to implement this standard shall consider appropriate means to prevent any accidents or disasters, as well as taking responsibility for maintaining a state of safety, health and hygiene for users.

8 Apparatus

8.1 The MOS capacitors shall be fabricated in an environment of 1000 or better class in total quality to prevent various contaminations. Contamination control in the processes from wafer cleaning step to poly-Si deposition step are especially important. The contaminations in those processes have been reported to degrade GOI. Therefore, attention must be paid particularly to these processes.

8.2 High purity deionized water and high purity chemicals of the electronics industry grades shall be used in the processes of wafer cleaning, wet etching, etc.

8.3 In thermal processes such as gate oxidation, poly-Si deposition and phosphorus doping, the fluctuation of process temperature may affect the uniformity of oxide thickness, poly-Si thickness and concentration and distribution of doped phosphorus ions. The temperature fluctuation of used furnaces shall be within ± 5°C at least.

8.4 Quartz is very stable for the strong acids excluding hydrofluoric acid or the strong alkalis used in the wet processes and at higher temperature than 1000°C. Therefore, quartz vessels and tubes, and so on are quite frequently used in the ULSI manufacturing processes. The quartz vessels and tubes with high purity of the electronics industry grades shall be also used in this MOS capacitor fabrication processes.

8.5 High purity gases of the electronics industry grades, such as N_2, O_2 and SiH_4, shall be used in the processes of the thermal oxidation, the poly-Si deposition, the phosphorous doping and so on to prevent contamination from the gases.

8.6 A criterion judging the validity of a clean room environment where the MOS samples is fabricated for this test method is that the A-mode failure fraction of the samples with 20–25 nm oxide is less than 10%. It is advisable that a cleanness level of the clean room environment where the tested MOS capacitors are fabricated is evaluated by the TZDB measurement of the MOS capacitors on an epitaxial wafer.

8.7 ASTM standard F1771 shall be applied for the measurement equipment such as voltage source units and manual probing machines.

9 Sampling

9.1 Sampling is the responsibility of the user of this test method. However, if testing is done as part of comparison or correlation, all participants shall agree upon sampling in advance.

NOTE 2: Refer to the appendix of JEDEC standard No.35 for good discussion of sampling plan statistics.

10 Procedure

10.1 *Fabrication of MOS Capacitor*

10.1.1 It shall be confirmed first that the environment for fabricating MOS capacitors is suitable for this test method. The environment includes clean room, chemicals, ultra pure deionized water, oxidation furnace, poly-Si deposition equipment, different kinds of quartz jigs, etc. As a criterion, A-mode failure fraction of MOS capacitors made in the environment shall be less than 10%.

10.1.2 To characterize the proper Si wafers, the wafers shall not be cleaned. If the wafers might contaminate a furnace, they shall be cleaned before oxidation. In these cases, the wafers are cleaned by a modified RCA method[6], in general.

10.1.3 Input oxidation parameters to a used furnace system. The parameters include oxidation temperature, ambient, gas flow rate, oxidation time, etc. A recommended oxidation temperature is 850–950°C. The appropriate parameters to obtain the recommended oxide thickness (20–25 nm) shall be found out in advance by preliminary tests.

10.1.4 Oxidize the wafers in dry oxygen ambient. Some reference wafers shall be treated with the sample wafers to monitor oxide thickness and sheet resistance of a poly-Si electrode later. The number of reference wafers shall be decided by user of this test method taking account of the quantity of the total wafers in the batch.

10.1.5 Measure an oxide thickness of the reference wafers by ellipsometry (or other optical method) to confirm a uniformity of the oxide thickness within a wafer. Average thickness shall be in 20–25 nm and the dispersion within a wafer shall be less than ± 3%.

10.1.6 Input deposition parameters of poly-Si to a used LP-CVD furnace system. The parameters include deposition temperature, pressure, gas flow rate, deposition time, etc. The appropriate condition to obtain the recommended poly-Si thickness (200–400 nm) shall be found out in advance by preliminary tests. If a doped poly-Si film will be deposited, corresponding deposition parameters shall be input.

10.1.7 Deposit a poly-Si film on the wafers oxidized. The recommended deposition temperature from this test method is 570–640°C. Some reference wafers with an oxide shall be treated with the sample wafers to monitor the poly-Si thickness later. The oxide thickness on the reference wafers shall be recommended by a vendor of equipment to measure a poly-Si film thickness. The number of reference wafers shall be decided by a user of this test method taking account of the total wafer quantity in the batch.

10.1.8 Measure poly-Si thickness on the reference wafers using spectroscopic reflectometer (or other optical film thickness measurement instruments) to confirm the uniformity of poly-Si film thickness within a wafer and within a batch. Average poly-Si film thickness shall be in 200–400 nm and dispersion within a batch shall be less than ± 10%. If doped poly-Si was deposited, proceed to Section 10.1.11.

10.1.9 Input the doping parameters to a phosphorus-doping furnace system. The parameters include doping temperature, ambient, phosphorous source, carrier gas flow rate, doping time, etc. $POCl_3$ is a well-known phosphorous source. Those process parameters will affect poly-Si resistance and its uniformity. The appropriate process parameters to obtain a recommended sheet resistance (20–50 Ω/sq) shall be found out in advance by preliminary tests.

10.1.10 Dope phosphorus into the poly-Si film on the Si wafers. The reference wafers shall be doped with the sample wafers to check the poly-Si film resistance.

10.1.11 Measure sheet resistance of reference wafers using resistance meter to confirm a uniformity of resistance within a wafer and within a batch. Average resistance shall be 20–50 Ω/sq and the dispersion within the batch shall be less than ± 10%.

10.1.12 Make a resist mask pattern using photolithography technique. The recommendation for gate electrode pattern of the MOS capacitors in this test method is to form more than 100 capacitors with an area of 10 mm^2 within a wafer.

10.1.13 Etch the poly-Si film to form MOS capacitors. At the same time, the backside poly-Si film shall be etched. If a dry etching method is used, care must be taken to avoid plasma damage on the formed MOS capacitors.

10.1.14 Etch the backside oxide. Care must be taken to prevent damage on MOS capacitors in the etching process. For example, a coating resist on the front surface can prevent the gate oxide from sustaining damage in NH_4F etching.

10.1.15 Remove the resist on the sample Si wafers. If a plasma ashing machine is used, attention must be paid because some kind of the ashing machine was reported to damage MOS capacitors.

10.2 *Measurement*

10.2.1 Before the measurement, record the following information for each sample: date, time, operator, sample ID, oxide thickness, gate area, gate material, oxidation condition, conductivity type (p or n), equipment ID, and comment.

10.2.2 Decide measurement parameters and record them. Stepwise voltage is applied in this test method. The parameters include maximum stress voltage (V_{max}), increment of step voltage (ΔV), step hold time (T_h), judgment current of breakdown (I_{bd}), measurement temperature, the number of capacitors to be measured and a map of the capacitors.

10.2.3 Set a tungsten-exploring probe at the starting position.

10.2.4 Set the exploring probe on a new MOS capacitor at the next position.

10.2.5 Bias the applied voltage to zero volts ($V_{app}(0) = 0$). Record the oxide leakage current and the voltage.

10.2.6 Increase the applied voltage by a step increment ($V_{app}(n) = V_{app}(n - 1) + \Delta V$). Measure the current I(n) and the voltage at the step after the hold time (T_h), and record them. Where "n" is the step number. At the first step, $V_{app}(1) = V_{app}(0) + \Delta V$.

10.2.7 If the applied voltage is equal to or large than the maximum stress voltage ($V_{app}(n) \geq V_{max}$), record the maximum stress voltage (V_{max}) as the breakdown voltage (V_{bd}) with MOS address, and proceed to Section 10.2.9. If V_{app} is less than V_{max}, proceed to next step.

10.2.8 Check to see if the current I(n) has reached the judgment current of breakdown (I_{bd}). If so, record the applied voltage (V_{app}) with each MOS address as the breakdown voltage (V_{bd}), and proceed to Section 10.2.9. If not, repeat from Section 10.2.6.

10.2.9 Check to see if there are any more MOS capacitors to be measured. If so, repeat from Section 10.2.4 until all MOS capacitors are tested.

10.2.10 Report the results.

10.2.11 The maximum stress electric field (E_{max}), increment of step field (ΔE) and applied field (E_{app}) can also be used as the measurement parameters. They can be obtained by calculation as shown in Section 10.2.

10.2.12 Figure 2 is a flow diagram outlining the procedure for this test method.

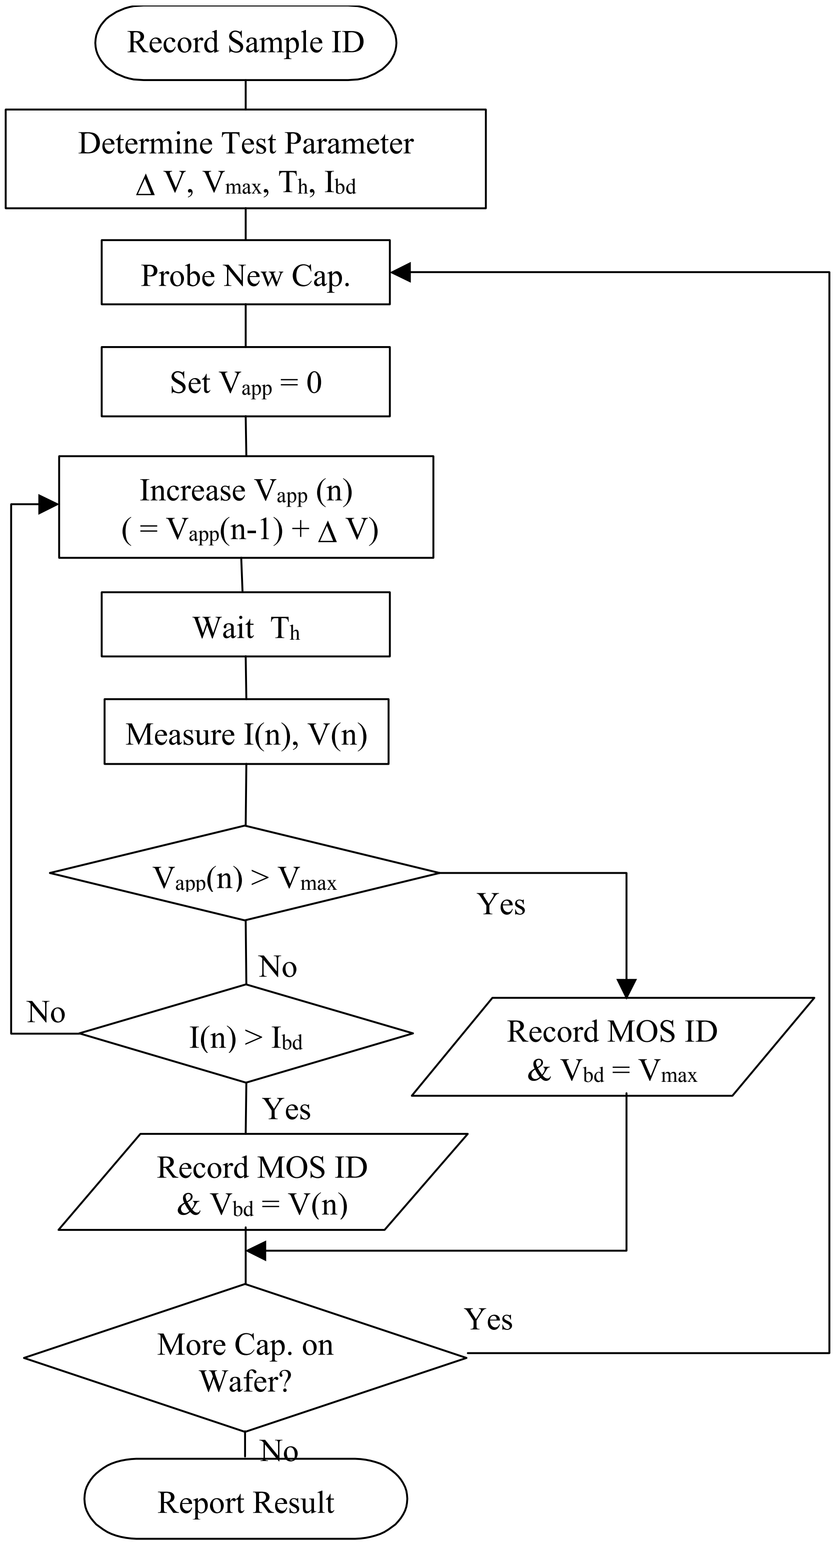

Figure 2
Flow Diagram Outline

11 Calculations

11.1 *Current and Current Density*

To calculate the oxide leakage current (I) from an oxide leakage current density (J), multiply the current density by the area of gate contact (S) as follows:

Symbolically: $I = J \times S$ (1)

Example: Given a current density (J) of 1 µA/cm^2 and a gate area (S) of 10 mm^2, the current would be 100 nA.

Similarly, compute current density (J, [A/cm^2]) from measured current (I, [A]) and area (S, [cm^2]) using.

$J = I / S$ [A/cm^2] (2)

11.2 *Voltage and Electric Field Strength*

To calculate voltage (V) from an electric field (E), multiply the electric field strength by the gate oxide thickness (T_{ox}) as follows:

Symbolically: $V = E \times T_{ox}$ (3)

Tox = gate oxide thickness, cm

Example: Given an electric field (E) of 15 MV/cm and a gate oxide thickness (Tox) of 25 nm, the voltage would be 37.5 V.

Similarly, compute electric field (E, [MV/cm]) from measured voltage (V, [V]) and gate oxide thickness (T_{ox}, [cm]) using.

$E = V / T_{ox}$ [MV/cm] (4)

11.3 *Oxide Voltage*

The applied voltage across an MOS capacitor has offset. The offset voltage due to gate-substrate work function difference [Φ_{ms}] and oxide fixed charge [Q_f]. Although it is better to consider this offset voltage, the influence of the offset voltage is small for the oxide film thickness in the range recommended in this test method and then it is not mandatory.

11.4 *Calculate of Defect Density*

The defect density calculation can be based on a Poisson relationship (see EIA/JEDEC 35) using the following equation:

$\rho_{ox} = -\ln(1 - F)/S$ (5)

ρ_{ox} = Defect density (defects/cm^2)

F = Failure fraction for each oxide breakdown mode

S = Capacitor gate area (cm^2)

Example: Given a total of 100 MOS capacitors tested with B mode failed 30 capacitors and a gate area of 10 mm^2, the defect density would be as follows:

$\rho_{ox} = -\ln(1-(30/100))/0.1 = 3.6$ defects/cm^2 (6)

11.5 *Weibull Distribution*

To convert cumulative percentages to Weibull format (sometimes referred to as "smallest extreme value probability distribution III"), use the following equation:

$\ln(-\ln(1 - F))$ (7)

When ln is the natural log operator and F is a fraction of cumulative failures. Care shall be taken so that F is never exactly 1 since this will be in an undefined situation.

12 Report

12.1 Report the following for each wafer, as appropriate for the test conditions and as agreed upon by the parties to the test.

12.2 *Test Description*

12.2.1 Date

12.2.2 Time

12.2.3 Operator

12.2.4 Measurement system ID

12.2.5 Sample lot ID

12.2.6 Wafer ID

12.2.7 Average oxide thickness

12.2.8 Gate area (cm^2)

12.2.9 Gate material

12.2.10 Oxidation parameters

12.2.11 Type of wafer (Ex: n or p)

12.2.12 Applied stress parameters

12.2.13 Test temperature

12.2.14 Process comment

12.3 Report the following for each capacitor.

12.3.1 Capacitor ID such as address

12.3.2 I–V character data

12.3.3 Breakdown voltage or Breakdown electric field

12.4 Report the following for each wafer.

12.4.1 Histogram and Weibull plot of breakdown electric field

12.4.2 Average of breakdown voltage, breakdown electric field

12.4.3 Breakdown mode yield (A-mode, B-mode and C-mode)

12.4.4 Breakdown mode map or E_{bd} map

12.4.5 Result of calculated defect density

RELATED INFORMATION 1
OUTLINE OF ROUND ROBIN

NOTE: This related information is not an official part of SEMI M51 and was derived from work by the originating task force. This related information was approved for publication by full letter ballot on April 26, 2002.

R1–1 MOS Structure

R1–1.1 *Gate Oxide Thickness*

R1–1.1.1 The gate oxide thickness of the MOS capacitors used to test in a round robin was 25 nm. In this round robin, we evaluated GOI of the MOS capacitors with the gate oxide film of 25 nm thick on the mirror-polished p–type CZ Si. In the TZDB evaluation, a negative electric field was raised step by step from 0 to 15MV/cm, and an oxide leakage current value was measured. When the oxide leakage current first exceeded the dielectric breakdown judgment value, we judged that the gate oxide film dielectrically broke down.

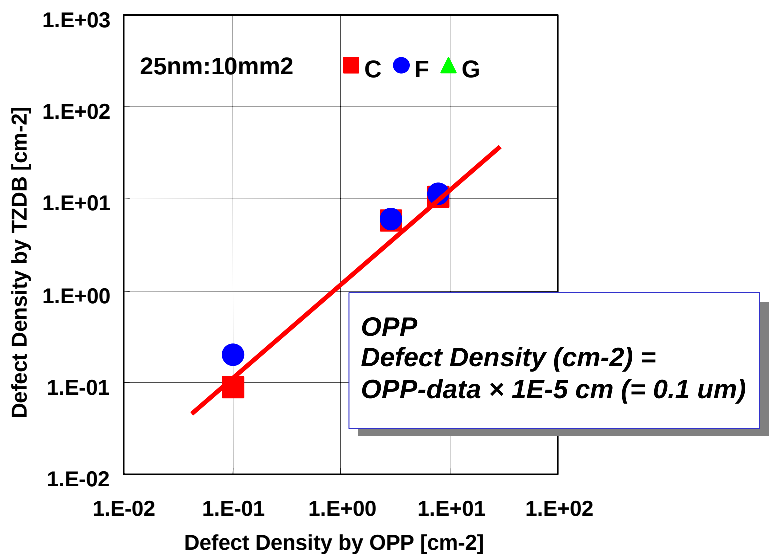

Figure R1–1
A Relationship between B-mode Defect Density in TZDB and Defect Density of OPP

R1–1.1.2 The graph above shows the relation between B-mode defect density by TZDB of 25 nm thick oxide and defect density by optical precipitate profiler (OPP). Here, based on an assumption that the dielectric breakdown defect is in conform with the Poisson distribution, the defect density by TZDB of 25 nm thick oxide, ρ, was calculated from the dielectric breakdown failure fraction of TZDB, F, as follows.

$\rho_{ox} = -\ln(1-F)/S$ (8)

Here, S is a gate electrode area of the evaluated MOS capacitors.

R1–1.1.3 The defect density was obtained by the B-mode failure fraction, F, of TZDB. On the other hand, estimation of the defect density by OPP was carried out as follows. The OPP defects were measured the wafers at the same position (ingot) of the same Si crystal as the sample wafers. The COP which appeared on the Si wafer surface was estimated from a volume defect density, n(cm^{-3}), and a diameter of the COP, L(cm) . The area density of the defects which appear at the Si surface can be estimated with n × L, assuming that the COP diameter, L, is almost uniform and the volume defect density, n, is uniformly distributed. Here, 0.1 μm as the L value[7] and the measurement results by the OPP technique as the n value were used. As a result, the OPP defect densities by which each three kinds of Si wafers, H, M, and L, was characterized became as follows.

H: $n = 7.83 \times 10^5 (cm^{-3}) \Rightarrow \rho_{ox} = 7.8 (cm^{-2})$

M: $n = 2.89 \times 10^5 (cm^{-3}) \Rightarrow \rho_{ox} = 2.9 (cm^{-2})$

L: $n \leq 1 \times 10^4 (cm^{-3}) \Rightarrow \rho_{ox} \leq 0.1 (cm^{-2})$

In the graph above, the sign of C, F, and G is measurement results for the MOS capacitors made in different three wafer vendors. The defect density by TZDB and the defect density by OPP can be seen the relation of almost 1:1 in this figure. These facts mean that the B-mode defect of the 25 nm-thick gate oxide is mainly attributed to the COP's that appear at the Si wafer surface. Moreover, these results indicate that this standard test method can gives us the evaluation of the oxide defect densities over the wide range of the COP defect density with excellent reproducibility.

R1–1.2 *Total Number and Electrode Area of Measured MOS Capacitors*

R1–1.2.1 To measure with high sensitivity of some defect density, the large number of the MOS capacitors with a large electrode area shall be measured. However, the measurement of too large area and too large number of the MOS capacitors leads to unnecessary evaluation load. Appropriate area size and a total number of the measurement MOS capacitors to evaluate the defect density at the Si wafer surface shall be selected depending on a foreseen defect density and a purpose of an evaluation. For instance, if you have a purpose to evaluate the conventional mirror polished CZ Si wafer with a defect density of 1-10/cm^2, you must measure about 100 MOS capacitors with an electrode area of 10–20 mm^2.

R1–1.2.2 When the Poisson's distribution is assumed as a defect distribution as mentioned above, the yield, Y, of the MOS capacitors with the electrode area of S and the defect density of ρ_{ox} is given by the following equation.

$Y = 1 - F = \exp(-\rho_{ox} S)$

R1–1.2.3 The failure fraction, F, is calculated using this expression. Here, the necessary MOS capacitor number, n, for the observation of one breakdown MOS capacitor is assumed to be 1/F. Thus, this n was calculated from the value of S and ρ_{ox} as shown in Table R1-1.

Table R1-1 Necessary Number for Observation of One Breakdown MOS Capacitor

1/F = Necessary number for observation of one breakdown MOS capacitor

S(mm^2)	*1*	*5*	*10*	*20*	*50*
$\rho_{ox} = 10\ cm^{-2}$	11	3	2	1	1
$\rho_{ox} = 1\ cm^{-2}$	101	21	11	6	3
$\rho_{ox} = 0.1\ cm^{-2}$	1001	201	101	51	21

R1–1.2.4 In the same way, the yield probability, Y, and necessary number, n, for observation of available MOS capacitors was calculated as indicated in Table R1-2.

Table R1-2 Necessary Number for Observation of Available MOS Capacitor

1/Y = Necessary number for observation of available MOS capacitor

S(mm^2)	*1*	*5*	*10*	*20*	*50*
$\rho_{ox} = 10\ cm^{-2}$	1	2	3	7	148
$\rho_{ox} = 1\ cm^{-2}$	1	1	1	1	2
$\rho_{ox} = 0.1\ cm^{-2}$	1	1	1	1	1

R1–1.2.5 The number of needed MOS capacitors is shown in Table R1-3 though both "1/F" and "1/Y" were done to one or more. If it wants to observe ten MOS capacitors or more respectively in an actual evaluation including reproducibility, the number of needed MOS capacitors for the measurement will be the multiplied ten and reaches the value of the Table R1-3 inside below.

Table R1-3 Necessary Number of MOS Capacitors (in the case of ρ_{ox} = 1 or 10)

S (mm²)	*1*	*5*	*10*	*20*	*50*
Confirmation of breakdown (ρ_{ox} = 1)	101	21	11	6	3
Confirmation of alive (ρ_{ox} = 10)	1	2	3	7	148
Necessary number (large one in above)	101	21	11	7	148
×10	1010	210	110	70	1480

In Table R1-3, the term of confirmation of breakdown (ρ_{ox} = 1) means the number of element necessary to confirm at least one breakdown in the case of ρ_{ox} = 1, and the term of confirmation of alive (ρ_{ox} = 10) means the number of element necessary to confirm at least one alive in the case of ρ_{ox} = 10.

R1–1.2.6 When the Si wafer with surface defect density of 10 /cm^2 is measured, if the MOS capacitors with an electrode area of 50 mm^2 are used, it breaks down surely. Therefore, we understand it is unsuitable in the comparative evaluation of the defect distribution as for this condition.

R1–1.2.7 If we want to confirm that 10 MOS capacitors are "alive" or "dead", it is necessary to measure 70 MOS capacitors of 20 mm^2, or 110 MOS capacitors with an electrode area of 10 mm^2, or 210 MOS capacitors of 5 mm^2.

R1–1.2.8 When the defect of sample wafer is 0.1 /cm^2, we can confirm broken 10 MOS capacitors of 50 mm^2 by measurement of only 210 MOS capacitors. For MOS capacitors of 1 mm^2, it will be necessary to measure about 10000, and this is not realistic.

R1–1.3 *Recommended Measurement Condition*

R1–1.3.1 An electric field step, E_{step}, and a hold time, T_{hold}, used in this round robin were shown in Figure R1-2.

TZDB(Step Voltage)

a) Group I: B,D,E b) Group II: A,F

T_{hold}(ms)	E_{step}(MV/cm) 0.1	0.25	0.5	1.0
100	I	I	-	-
200	II	I*, II	II	II
800	-	I	I	-

(* E measured T_{hold}=400ms)

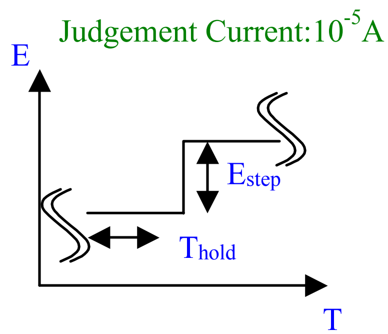

Figure R1-2
Applied Gate Electric Field Stress Condition in TZDB and Measurement Group Division.

R1–1.3.2 In the measurement of TZDB, the voltage is stepwise increased. Then, the electric current is measured after a constant hold time. This hold time is usually installed as a time for measurement stabilization. It is possible that the measurement result receives the influence of instability when the hold time is shorter than 100 ms.

R1–1.3.3 On the other hand, because too long hold time, that is, 800 ms or more, leads to a long total measurement time, the influence of TDDB becomes conspicuous in the high electrical field region, and it is a possible that the breakdown failure fraction of the MOS capacitors increases.

R1–1.3.4 In Figure R1-2, the B-mode failure fractions are shown as a function of the hold time of the applied electric field stress with a step height of 0.25 MV/cm. The hold time from100 ms to 800 ms did not especially have any influence in the measurement results of this round robin. Then, we proposed 200 ms as a practicable recommended hold time.

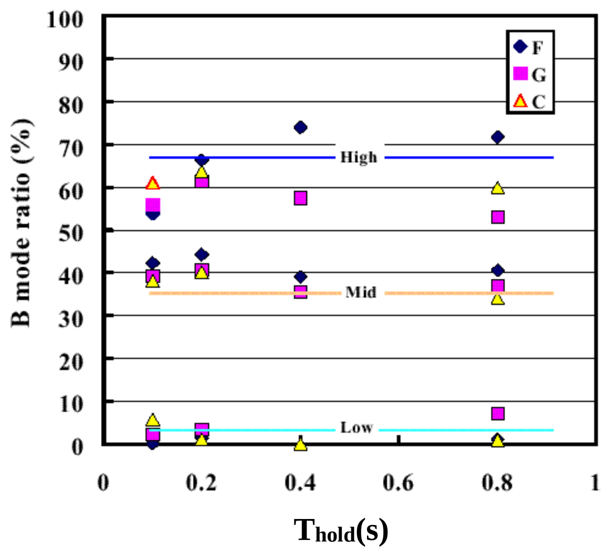

Figure R1-3
B-Mode Failure Fraction vs. Hold Time of Applied Electric Field Stress with a Step Height of 0.25 MV/cm in TZDB

R1–1.3.5 In this TZDB measurement, the applied electric field was stepwise increased directly after the current measurement. Too low step height of the applied electric field, ΔE, that is, 0.1 MV/cm or less, leads to unnecessary long measurement time, and the influence of TDDB becomes conspicuous in the high electrical field region.

R1–1.3.6 On the other hand, too high step of the applied electric field stress, for example, 1.0 MV/cm or more, leads to broadening of the dielectric breakdown electric field. That is, the reliability of the measurement result is decreased.

R1–1.3.7 In this round robin as shown in Figure R1-4, the B-mode failure fraction did not depend on the step height of the applied electric field stress with a hold time of 200 ms. The electric field step height of 0.1–0.5 MV/cm did not especially have any problem in the measurement results. In addition, considering the above practical factors, we recommend the step height range of 0.1–0.5 MV/cm, and especially, 0.25 MV/cm.

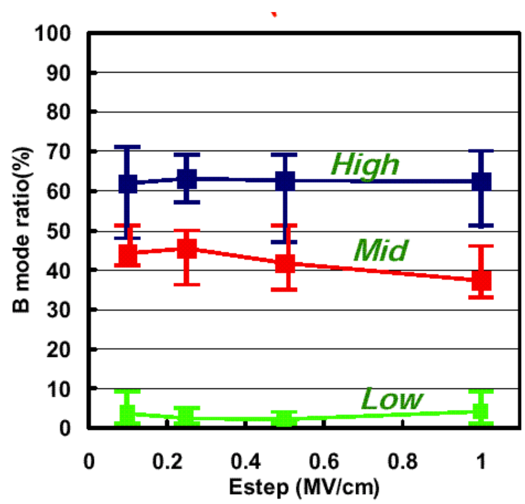

Figure R1-4
B-Mode Failure Fraction vs. Step Height of the Electric Field Stress with a Hold Time of 200 ms in TZDB

SEMI INTERNATIONAL STANDARDS

MICROLITHOGRAPHY

Semiconductor Equipment and Materials International

SEMI P1-1101
SPECIFICATION FOR HARD SURFACE PHOTOMASK SUBSTRATES

This specification was technically approved by the Global Micropatterning Committee and is the direct responsibility of the North American Micropatterning Committee. Current edition approved by the Japanese Regional Standards Committee on August 3, 2001. Initially available at www.semi.org September 2001; to be published November 2001. Originally published in 1981; previously published February 1999.

1 Purpose

1.1 This specification covers the general requirements of the glass substrate for hard surface photomasks.

2 Scope

2.1 This document covers square photomasks up to 7 inches in length. 230 mm substrates are excluded from this standard and can be found in SEMI P33.

2.2 This document also gives specifications for the following materials:

- High Thermal Expansion (HTE),
- Medium Thermal Expansion (MTE),
- Low Thermal Expansion (LTE),
- Ultra Low Thermal Expansion (ULTE)
- Durable Fused Silica (DFS) glass for 193 nm wavelength
- Modified Fused Silica (MFS) glass for 157 nm wavelength.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety health practices and determine the applicability or regulatory limitations prior to use.

3 Referenced Standards

3.1 *SEMI Standards*

SEMI P33 — Provisional Specification for Developmental 230 mm Square Hard Surface Photomask Substrates

3.2 *ASTM Standards*[1]

ASTM E 228 — Test for Linear Thermal Expansion of Rigid Solids with a Vitreous Silical Dilatometer

3.3 *ANSI/ASQC Standards*[2]

ANSI/ASQC Z1.4 — Sampling Procedures and Tables for Inspection by Attributes

3.4 *ISO Standard*[3]

ISO 14644-1 — Cleanrooms and Associated Controlled Environments Part 1: Classification of Air Cleanliness

4 Terminology

4.1 Selected terms relating to photomasking are given for information only in "Terms and Definitions Relating to the Microlithography Industry" found at the end of SEMI P33 "RELATED INFORMATION". Definitions may be found in what was ASTM F 127.

5 Ordering Information

5.1 Purchase orders for hard surface photomask substrates furnished to this specification shall include the following:

5.1.1 Nominal edge length, nominal thickness dimension, and edge criteria (see Section 6);

5.1.2 Material (see Section 7);

5.1.3 Flatness quality area and flatness (Total Indicated Reading, T.I.R.) see Section 8);

5.1.4 Visual quality area and defect limits (see Section 9); and

5.1.5 Lot acceptance criteria (see Section 10).

6 Dimensions and Permissible Variations

6.1 The square substrates shall conform to the dimensional tolerances appropriate to the nominal edge length and thickness as listed in Table 1. Dimensions are illustrated in Figure 1 and a fixture for measuring the diagonal dimensions is shown in Figure 2.

6.2 Substrates shall have chamfered or rounded edges. The edges shall conform to the dimensional tolerances

2 American Society for Quality Control, 611 East Wisconsin Avenue, Milwaukee, WI 53202, USA

3 International Organization for Standardization, ISO Central Secretariat, 1, rue de Varembé, Case postale 56, CH-1211 Geneva 20, Switzerland. Telephone: 41.22.749.01.11; Fax: 41.22.733.34.30 Website: www.iso.ch

appropriate to the nominal thickness listed in Table 2. Dimensions are illustrated in Figures 3 and 4.

7 Material Specifications

7.1 Substrate materials shall be specified as high thermal expansion (HTE), medium thermal expansion (MTE), low thermal expansion (LTE), ultra low thermal expansion (ULTE), durable fused silica (DFS), or modified fused silica (MFS). Examples of HTE materials are white crown and soda lime glasses, of MTE materials are borosilicate and aluminosilicate glasses, of LTE materials are aluminosiliate glasses, and of ULTE, DFS, and MFS materials are quartz (silica).

7.2 Substrate materials shall conform to thermal expansion and optical transmittance characteristics specified in Table 3.

7.2.1 DFS shall maintain the transmittance given in Table 3 within 0.3% change at least accumulated dosage of 100 kJ/cm^2 of 193 nm wavelength irradiation.

7.3 Selected physical properties of HTE, MTE, LTE, ULTE, DFS, and MFS materials are provided for information only in Appendix 1.

8 Flatness Specifications

8.1 Substrates shall be supplied with one side having a flatness (TIR) of 0.25, 0.5, 1, 2, 5, 10, or 20 µm over a circular or square quality flatness area as defined in Figures 5 and 6.

9 Visual Criteria

9.1 A visual quality area, which may or may not correspond with the flatness area, shall be agreed upon between the user and supplier.

9.2 Each plate shall not have more defects than listed in Table 4. This table includes limits for the following types of defects:

9.2.1 Internal defects in the quality area,

9.2.2 Frontside surface defects,

9.2.3 Backside surface defects, and

9.2.4 Defects outside the quality area.

9.3 Glass substrates shall be identified with notches on the backside corner as shown in Figure 7. Soda lime and white crown (HTE) glasses are marked with one corner notch (Figure 7a). Borosilica and Aluminosilicate (MTE) glasses are marked with three corner notches (Figure 7b). Aluminosilica (LTE) glass is marked with two adjacent corner notches (Figure 7c). Quartz (ULTE) is marked with two diagonal corner notches (Figure 7d). Quartz (DFS) is marked with one corner notch (Figure 7e), that is the same as specified for HTE. Quartz (MFS) is marked with one non-isosceles triangle corner notch (Figure 7f). Dimensions of notches shall be as specified in Figure 8. If desired, and so specified in the contract or order, notches are positioned to identify the squareness origin corner.

10 Sampling

10.1 Unless otherwise specified, appropriate sample sizes shall be selected from each lot in accordance with ANSI/ASQC Z1.4. Each quality characteristic shall be assigned an acceptable quality level (AQL) in accordance with ANSI/ASQC Z1.4 definitions for critical, major, and minor classifications. If desired, and so specified in the contract or order, each of these classifications may alternatively be assigned cumulative AQL values. Inspection levels shall be agreed upon between user and supplier.

11 Test Methods

11.1 *Thermal Expansion* — Determine in accordance with ASTM E 228.

11.2 Transmission (to be agreed upon between user and supplier).

11.3 Irradiation durability (to be agreed upon between user and supplier).

11.4 Flatness (to be agreed up between user and supplier).

11.5 Visual (to be agreed upon between user and supplier).

12 Handling

12.1 Substrates are to be handled on the edges only. Substrates are to be handled with gloves approved for cleanroom use.

13 Certification

13.1 Upon request of the purchaser in the contract or order, a manufacturer's or supplier's certification that the material was manufactured and tested in accordance with this specification, together with a report of the test results, shall be furnished at the time of shipment.

14 Packing and Marking

14.1 Substrates shall be packed in a class 100 environment as defined by ISO 14644-1. Containers shall be designed to prevent glass-to-glass contact, and to protect the substrates from contamination in handling and transit. Substrates shall be shipped with the acceptable flatness side toward the front of the box. This orientation shall be indicated on each container. Packaging shall comply with the applicable internal, national, state, and local laws and regulations required for shipping.

14.2 Containers shall be labeled “Warning: Open and Handle Under Cleanroom Conditions Only”: as well as identified by user purchase order number (if applicable), drawing number (if applicable), quantity, supplier lot number, and material identification.

A1-1 Hard Surface Photomask Glass Properties

GLASS PROPERTIES

Property	
HIGH THERMAL EXPANSION (HTE)	
Modulus of Elasticity	$7.0–7.3 \times 10^3$ Kg/mm^2
Poisson's Ratio	0.22–0.23
Specific Gravity	2.50–2.56 g/cm^3
Index of Refraction	1.52
MEDIUM THERMAL EXPANSION (MTE)	
Modulus of Elasticity	$7.1–9.4 \times 10^3$ Kg/mm^2
Poisson's Ratio	0.18–0.26
Specific Gravity	2.36–2.87 g/cm^3
Index of Refraction	1.49–1.57
LOW THERMAL EXPANSION (LTE)	
Modulus of Elasticity	$7.5–8.7 \times 10^3$ Kg/mm^2
Poisson's Ratio	0.16–0.24
Specific Gravity	2.52–2.58 g/cm^3
Index of Refraction	1.53–1.56
ULTRA LOW THERMAL EXPANSION (ULTE)	
Modulus of Elasticity	$6.7–7.4 \times 10^3$ Kg/mm^2
Poisson's Ratio	0.16–0.19
Specific Gravity	2.18–2.20 g/cm^3
Index of Refraction	1.46
DURABLE FUSED SILICA (DFS)	
Modulus of Elasticity	$6.7–7.4 \times 10^3$ Kg/mm^2
Poisson's Ratio	0.16–0.19
Specific Gravity	2.18–2.20 g/cm^3
Index of Refraction	1.46
MODIFIED FUSED SILICA (MFS)	
Modulus of Elasticity	$6.7–7.4 \times 10^3$ Kg/mm^2
Poisson's Ratio	0.16–0.19
Specific Gravity	See NOTE 1.
Index of Refraction	See NOTE 1.

NOTE 1: Specific Gravity and Index of Refraction of MFS shall be agreed upon between user and supplier.
NOTE 2: Index of Refraction on this table is the value at 587 nm wavelength.

NOTICE: SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature, respecting any materials or equipment mentioned herein. These standards are subject to change without notice.

By publication of this standard, Semiconductor Equipment and Materials International (SEMI) takes no position respecting the validity of any patent rights or copyrights asserted in connection with any items mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights are entirely their own responsibility.

SEMI P2-0298
SPECIFICATION FOR CHROME THIN FILMS FOR HARD SURFACE PHOTOMASKS

1 Purpose

This specification covers the general requirements of the chrome thin film for hard surface photomasks.

2 Referenced Documents

2.1 *SEMI Specification*

SEMI P1 — Specification for Hard Surface Photomask Substrates

2.2 *ASTM Standard*[1]

E 122 — Choice of Sample Size to Estimate the Average Quality of a Lot or Process

2.3 *Federal Standard*[2]

209D — Clean Room and Work Station Requirements, Controlled Environment

2.4 *Military Specification*[3]

MIL-STD-105 — Sampling Procedure and Tables for Inspection by Attributes

3 Terminology

3.1 *defects, photomask* — Any flaw or imperfection in the opaque coating or functional pattern of a photomask that will reproduce itself in a photoresist film to such degree that it is pernicious to the proper functioning of the microelectric device being fabricated.

3.2 *fingerprint* — For the purposes of this practice, residual surface contamination deposited during handling.

3.3 *pinhole* — A small opening extending through a cover as a photoresist coating or an oxide layer.

4 Ordering Information

4.1 Purchase orders for hard surface photomasking substrates furnished to this specification shall include the following:

Optical Density	to be agreed upon by the user and supplier
Reflectivity	High reflective — Above 40% Medium Reflective — 2– 40% Low Reflective — Below 25%
Material	to be agreed upon by the user and supplier
Etchability	to be agreed upon by the user and supplier
Defects	to be agreed upon by the user and supplier
Lot Size	to be agreed upon by the user and supplier

5 Material Specifications

The material specifications are to be agreed upon by the user and supplier.

6 Visual Criteria

6.1 *Visual Quality Area*

6.1.1 *Circular Visual Quality Area* — (See SEMI P1, Figure 6, for available flatness limits of hard surface photomask substrates.)

6.1.2 *Square Visual Quality Area* — (See SEMI P1, Figure 7, for available flatness limits of hard surface photomask substrates.)

7 Defects

Definitons of defects and the allowable number of each type are listed in Table 1. The number of defects is indicated by plate size, chrome grades, and defect size.

8 Sampling

Unless otherwise specified, Recommended Practice ASTM E 122 shall be used. When so specified, appropriate sample sizes shall be selected from each lot in accordance with MIL-STD-105. Each quality characteristic shall be assigned an acceptable quality level (AQL) and lot total percent defective (LTPD) value in accordance with MIL-STD-105 definitions for critical. Major and minor classifications may alternatively be assigned cumulative AQL and LTPD values. Inspection levels shall be agreed upon between the user and supplier.

9 Handling

Substrates are to be handled on the edges only.

10 Certification

Upon request of the purchaser in the contract or order, a manufacturer's or supplier's certification that the

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohoken, PA 19428-2959

2 General Services Administrator, 4th and D Streets, SW, Room 6039, Washington, DC 20407

3 Military Standards, Naval Publication and Forms Center, 5801 Tabor Avenue, Philadelphia, PA 19120

material was manufactured and tested shall be in accordance with this specification.

11 Packing and Marking

11.1 Substrates shall be packed in a Class 100 environment. Containers shall be designed to prevent glass-to-glass contact and to protect the substrates from contamination in handling and transit. Substrates shall be shipped with the coated side facing toward the same end of the box. This orientation shall be indicated on each container. Packaging shall comply with the applicable international, national, state laws, and local regulations required for shipping.

11.2 Containers shall be labeled, "Warning: Open and Handle Under Clean Room Conditions Only." Each shipment shall be identified by user purchase order number, drawing number (if applicable), quantity, supplier lot number, and material identification.

SEMI P3-0298
SPECIFICATION FOR PHOTORESIST/E-BEAM RESIST FOR HARD SURFACE PHOTOPLATES

1 Purpose

1.1 This specification covers the general requirements on the photoresist and e-beam resist coating for hard surface photoplates. See SEMI P1 and SEMI P2 for requirements on physical characteristics of the photoplate substrate and the chrome coating on it.

2 Referenced Documents

2.1 *SEMI Specifications*

SEMI P1 — Specification for Hard Surface Photomask Substrates

SEMI P2 — Specification for Chrome Thin Films for Hard Surface Photomasks

2.2 *ASTM Standard*[1]

ASTM E 122 — Recommended Practice for Choice of Sample Size to Estimate the Average Quality of a Lot or Process

2.3 *Federal Standard*[2]

209D — Clean Room and Work Station Requirements, Controlled Environments

2.4 *Military Specification*[3]

MIL-STD-105 — Sampling Procedure and Tables for Inspection and Attributes

3 Terminology

3.1 *comets* — buildup of resist in the form of a comet, generated by a defect.

3.2 *defect, photomask* — any flaw or imperfection in the opaque coating or functional pattern of a photomask that will reproduce itself in a photoresist film to such a degree that it is pernicious to the proper functioning of the microelectric device being fabricated.

3.3 *fingerprint* — for the purposes of this practice, residual surface contamination deposited during handling.

3.4 *photoresist lifting* — the loss of adhesion of a photoresist coating to its substrate.

3.5 *pinhole* — a small opening extending through a cover as a photoresist coating or an oxide layer.

3.6 *residue* — any undesirable material remaining on a substrate after any process step.

3.7 *resist rings* — buildup of resist in round, multicolored rings, generated by particles or bubble bursts.

3.8 *stress marks* — radial, colored, thin lines starting in the center of the plate and extending out.

4 Ordering Information

4.1 Purchase orders for resist-coating for hard surface photoplate substrates furnished to this specification shall include the following in addition to the information called for in SEMI P1 and SEMI P2:

4.1.1 Resist Material

4.1.2 Resist Thickness and Tolerance in the Quality Area

4.1.3 Resist Uniformity across the Quality Area

4.1.4 Resist Consistency — from Plate to Plate

4.1.5 Resist Baking Time and Temperature

5 Visual Criteria

5.1 *Visual Quality Area*

5.1.1 *Circular Visual Quality Area* — (See SEMI P1, Figure 6, for Available Flatness Limits of Hard Surface Photomask Substrates.)

5.1.2 *Square Visual Quality Area* — (See SEMI P1, Figure 7, for Available Flatness Limits of Hard Surface Photomask Substrates.)

6 Defects

6.1 Definitions of defects and the allowable number of each type are noted in Table 1. The number of defects is indicated by plate size, chrome grades, and defect size.

7 Sampling

7.1 Unless otherwise specified, Recommended Practice ASTM E 122 shall be used. When so specified, appropriate sample sizes shall be selected from each lot in accordance with MIL-STD-105. Each quality

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohoken, PA 19428-2959

2 General Services Administrator, 4th and D Streets, SW, Room 6039, Washington, D.C. 20407

3 Military Standards, Naval Publication and Form Center, 5801 Tabor Avenue, Philadelphia, PA 19120

characteristic shall be assigned an acceptable quality level (AQL) and lot total percent defective (LTPD) value in accordance with MIL-STD-105. Definitions for critical, major, and minor classifications may alternatively be assigned cumulative AQL and LTPD values. Inspection levels shall be agreed upon between the user and supplier.

8 Handling

8.1 Resist-coated substrates are to be handled on the edges only with approved finger cots or gloves under clean room conditions.

9 Certification

9.1 Upon request of the purchaser in the contract or order, a manufacturer's or supplier's certification that the material was manufactured and tested in accordance with this specification shall be provided.

10 Packaging and Marking

10.1 Resist-coated substrates shall be packed in a Class 100 environment as defined in Federal Standard 209D. Containers shall be designed to prevent movement and glass-to-glass contact and to protect the substrates from contamination in handling and transit. Orientation of the coated side shall be indicated on each container. Packaging shall comply with the applicable international, national, state, and local laws and regulations required for shipping.

10.2 Each shipment shall be identified by user purchase order number, drawing number (if applicable), quantity, supplier lot number, material identification, bake time and temperature, resist type, resist lot number, and date of applying resist.

10.2.1 *Photoresist* — Containers shall be labeled, "Warning: Open and Handle Under Safe Yellow Light in Clean Room Conditions Only."

10.2.2 *E-Beam Resist* — Containers shall be labeled, "Warning: Open and Handle Under Clean Room Conditions Only. DO NOT X-RAY."

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI P4-92 (Reapproved 0299)
SPECIFICATION FOR ROUND QUARTZ PHOTOMASK SUBSTRATES

This specification was technically reapproved by the Mask & Mask Equipment Committee and is the direct responsibility of the North American Microlithography Committee. Current edition approved by the North American Regional Standards Committee in October 1998. Initially available at www.semi.org February 1999; to be published February 1999. Originally published in 1983; previously published in 1996.

Editorial changes were made to the following: Sections: 2.2, 6.2, and 13.1, Tables 3, 4 and 5, and Figure 5.

General Requirements

1. Preface

This specification covers the general requirements of the quartz round substrate for hard surface photomasks.

2. Applicable Documents

2.1 *ASTM Standards*[1]

ASTM E 122 — Recommended Practice for Choice of Sample Size to Estimate the Average Quality of a Lot or Process

ASTM E 228 — Standard Test Method for Linear Thermal Expansion of Rigid Solids with a Vatreous Silical Dilatometer

2.2 *ISO Standard*[2]

ISO 14644-1 — Cleanrooms and Associated Controlled Environments Part 1: Classification of Air Cleanliness

2.3 *Military Specifications*[3]

MIL-STD-105 — Sampling Procedure and Tables for Inspection and Attributes

3. Terminology

None.

4. Ordering Information

Purchase orders for hard surface photomask substrates furnished to this specification shall include the following:

Dimensions	(See Section 5)
Material	(See Section 6)
Flatness Criteria	(See Section 7)
Visual Criteria	(See Section 8)
Lot Acceptance	(See Section 9)

5. Dimensions and Permissible Variations

The material shall conform to the dimensions and dimensional tolerances as specified in Tables 1 and 5, Dimensions for Round Quartz Photomask Substrates.

6. Material Specifications (ULTE glass only)

6.1 *Thermal Characteristics 0–300°C*

6.1.1 *100% Quartz Material* — Coefficient of expansion 5.5×10^{-7}/°C.

6.1.2 *Less Pure Quartz* — Coefficient of expansion less than 7.5×10^{-7}/°C.

6.2 *Transmission Characteristics*[4]

Wave Lengths	*Minimum % @ 1.5 mm Thickness*
200 nm	To be agreed upon between user and supplier.
230 nm	To be agreed upon between user and supplier.
254 nm	To be agreed upon between user and supplier.
365 nm	To be agreed upon between user and supplier.
405 nm	To be agreed upon between user and supplier.

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohoken, PA 19428-2959

2 ISO Central Secretariat, 1, rue de Varembé, C.P. 56, CH-1211 Genève 20, Switzerland

3 Military Standards, Naval Publications and Form Center, 5801 Tabor Avenue, Philadelphia, PA 19120

4 After correction for surface reflection

6.3 *Physical Properties* — Information on the following properties is provided for information only. (See Appendix 1.)

6.3.1 Poisson's Ratio

6.3.2 Density

6.3.3 Young's Modulus

6.3.4 Modulus of Elasticity

6.3.5 Index of Refraction

6.3.6 Volume Restivity

7. Flatness Area (for one side only)

7.1 *Flatness Quality Area*

7.1.1 *Circular Flatness Quality Area* — (See Tables 2 and 5.)

8. Visual Criteria (one side only)

8.1 *Quality Area* — (See Tables 2 and 5.)

Plate Diameter	*Quality Area (Diameter)*
125 mm	113 mm
150 mm	138 mm

8.2 *Defect Limits* — Defects and allowable number of each type are listed in Table 4.

8.2.1 *Terminology for SEMI P4* — Unless otherwise noted, the SEMI Terms and Definitions Relating to the Microlithography Industry shall be used.

8.2.2 *Minimal Conditions or Dimensions* — Minimal conditions or dimensions for defects are listed in Table 4 and shall be used for determining substrate acceptability unless other minimal limiters are agreed upon by the interested parties.

8.2.3 *Photomask Substrate Edge Criteria* — (See Table 3.)

8.3 *Identification* — To be agreed upon between the user and supplier.

9. Sampling

Unless otherwise specified, ASTM E 122 shall be used. When so specified, appropriate samples sizes shall be selected from each lot in accordance with MIL-STD-105D. Each quality characteristic shall be assigned an acceptable quality level (AQL) and lot total percent defective (LTPD) value in accordance with MIL-STD-105D. Definitions for critical, major and minor classifications may alternatively be assigned cumulative AQL and LTPD values. Inspection levels shall be agreed upon between the user and supplier.

10. Test Methods

10.1 *Thermal Expansion* — Determine in accordance with ASTM E 228.

10.2 *Transmission* — (To be agreed upon between the user and supplier).

10.3 *Flatness* — (To be agreed upon between the user and supplier).

10.4 *Visual* — (To be agreed upon between the user and supplier.)

10.5 *Roundness* — 2 readings at 90° with appropriate tool such as Vernier Caliper or equivalent. Roundness values not specified at this time.

11. Handling

Substrates are to be handled on the edges only. Substrates are to be handled only with clean room approved gloves.

12. Certification

Upon request of the purchaser in the contract or order, a manufacturer's or supplier's certification that the material was manufactured and tested in accordance with this specification together with a report of the test results shall be furnished at the time of shipment.

13. Packing and Marking

13.1 Substrates shall be packed in a class 100 environment as defined by ISO 14644-1. Containers shall be designed to prevent glass-to-glass contact and to protect the substrates from contamination in handling and transit. Substrates shall be shipped with the acceptable flatness side toward the front of the box. This orientation shall be indicated on each container. Packaging shall comply with the applicable international, national, state, and local laws and regulations required for shipping.

13.2 Containers shall be labeled "Warning: Open and Handle Under Clean Room Conditions Only." Each shipment shall be identified by user purchase order number, drawing number (if applicable), quantity, vendor lot number and material identification.

APPENDIX 1

NOTE: This appendix was approved as an official part of SEMI P4 by full letter ballot procedure.

Hard Surface Photomask Glass Properties — Quartz Properties

Property

Ultra Low Thermal Expansion Ulte	
Modulus of Elasticity	$6.7\text{-}7.4 \times 10^3$ Kg/mm^2
Poisson's Ratio	0.18-0.19$^{(1)}$
Specific Gravity	2.18-2.20 g/cm^3
Index of Refraction	1.46

NOTE: These properties are not absolute requirements. For more specific information, contact your individual supplier.

SEMI P5-94
SPECIFICATION FOR PELLICLES

1 Preface

This specification covers requirements for pellicles used on photomasks or reticles in photolithographic exposure systems. This specification covers pellicles for use in either polychromatic or monochromatic exposure systems.

2 Applicable Documents

2.1 *ASTM Standard*[1]

2.2 *Federal Standard*[2]

209 D — Clean Room and Work Station Requirements, Controlled Environments

3 Definitions

3.1 Additional terms are listed for information only in the glossary, SEMI Terms and Definitions Relating to the Microlithography Industry.

3.2 *Selected Definitions*

3.2.1 *Pellicle* — A thin, optically transparent film, typically of nitrocellulose (cellulose nitrate), attached to and supported by a frame, and attached to a photomask (or reticle). Its purpose is to seal out contaminants and reduce printed defects caused by contamination in the image plane of an optical exposure system with a minimum decrease in the quality of optical transmission.

3.2.2 *Film Adhesive* — Adhesive between frame and film.

3.2.3 *Frame Adhesive* — Adhesive between frame and photomask.

3.2.4 *Mechanical Strength* — The physical condition a pellicle must meet to withstand a specified force from a blow-off gun without suffering any damage to the film due to stretching or breakage.

3.2.5 *Film Defects* — Inconsistencies in the integrity and planarity of the film, including particles, pinholes, scratches, dirt, and a minute quantity of solid.

3.2.5.1 *Particle* — Materials which can be distinguished from the film whether on the film surface or embedded in the film.

3.2.5.2 *Dirt* — Fingerprint; mark left behind after operator handling; stain from liquid.

3.2.5.3 *Pinhole* — A small opening completely through a polymer film.

3.2.5.4 *Scratch* — Long, narrow, shallow groove or cut below the established plane of the surface.

3.2.6 *Adhesive Stringer* — Any detectable protrusion from the edge of the adhesive.

4 Ordering Information

4.1 Purchase orders of pellicles furnished to this specification shall include the following:

4.1.1 Shape, Size, and Standoff of pellicles.

4.1.2 Film Characteristics

4.1.2.1 Type (i.e., AR–coated, non-AR–coated)

4.1.2.2 Exposure Range or Wavelength

4.1.2.3 Optical Transmission Rate

4.1.2.4 Thickness

4.1.2.5 Mechanical Strength

4.1.3 Defect Limits

4.2 In addition, the following items may also be specified:

4.2.1 Frame

4.2.1.1 Shape, Size, and Height

4.2.1.2 Materials or Type

4.2.2 Frame Adhesive

4.2.2.1 Materials or Type

4.2.2.2 Thickness and Width

5 Requirements

5.1 *Film Adhesive*

5.2 *Frame Adhesive*

5.3 *Frame*

5.4 *Light Resistance*

5.5 Other Characteristics — Other characteristics of pellicles are to be determined between the supplier and the user. The transmission of light for mask alignment is such a characteristic.

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohoken, PA 19428-2959

2 General Service Administrator, 4th & D Streets, SW, Room 6039, Washington, DC 20407

6 Measurement Methods

6.1 Measurement methods are to be determined between the user and supplier. General and example methods are as follows:

Optical Transmission: by spectrophotometer

Optical Film Thickness: by spectrophotometer

Thickness Uniformity: by monochromatic (e.g., green) light

Width of Film Adhesive: Visual check by minimum defect sample

Defects: Visual check by maximum sample or particle detector

7 Sampling

7.1 Inspection levels shall be agreed upon between the user and supplier.

8 Handling

8.1 Pellicles are to be handled by the frame only.

9 Certification

9.1 Certification is to be determined between the user and supplier.

SEMI P5.1-94
STANDARD FOR PELLICLES FOR USE IN POLYCHROMATIC EXPOSURE SYSTEMS

1 Scope

This specification includes all characteristics of pellicles for use in polychromatic exposure systems.

2 Shape, Size, and Standoff of Pellicle

2.1 *Shape* — This is determined by agreement between the user and supplier.

2.2 *Size* — This is determined by agreement between the user and supplier, but expression of tolerance is as follows:

Outer diameter tolerance: +0, -x

Inner diameter tolerance: +x, -0

2.3 *Standoff* — This is determined by agreement between the user and supplier. But expression of tolerance is as follows:

Tolerance: +0, -x

3 Film Characteristics

3.1 *Polymer Films*

3.1.1 *Type* — AR-coated or non AR-coated.

3.1.2 *Exposure Range* — 360 nm–440 nm.

3.1.3 *Optical Transmission Rate* — There are the following two types depending on optical transmission rate at an incident angle of 90° from surface of pellicle.

Type	*Average*	*Minimum*
AR-Coated	≥98%	96%
Non-AR-Coated	≥91%	82%

3.1.4 *Thickness* — This is determined by agreement between the user and supplier.

3.1.4.1 *Thickness Conformity* — ± 0.2 µm maximum.

3.1.4.2 *Thickness Uniformity*

3.1.4.3 *Film Thickness*

3.1.5 *Mechanical Strength* — The requirements for air blow are determined within ranges shown below.

The air blow gun should be used;

Air pressure: ≤ 2.1 kgf/cm^2 (at input of the air blow gun)

Nozzle diameter of the air blow gun: ≤ 2 mm

Distance between the nozzle tip and the film: ≥ 25 mm

4 Defect Limits

4.1 Maximum defect limits based on the pellicle standoff and the numerical aperture of the given type of exposure system are given in Table 1. Any departure from these defect limits shall be agreed to between supplier and the user. Maximum defect limits are given in Table 1.

5 Requirements

5.1 *Film Adhesive* — Film must be sealed on the entire top of the frame with a minimum of 50% of the frame width at any location.

5.2 *Frame Adhesive* — Frame adhesive must be continuous and allow no gaps between pellicle frame and adhesive and between adhesive and photomask after attachment. No part of the frame adhesive may extend beyond the frame wall, and its edges must be free of visually detectable stringers (and particles). Adhesive should form a complete seal between the frame and the mask over a minimum of 60% of the width of the frame.

5.3 *Frame* — Pellicle frame must have no visually detectable machining burrs, discontinuities in anodization, or particles.

5.4 *Light Resistance* — This is expressed by total exposure energy value (mj/cm^2 or j/cm^2) on pellicle film until dropping 1% of optical transmission (rate) of one of the peak wavelengths between 360 nm–440 nm. Also the test conditions (special characteristics of exposure wavelength, exposure energy between 360 nm –440 nm, exposure conditions, and others) must be clear.

Table 1 Maximum Defect Limits

Characteristics	*Max. No. Allowable*	*Size counted for Max. No. Allowable*
Non-removable		≥45µm
Particles	None	
Pinholes	None	>limit of detection
Scratches	None	Width ≥45µm
Dirt	None	>limit of detection

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI

SEMI P5.2-94
STANDARD FOR PELLICLES FOR USE IN "G", "H", and "I" LINE EXPOSURE SYSTEMS

1 Scope

This specification includes the characteristics of pellicles for use in "g" (436 nm), "h" (405 nm), and "i" (365 nm) line exposure systems.

2 Shape, Size, and Standoff of Pellicle

2.1 *Shape* — This is determined by agreement between the user and supplier.

2.2 *Size* — This is determined by agreement between the user and supplier, but expression of tolerance is as follows:

Outer diameter tolerance: +0, -x

Inner diameter tolerance: +x, -0

2.3 *Standoff* — 6.3 mm and 4.0 mm should be standard.
Tolerance: +0, -x

3 Film Characteristics

3.1 Polymer Films

3.1.1 *Type* —AR-coated or non AR-coated.

3.1.2 *Exposure Wavelength* — "g", "h", and/or "i" lines.

3.1.3 *Optical Transmission Rate* — There are the following two types depending on optical transmission rate at incident angle of 90° from surface of pellicle at the specified wavelength(s).

Type	*Minimum*
AR Coated	99 percent
Non AR Coated	98 percent

3.1.4 *Thickness* — This is determined by agreement between the user and supplier.

3.1.4.1 *Thickness Conformity* — ± 0.2 µm maximum.

3.1.4.2 *Thickness Uniformity*

3.1.4.3 *Film Thickness*

3.1.5 *Mechanical Strength* — The requirements for air blow are determined within ranges shown below:

The air blow gun should be used.

Air pressure: ≤ 2.1 kgf/cm^2 (at input of the air blow gun).

Nozzle diameter of the air blow gun: ≤ 2 mm.

Distance between the nozzle tip and the film: ≥ 25 mm.

4 Defect Limits

4.1 Maximum defect limits based on the pellicle standoff and the numerical aperture of the given type of exposure system are given in Table 1. Any departure from these defect limits shall be agreed to between the user and supplier.

5 Requirements

5.1 *Film Adhesive* — Film must be sealed on the entire top of the frame. Seal with a minimum of 50% of the frame width at any location.

5.2 *Frame Adhesive* — Frame adhesive must be continuous and allow no gaps between pellicle frame and adhesive, and between adhesive and photomask after attachment. No part of the frame adhesive may extend beyond the frame wall, and its edges must be free of visually detectable stringers (and particles). Adhesive should form a complete seal between the frame and the mask over a minimum of 60% of the width of the frame.

5.3 *Frame* — Pellicle frame must have no visually detectable machining burrs, discontinuities in anodization, or particles.

5.4 *Light Resistance* — This is expressed by total exposure energy value (mj/cm^2 or j/cm^2) of specified wavelength on pellicle's film until dropping 0.5% of optical transmission (rate) at specified wavelength. Also, the test conditions (half bandwidth of exposure specified wavelength, energy of exposure specified wavelength, exposure conditions, and others) must be clear.

Table 1 Maximum Defect Limits

Characteristics	*Max. No. Allowable*	*Size Counted for Max. No. Allowable*
Non-removable		
Particles	None	>20 µm
Pinholes	None	>limit of detection
Scratches	None	Width >20 µm
Dirt	None	>limit of detection

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. SEMI P6-88
SPECIFICATION FOR REGISTRATION MARKS FOR PHOTOMASKS

1 General Specification

1.1 *Scope*

1.1.1 This specification defines the shape, range of sizes, and general placement of a registration mark for use on all photomasks. Methods of use will be stated in accompanying application notes (to be furnished at a later date).

1.2 *Applicable Documents* — None.

2 Detail Specifications

2.1 *Introduction*

2.1.1 The complete specification for this registration mark is to be agreed upon by the circuit designer, mask maker, and the mask user.

2.2 *Requirements*

2.2.1 This specification covers a defined mark placed photolithographically on photomasks for the express purpose of determining the registration accuracy of one imaged photomask to another imaged photomask within the same set of photomasks.

2.3 *Other*

2.3.1 This mark is not intended to be used for the determination of overlay accuracy of an imaged layer of a photomask onto a maker to any subsequent imaged layers on the same wafer.

3 Guidelines for Shape and Sizes of Registration Mark

3.1 The shape of the mark shall be in the form of a cross (see Figure 1).

3.2 The area of intersection of the horizontal and vertical lines shall be "user-defined." The designer, mask maker, or user may define any shape of geometry within this area. The "user-defined" geometry used shall not exceed the width or height of the area of intersection (see Figure 2).

3.3 The width of both the horizontal and vertical lines shall be equal.

3.4 The length of both the horizontal and vertical lines shall be equal.

3.5 The width and length of the horizontal and vertical lines may vary due to design rules, scaling, process bias, etc. Table 1 lists the design dimensions for each type of photomask. Sections 3.3 and 3.4 are not superceded by this statement.

3.6 Any of the four quadrants created to the outside of the cross shall be defined as "No-Man's Land" and shall not have any geometry or marks placed within them (see Figure 3).

3.7 A field or registration mark (i.e., dark or clear) is user-definable.

3.8 The mark shall be placed as per attached application notes (to be furnished at a later date).

Table 1 Dimensions of Registration Mark For All Mask Types (all dimensions are in micrometers (μm))

Type of Photomask	*Width*	*Length*	*User Defined Area*	*Total Pattern Window*
1× Masters	4 – 8	10 – 15	min. 4 × 4 max. 8 × 8	min. 24 × 24 max. 38 × 38
1× Stepper Reticles	4 – 8	10 – 15	min. 4 × 4 max. 8 × 8	min. 24 × 24 max. 38 × 38
5× Stepper Reticles	8 – 40	20 – 75	min. 8 × 8 max. 40 × 40	min. 48 × 48 max. 190 × 190
10× Stepper Reticles	16 – 80	40 – 150	min. 16 × 16 max. 80 × 80	min. 96 × 96 max. 380 × 380

SEMI P7-0997
METHOD OF VISCOSITY DETERMINATION, METHOD A — KINEMATIC VISCOSITY

1 Scope

1.1 This method, a simplified version of ASTM D 445 and ASTM F 66 is intended for determining the kinematic viscosity of photoresists by measuring the time for a volume of liquid to flow under gravity through a calibrated glass capillary at a fixed temperature. Efflux time is measured in seconds and multiplied by the calibration constant of the viscometer to obtain kinematic viscosity in units of centistokes (cSt). Optionally, kinematic viscosity may be multiplied by the density of the photoresist to obtain dynamic viscosity in units of centipoise (cP). Refer to ASTM D 445 and F 66 for additional information and definitions.

2 Referenced Documents

2.1 *ASTM Standard*[1]

D 445 — Kinematic Viscosity of Transparent and Opaque Liquids (and the Calculation of Dynamic Viscosity)

F 66 — Photoresist Used in Microelectronic Fabrications

3 Apparatus

3.1 *Calibrated Viscometer* — Of the glass capillary type. (A listing of such viscometers is given in Table 1, ASTM D 445.)

3.2 *Constant Temperature Bath* — Equilibrated to 25.0 ± 0.1°C.

3.3 *Viscometer Clamp* — Adjustable to achieve vertical alignment.

3.4 *Thermometer* — Graduated in 0.1°C intervals and calibrated (see ASTM D 445 and ASTM F 66).

3.5 *Stopwatch* — Readable in 0.2 second intervals or better.

3.6 *Chemicals* — Acetone, chromic acid, methyl ethyl ketone, xylene.

4 Procedure

4.1 Confirm that the constant temperature bath is equilibrated to 25.0 ± 0.1°C.

4.2 Select a clean dry viscometer of appropriate viscosity range. Choose the proper tube size for the given viscosity so that the efflux time is greater than or equal to 200 seconds.

4.3 Charge the viscometer with photoresist in the manner dictated by the design of the viscometer and wipe clean.

4.4 Insert the viscometer into the clamp holder in the constant temperature bath. Vertical alignment of the viscometer is essential for proper flow measurement.

4.5 Allow 15 minutes for the sample temperature to equilibrate.

4.6 Use suction or pressure to adjust the level of the test sample to a position in the capillary arm about 5 mm ahead of the first timing mark.

4.7 With the sample flowing freely, measure the time for the meniscus to pass from the first timing mark to the second. Record the time in seconds.

4.8 Repeat the steps in Sections 4.6 and 4.7. (For reverse flow viscometers, use the same or another viscometer and begin with the step in Section 4.3 for the second measurement.)

4.9 The two measurements must agree within 0.5 seconds. If they do not agree, then reject the measurement results.

4.10 After the measurement, the viscometer should be flushed several times with a suitable solvent (methyl ethyl ketone or acetone for typical novolac positive resists or equivalent and xylene for rubber based negative resists or equivalent).

4.11 Dry the tube by blowing dry, filtered air through the viscometer for a few minutes.

4.12 The viscometer should periodically be cleaned with chromic acid to remove trace organic deposits.

5 Calculation

5.1 Average the flow measurements.

5.2 Kinematic viscosity in cTs = Viscometer constant × efflux time in seconds.

5.3 Dynamic viscosity in cP = Photoresist density at 25.0°C in g/mL × kinematic viscosity in cSt.

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohoken, PA 19428-2959

SEMI

SEMI P8-0997
METHOD FOR THE DETERMINATION OF WATER IN PHOTORESIST

1 Scope

1.1 This method is intended for the application of the Karl Fischer titration to the determination of water in photoresists. An electrometric method is used for determining the endpoint. The procedure is applicable to most resists that have polymer and solvent systems fully compatible with Karl Fischer reagent and diluent. The resist manufacturer should be consulted to determine if this procedure can be used with the resist in question.

2 Referenced Documents

2.1 *ASTM Standard*[1]

E 203 — Water by the Karl Fischer Method

2.2 *Reagent Chemicals* — Sixth Edition, American Chemical Society Specifications

3 Apparatus

3.1 Automatic titrator, equipped for Karl Fischer titrations. The titrator should be equipped with a titration vessel with a port for sample entry, desiccated vent tube, and a platinum versus platinum electrode. Mechanical stirring of the titration solvent should be provided for. The manufacturer's suggested operating procedure should be followed, and the endpoint timer set for 20 seconds.

3.2 Hypodermic syringes with lock tip, 0.25 mL and 10 mL.

3.3 Syringe needles, 5 to 8 cm length, 20 and 22 gauge.

3.4 Lint-free tissue.

3.5 Analytical balance, capable of weighing to 0.1 mg.

3.6 *Reagents*

3.6.1 Distilled water.

3.6.2 Methanol, ACS Reagent Grade.

3.6.3 Karl Fischer reagent with a titer of 3.0 (± 5.0) mg of water per ml of titrant. Typical preparation involves a one-to-one dilution of stabilized Karl Fischer reagent with Karl Fischer diluent from the same supplier.

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohoken, PA 19428-2959

4 Procedure

4.1 *Standardization of Karl Fischer Reagent* — The Karl Fischer reagent should be standardized immediately before its use in water determinations.

4.1.1 Install Karl Fischer reagent in the titrator and flush all lines of the titration equipment at least three times.

4.1.2 Fill the titration vessel with enough methanol to cover the electrodes, and seal.

4.1.3 Titrate the methanol automatically with the Karl Fischer reagent to the endpoint (blank).

4.1.4 Draw 0.1 mL of distilled water into a 0.25 mL syringe equipped with a 22 gauge needle. Draw the water from the needle into the syringe by inverting the syringe (needle up) and drawing the plunger downward an additional 1 to 2 cm.

4.1.5 Wipe the needle with lint-free tissue.

4.1.6 Weigh the syringe assembly to the nearest 0.1 mg (W_1).

4.1.7 Inject the water into the titration vessel.

4.1.8 Titrate to the same endpoint used for the methanol blank.

4.1.9 Reweigh the syringe assembly to the nearest 0.1 mg (W_2).

4.1.10 Record the number of milliliters of titrant consumed (V_1).

4.1.11 Calculate the Karl Fischer factor (F):

$$F = \frac{\text{mg water injected}}{\text{mL KF titrant}} = \frac{W_1 - W_2}{V_1}$$

4.1.12 Repeat the standardizing titration twice and calculate the mean value for F from the three values (which should fall within a range of 0.02).

4.2 *Determination of Water*

4.2.1 Fill the titration vessel with enough methanol to cover the electrodes, and seal.

4.2.2 Titrate the methanol automatically with the Karl Fischer reagent to the endpoint (blank).

4.2.3 Flush a dry 10 mL syringe fitted with a 20 gauge needle several times with the sample to be tested. Fill the syringe with 3–5 mL of photoresist sample.

4.2.4 Wipe the needle with lint-free tissue.

4.2.5 Weigh the syringe assembly to the nearest 0.1 mg (W_3).

4.2.6 Inject the sample into the titration vessel.

4.2.7 Titrate to the same endpoint used for the methanol blank.

4.2.8 Reweigh the syringe assembly to the nearest 0.1 mg (W_4).

4.2.9 Record the number of milliliters of titrant used (V_2).

4.2.10 Calculate the water content of the sample.

$$\text{Weight \% } H_2O = \frac{\text{mL KF titrant} \times \text{F}}{\text{sample weight in mg}} \times 100$$

$$= \frac{V_2 \times F}{W_3 - W_4} \times 100$$

4.3 *Remarks* — Photoresists which contain interfering compounds (such as aldehydes and ketones) may require modification of the solvent or titration conditions. For further information, see Section 3.4 of ASTM Standard E 203. For some negative (polyisoprene) photoresists, solubility can be improved by substituting ethylene glycol as the solvent for methanol.

SEMI P9-0298
GUIDELINE FOR FUNCTIONAL TESTING OF MICROELECTRONIC RESISTS

1 Purpose

The purpose of this guideline is to provide a baseline program of test procedures needed to functionally test liquid-developed resists, resist developers, and rinses for microelectronic applications. It can also be used as a guide to evaluate process modifications to such systems. This guideline is intended to be applicable for photo, DUV, x-ray, and electron beam processes.

2 Background

Release of the information in this document was approved by the SEMI Photolithographic Chemicals Committee (Resist Committee) in May 1987. This committee plans to complete and revise the guideline as appropriate. Comments will be welcomed.

3 Scope

Virtually all lithographic fabrication processes vary in some way from location to location, even for the same type of resist. Consequently, it is impossible to provide a stringent evaluation program acceptable to most users. It is, therefore, the aim of this guideline to provide a program of tests and methods that allows variable, but controlled, process differences. In order to maintain a proper baseline control for each process, all tests should be run relative to some internal standard product whose functional characteristics are known and characterized. It is understood that each product is to be run at its own preferred or recommended conditions and that different products maybe evaluated under different conditions. It should also be understood that some properties, variables, or conditions, such as normality, are specific to resist type, such as positive photoresist, and are to be used only where applicable. Further, since this guide is directed to functional testing, it is assumed that any products to be evaluated have passed all relevant chemical and physical testing before such functional testing.

4 Priorities

This guideline has been divided into two separate groups. The first group, called “Sustaining Tests,” includes tests that are necessary for timely adjustments to coating and exposure conditions in order to maintain consistent image dimensions (Tables 1–3). The second group, called “Extended Testing,” includes tests that are required for full evaluation of the resist system (Tables 4–6). These tests may, or may not, be necessary for evaluation of each lot of product, depending on the individual requirements of the user.

SEMI P10-0301
SPECIFICATION OF DATA STRUCTURES FOR PHOTOMASK ORDERS

This specification was technically approved by the Global Mask & Mask Equipment Committee and is the direct responsibility of the North American Microlithography Committee. Current edition approved by the North American Regional Standards Committee on November 22, 2000. Initially available at www.semi.org January 2001; to be published March 2001. Originally published in 1990; previously published February 1999.

This document was entirely rewritten in 2001.

1 Purpose

1.1 These data structure specifications are intended to facilitate the transmittal of mask order data between software systems to allow:

1.1.1 automated order placement by mask customers and to allow the automatic processing of such orders by mask shops, and

1.1.2 automated delivery of actual mask data by mask shops and to allow the automatic processing of such data by mask customers.

1.2 By using these standardized structures, software written independently for either mask customers or mask shops should be able to communicate unambiguously with software written by other parties.

2 Scope

2.1 This structure only defines the data format for the transmitted file. No particular database or programming language is specified by this standard. The data file is to be transmitted as an ASCII file. As such, it is compatible with the SECS-II standard.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety health practices and determine the applicability or regulatory limitations prior to use.

3 Limitations

3.1 For a given customer, all pattern file names must be unique. (i.e., Pattern files which are different may not have the same name.)

3.2 For a given customer, all job file names must be unique. (i.e., Job files which are different may not have the same name.)

3.3 For a given customer, each mask set must have a unique identification.

3.4 For a given customer, each magnetic tape or other physical media delivered to the mask shop must have a unique identification.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI P1 — Specification for Hard Surface Photomask Substrates

SEMI P2 — Specification for Chrome Thin Films for Hard Surface Photomasks

5 Terminology

5.1 See Section 8.

6 Instructions and Conventions

6.1 Each record in the file will be composed of a specific keyword identifier followed by one or more data values, and will be terminated by a carriage return and/or linefeed.

6.2 Only records which are required to specify the order need to be included in the transmitted <mask_order> file, but each record included must appear in the sequence shown in the syntax specification.

6.3 Subsequent modifications or additions to the mask set require transmittal of all the information for the specific masks involved, including previously transmitted keywords and data fields if they still apply. Masks previously ordered which are not affected by the new order transmission may have their <mask_definition>, <mask_group> or <mask_set> omitted as appropriate.

6.4 Options are specified hierarchically such that those specified at a higher level are the default for all masks below, unless overridden at a lower level. The hierarchy is such that mask set options are overridden by mask group options, followed by mask definition, cell definition, cell instance, pattern group definition, and pattern definition.

6.5 Mask groups describe sets of masks which are similarly constructed. In simple cases there will be only one mask group per mask set. Multiple mask groups will be needed to describe mix-and-match sets, or for situations within a mask set where different features are required on some masks.

6.6 Pattern group definitions are intended for patterns which are similarly placed on all or most masks within a mask group (e.g., primary pattern files or test pattern files).

6.7 Cell definitions describe the construction of clusters of pattern groups and/or other cells. The PLACEMENT_TOP_CELL under a mask group describes the overall layout of the cells on all masks within the mask group.

6.8 Within a given mask set, each mask must have a unique identification (MASK_ID), independent of any titles on the mask.

6.9 Masks which require multiple writing operations (such as phase shift masks) will find those MASK_ID's identified with the same group number by the MULTIWRITE keyword.

6.10 The MASK_ID's defined under a mask group specify the masks to be built. The MASK_ID's also identify which patterns are to appear on the mask. A pattern is placed on the mask if and only if the MASK_ID matches the LEVEL_ID of a pattern referenced under the mask group's PLACEMENT_TOP_CELL.

6.11 <cell instance> and <pattern group instance> LOCATION's position the center of the patterns relative to the center of the CELL_ID referencing them. The cell referenced by the PLACEMENT_TOP_CELL is positioned at the center of the mask.

6.12 Job file data may be supplied in place of cell and pattern group data. In this case, the MASK_ID is understood to correspond to JOB_LEVEL in JOB_NAME.

6.13 Location of reference marks, mask titles and vendor-supplied barcodes are relative to the center of the mask. The coordinates and directions refer to right-handed, rectangular (Cartesian) coordinates, applied to the substrate being written.

6.14 All data in the structure will be in ASCII. The keyword in each record must include only upper case alphabetic characters and underscore.

6.15 Records (keyword, data value, comment and new line) may not exceed 256 characters. Some records may be repeated (e.g., BUSINESS_ADDRESS) in order to allow for longer field requirements; these are explicitly indicated in the syntax specification.

6.16 Comments may be included in records by preceding them with an exclamation point (!). Any data following an exclamation point and preceding a carriage return and/or linefeed will be ignored. Such comments are included in the 256 character record limit. If a record starts with an exclamation point, the entire record will be ignored. Only printable ASCII characters (plus spaces and tabs) are permitted in comments. Comments are for development and diagnostic purposes only. In commercial use, comments may always be ignored by the recipient without consequence. On the other hand, ADDITIONAL_..._INFO records must be evaluated by the recipient and applied to the masks being ordered, and may justify delay in mask delivery.

6.17 Spaces or tabs preceding the keyword will be ignored. At least one space or tab must precede the data field. Spaces and tabs imbedded in alphanumeric data fields will be preserved. Spaces or tabs may not be imbedded within numeric data values, but may be used to separate data values in multi-value data fields. At least one comma must appear between adjacent data values in multi-value data fields; more than one comma may not appear between adjacent data values. Spaces or tabs trailing the last data value in a data field will be ignored.

6.18 All numeric record values which require units will be in metric unless otherwise specified in Section 8. Units of length or position will be in microns unless otherwise specified.

6.19 Dates will be in the alphanumeric format DD-MMM-YYYY, where MMM will be the first 3 letters of the English spelling of the month. Times will be in the format HH:MM:SS OR HH:MM. Within the transmitted file, times and dates will always be Greenwich mean time.

6.20 Sizing to achieve a CD_TARGET from a CD_DATA must be applied to all pattern files hierarchically affected by the CD_TARGET record.

6.21 Since complex data manipulation operations are composed of simple binary and unary operations, intermediate files will need to be named. These names may be comprised of any printable ASCII characters, and must be unique within all revisions of the <mask_set>.

6.22 Binary data manipulation operations expect operands (input pattern files) to align center-to-center. This requires that DATA_PATTERN_WINDOW be defined for patterns which do not contain an explicit record of file extents.

6.23 All references to horizontal (or "x") and vertical (or "y") correspond to normal Cartesian coordinates and assume the rotational orientation of the glass when the mask was written.

6.24 All <shippable_data> keywords will be followed by <ship_to> specifying the destination and/or method of transmission for the transmitted data. Whenever applicable, the SEMI_MASK_DATA file (see Section 7.5) should be sent accordingly if electronic transmission is specified.

6.25 <shippable_data> keywords which require reference to specific mask feature locations will reference CD_SITE_ID and/or REGISTR_MARK_ID which must be unique for each location within all transmissions of <mask_order> for a given MASK_SET_ID.

7 Syntax Specification

The following specifies the syntax for the mask order structures. The record order is specific; records must appear in the sequence shown. Terminology for the individual records and their allowed data values are specified in Section 8.

7.1 *Syntax Symbol Definition* — The lower case syntactic names within < > are used to refer to collections of records. The use of { } around records or collections of records means an arbitrary number of repetitions of the records, including none at all. The use of [ ] around a record or collection of records means that the collection is optional.

7.2 *Record Syntax* — A keyword is followed by a data field which is followed by an optional comment. The record is terminated by a carriage return and/or linefeed. Each of these elements may be preceded by any combination of spaces or tabs, which will be ignored. At least one space or tab is required preceding the first data value in the record. An exclamation point (!) is required to initiate a comment. Exclamation points, carriage returns, and linefeeds are not allowed in keywords, data values or comments. Note that a record consisting of a comment only is also allowed. The syntax for individual records is defined as:

<record> = [{ <separator>} <keyword>

<separator> { <separator>} <data_field>]

[{ <separator>} ! <comment>]

{ <separator>} <new_line>

where “separator” is a space or a tab, “comment” is any string of printable ASCII characters (plus spaces and tabs), and “new_line” is a carriage return, linefeed or both.

7.3 *Multi-value Data Field Syntax* — When data_field is for (x,y) pairs or (x1,y1,x2,y2) double pairs (see Section 8), the individual values must be separated by a comma and any combination of spaces or tabs. One comma is required between each data_value, but not more than one comma. Two commas without an intervening data value are not permissible.

(x,y) = value { separator} comma { separator} value

(x1,y1,x2,y2) = (x1,y1) { separator} comma { separator} (x2,y2)

For data manipulation operations, three- and six- value data fields are also allowed:

(x,y,z) = (x,y) { separator} comma { separator} (z)

(x,y,x1,y1,x2,y2) = (x,y) { separator} comma { separator} (x1,y1,x2,y2)

7.4 *Mask Order Structure Syntax* — The following syntax definition uses the upper case keyword to represent the permissible applications of the corresponding data record within the mask order structure.

8 Terminology and Usage

8.1 Values in parentheses indicate the only acceptable alternative data values for the record and must be transmitted exactly as shown. (x,y) indicates the acceptable data value must be an ordered pair of dimensions, coordinates, repeat counts, filenames, or other parameters. (x,y,z) indicates an ordered triple. (x1,y1,z1) indicates a window with two ordered pairs, (x1,y1) and (x2,y2), describing the lower left and upper right corners respectively. Records without specified alternative values may have any appropriate data value.

ADDITIONAL_MASK_INFO

Any information necessary to specify the overall mask set which cannot be specified elsewhere in the order structure; must be brought to the attention of mask vendor personnel.

ADDITIONAL_MASK_SET_INFO

Any information necessary to specify the overall mask set which cannot be specified elsewhere in the order structure; must be brought to the attention of mask vendor personnel.

ADDITIONAL_MILESTONE_INFO

Text for the vendor to supply additional information regarding the status of the mask.

ADDITIONAL_PATTERN_INFO

Any information necessary to specify the pattern(s) which cannot be specified elsewhere in the order structure; must be brought to the attention of mask vendor personnel.

AND

(x,y,z) Name of file (x) to be formed by the logical intersection of the digitized geometries in file (y) and file (z). The extents of the pattern file (x) will be the same as for file (y).

APPROVAL_REQD

If present, indicates that no mask(s) are to be written until the approval is explicitly granted by the customer. The alphanumeric data field describes the items to be approved.

ARRAY_CENTER

Center of circular array limit, relative to the center of the mask.

ARRAY_DIAMETER

Diameter of circular array limit to be applied to pattern files.

ARRAY_DIAMETER_INCLUSIVE

(T or F) If T, then die which are at least partially included within the circular array limit must be included in the array. If F, then only die which are wholly included within the circular array limit may be included in the array.

ARRAY_PLOT_SCALE

Numeric scale of array map

AUTO_INSPECTION_REQD

(T or F) Automated inspection of the mask for defects is required.

BARCODE_LOCATION

(x,y) Location to place the center of the vendor-generated barcode.

BARCODE_ROTATION

(0,90,180, or 270) Degrees the barcode is to be rotated counterclockwise (before mirroring).

BARCODE_TEXT

Text to be used by the vendor to build the barcode.

BARCODE_TYPE

(ASM, ASET, CANON, GCA, NIKON_STD or NIKON_CUBE37, and others on request) Encoding system to be used by the vendor to build the required barcode.

BILLING_ADDRESS

Address for billing.

BILLING_CONTACT

Name of person to contact for billing purposes.

BILLING_EMAIL

Internet address for BILLING_CONTACT.

BILLING_FAX

Phone number for facsimile machine of BUSINESS_CONTACT.

BILLING_PHONE

Phone number for BILLING_CONTACT.

BLANKET_PO_NUMBER

Alphanumeric blanket purchase order number.

BOTTOM_PELLICLE_TYPE

Alphanumeric brand and model of acceptable pellicle for the glass side of the mask. If multiple pellicles are listed, they are listed with the most preferred first and then in declining preference.

BUSINESS_ADDRESS

Address of person placing the order.

BUSINESS_CONTACT

Name of person placing the order.

BUSINESS_EMAIL

Internet address for BUSINESS_CONTACT.

BUSINESS_FAX

Phone number for facsimile machine of BUSINESS_CONTACT.

BUSINESS_PHONE

Phone number for BUSINESS_CONTACT.

BUTTING_ERROR

Maximum misalignment of features due to stitching of adjacent fields in the segmented writing of a mask.

BUTTING_ERROR_METHOD

Alphanumeric description of the method to be used to measure butting error.

CD_CORRELATION_ID

Alphanumeric date or other identification of the vendor/customer correlation test to be used in measuring CDs.

CD_DATA

Size of critical dimension feature in data as supplied in the pattern file.

[CD_DENSE]

(T or F) Region surrounding cd feature is dense geometry.

CD_DEVIATION_FROM_MEAN

Maximum acceptable deviation of any of the customer-required CD measurements from the mean of those measurements.

CD_DEVIATION_FROM_TARGET

Maximum acceptable deviation of any of the customer-required CD measurements from the CD_TARGET.

CD_DIGITIZED

(T or F) If T, critical dimension in pattern is digitized data.

CD_DRAWING

The uniquely identified (for each customer) document which shows the CD structure itself, and may show the place within the CD which are to be measured.

CD_EQUIP_REQD

Alphanumeric identification of acceptable equip-ment for measuring critical dimensions.

CD_FEATURE

Text describing the feature to be used for CD measurement.

CD_ISOLATED

(T or F) CD feature has no other geometry nearby.

CD_LOCATION_DRAWING

The uniquely identified (for each customer) document which shows the location of the CD structure.

CD_MATRIX_FILE_NAME

Alphanumeric name of file to be used for critical dimension measurement locations. It is not to be used in conjunction with MASK_CD_LOCATION or PATTERN_CD_LOCATION within the same START_CD to END_CD set.

CD_MATRIX_FILE_FORMAT

(MF2, MF3, KMS and others on request)

CD_MEASURE_DIE

In combination with the associated <placement> definition, specifies the die to be used for CD measurement.

CD_ORIENTATION

(VERTICAL or HORIZONTAL) Direction in which the CD feature is to be scanned for measurement.

CD_RANGE

Maximum acceptable variation of all measured critical dimensions of same nominal size, same tone and same orientation, relative to each other.

CD_REFERENCE_ONLY

(T or F) If T, indicates that the CD location is to be measured and the data transmitted to the customer (if requested by SHIP_CD_DATA_), but that deviations in its measured value due to mask processing would NOT be cause for mask rejection. (This does not exempt mishandling of the data in pattern preparation from being a cause for mask rejection.)

CD_SITE_ID

Unique alphanumeric identifier of each critical dimension location within MASK_SET_ID to identify individual cd locations when using <mask_data>. If the same coordinates apply to locations on different masks within the mask set, they may have the same CD_SITE_ID, but it is not mandatory. If CD_SITE_ID is used with a PATTERN_CD_LOCATION, it will be associated with as many mask locations as the cell has instances. (See MEASURED_ CD_SITE _ID for more information.)

CD_STD

(NBS, NIST, ROGER_SHERMAN, CUSTOMER, and others on request) reference standard to be used to correlate critical dimension measurements.

CD_TARGET

Desired final size of critical dimension feature on mask.

CD_THREE_SIGMA

Maximum acceptable 3-sigma deviation of all measured critical dimensions to the the mean of all measured critical dimensions

CD_TOLERANCE

Maximum acceptable deviation of the mean of all measured critical dimensions to the CD_TARGET

CD_TONE_CLEAR

(T or F) If T, critical dimension feature on mask is clear.

CD_XY_DEVIATION

Maximum deviation, on a site-by-site basis, of a horizontal critical dimension to a vertical critical dimension. The two critical dimensions at each site must be the same size in the pattern data.

CD_XY_TOLERANCE

Maximum acceptable deviation of the mean of all measured horizontal critical dimensions to the mean of all measured vertical mask critical dimensions. Critical dimensions at all sites must be the same size in the pattern data.

CELL_ID

Name of the cell which follows; must be used in all references within this MASK_SET_ID to this cell definition.

CELL_INSTANCE

(text) Identifies CELL_ID to be placed by the following location information.

CELL_REGISTR_MARK

(x,y) Location of initial registration reference mark, relative to center of cell (before mirroring or scaling).

CENTRALITY

Maximum misplacement in millimeters of all patterns as a group, relative to the nominal center of the mask. The nominal center is determined using the bottom and left edges (chrome side up) and assumes nominal substrate dimensions. (See SEMI P1.)

CHECKSUM

For <mask_order>, an ASCII 16 bit crc checksum encompassing all records from START_ORDER through END_ORDER, inclusive. For <mask_data>, an ASCII 16 bit crc checksum encompassing all records from START_MASK_DATA through END_MASK_DATA, inclusive. (See COMPUTING THE CHECKSUM, Section 9.)

CLEAR_INTERNAL_WINDOW

(x,y,x1,y1,x2,y2) Name of file (x) to be formed from file (y) by removing all digitized data within the window described by (x1,y1,x2,y2). The extents of the pattern file (x) will be the same as for file (y).

COMPACT_LABEL

Identification of customer-supplied label to use on shipping compact.

CUSTOMER

The name of the company placing the order.

DARK_INTERNAL_WINDOW

(x,y,x1,y1,x2,y2) Name of file (x) to be formed from file (y) by completely digitizing the entire area within the window described by (x1,y1,x2,y2). The extents of the pattern file (x) will be the same as for file (y).

DATA_COMPRESSION

(ZIP, ZOO, GZIP, Z, NONE, BINHEX) Compression algorithm used for transmitted data.

DATA_CONSOLIDATION

(BACKUP, TAR, GNUTAR, ZIP, NONE Consolidation method used for transmitted data.

DATA_ENCRYPTION

(PGP, NETWIZARD, USER, HARDWARE, NONE) Encryption algorithm used for transmitted data.

DATA_CHECKSUM

(integer) To be used to verify integrity of transmitted data.

DATA_CHECKSUM_TYPE

(text) Algorithm used to generate DATA_CHECKSUM.

DATA_DATATYPE

(integer) Sublevel to a DATA_LAYER_ID for GDS-II data.

DATA_DENSITY

(800BPI, 1600BPI or 6250BPI for 9_TRACK_-TAPE DATA_MEDIUM; HIGH or LOW for 4MM_DAT or 8MM_DAT DATA_MEDIUM) for magnetic tape density.

DATA_FILE_NUMBER

For GDS-II, Mann or Electromask data, this is the file number on the physical medium.

DATA_FILE_SIZE

Size of the file in bytes.

DATA_FORMAT

(MEBES, MEBES_MODE_5, RDOS = RDOS dump, VAX = VAX backup, GDS-II = GDS-II stream, CIF = Cal Tech Intermediate Format, DXF = Autocad output, APPLICON, MANN_3000, MANN_3600, ELECTROMASK, DOS, UNIX, APPLE, TAR, and others on request) Physical medium format.

DATA_ID

The required identifying "name" for a physical volume of data. The name must match the label visible on the outside of the volume and must be unique among all physical volume names sent by a customer to a vendor.

DATA_JOB_NAME

For E-beam data, this is the name of the job file to be expected in DATA MEDIUM.

DATA_LAYER_ID

Layer to use within DATA_TOP_CELL.

DATA_LOCATION

Alphanumeric site where the data file may be found.

DATA_MEDIUM

(9_TRACK_TAPE, 4MM_DAT, 8MM_DAT, 1/4_INCH_CARTRIDGE, MODEM, FLOPPY, EMAIL, VPN, FTP, RCP, CDR, CDRW, HARDDRIVE ZIPDRIVE, JAZZDRIVE, FLOPPY100MB) Data transfer medium used for delivering pattern files, job files and measure files.

DATA_OFFSET

For optical masks only, the (x,y) shift to be applied to the data in building the mask.

DATA_PATTERN_NAME

For numbered files in a data volume, this is the pattern name to be applied to the file specified by the succeeding DATA_FILE_NUMBER and/or DATA_TOP_CELL and/or DATA_LAYER_ID. For E-beam, data, this is the name of the pattern file to be expected on the physical volume.

DATA_PATTERN_WINDOW

(x1,y1,x2,y2) Establishes the extents of the pattern file in the coordinate space as received. (x1,y1) identifies the lower-left corner; (x2,y2) identifies the upper-right corner.

DATA_SCALE_FACTOR

(x,y,z) Name of file (x) to be formed by (de)magnifying both the geometries and the overall pattern file extents of the file (y) by the positive, numeric (de)magnification factor (z).

DATA_TOP_CELL

Top cell or structure of the design.

DATABASE_AREA

(x1,y1,x2,y2) Unscaled, unmirrored coordinates of window for database inspection, lower left and upper right corners, relative to the center and coordinate system of the pattern or cell or, if a <mask_option>, relative to the center of the mask.

DATABASE_FILE_NAME

Name of database file to use for database inspection.

DATABASE_INSPECTION

(T or F) If T, database inspection is required.

DATABASE_JOB_LEVEL

Mask level of customer-supplied job file to use for database inspection.

DATABASE_JOB_NAME

Customer-supplied job file to use for database inspection. Should be omitted if customer does not supply job file.

DATABASE_LAYER

Layer to be used if DATABASE_SOURCE is GDS-II.

DATABASE_SOURCE

(MEBES, PG, GDS-II, KLARIS, UNDERIVED, and others on request) Data source to be used when database inspection is required. KLARIS indicates that KLARIS data was supplied by the customer. UNDERIVED indicates the customer-supplied data prior to vendor-performed data manipulation is to be used to produce the inspection data. GDS-II indicates that the GDS-II data is being supplied for database inspection, in addition to the customer-supplied MEBES or PG data to be used to write the mask.

DATABASE_TOP_CELL

Top cell to be used if DATABASE_SOURCE is GDS-II.

DATABASE_UNIT

Grid size to be used for fracturing DATABASE_-SOURCE into inspection data, as required by some inspection systems.

DATABASE_WITH_JOB

(T OR F) Database inspection must use job file (DATABASE_JOB_NAME and DATABASE_JOB_LEVEL if supplied by customer) to consolidate pattern files.

DEFECT_COUNT

Integer maximum allowable number of defects within the INSPECTION_AREA.

DEFECT_COUNT_REP

Integer maximum number of repeating defects within the INSPECTION_AREA.

DEFECT_DENSITY

Maximum allowable number of defects per square centimeter within the INSPECTION_AREA.

DEFECT_EQUIP_REQD

Alphanumeric identification of acceptable equip-ment for defect inspection.

DEFECT_INSP_MODE

Alphanumeric operating mode for DEFECT_-EQUIPMENT_REQD.

DEFECT_SETUP_FILE_NAME

Alphanumeric name of setup file for DEFECT_-EQUIP_REQD.

DEFECT_SIZE

Maximum dimension of smallest unacceptable defect—all types.

DEFECT_SIZE_CL

Maximum dimension of smallest unacceptable clear defect.

DEFECT_SIZE_CL_ADJ

Maximum dimension of smallest unacceptable clear, non-repeating edge defect.

DEFECT_SIZE_CL_ADJ_REP

Maximum dimension of smallest unacceptable clear, repeating edge defect.

DEFECT_SIZE_CL_ISO

Maximum dimension of smallest unacceptable clear, repeating isolated defect.

DEFECT_SIZE_CL_ISO_REP

Maximum dimension of smallest unacceptable clear, non-repeating isolated defect.

DEFECT_SIZE_DK

Maximum dimension of smallest unacceptable dark defect.

DEFECT_SIZE_DK_ADJ

Maximum dimension of smallest unacceptable dark, non-repeating edge defect.

DEFECT_SIZE_DK_ADJ_REP

Maximum dimension of smallest unacceptable dark, repeating edge defect.

DEFECT_SIZE_DK_ISO

Maximum dimension of smallest unacceptable dark, non-repeating isolated defect.

DEFECT_SIZE_DK_ISO_REP

Maximum dimension of smallest unacceptable dark, repeating isolated defect.

DEFECTIVE_DIE_DENSITY

Maximum allowable number of die with defects per square centimeter within the INSPECTION_AREA.

DEFECTIVE_DIE_COUNT

Integer maximum allowable number of die with defects within the INSPECTION_AREA.

DEFECTIVE_DIE_COUNT_REP

Integer maximum number of repeating defective die within the INSPECTION_AREA.

DELIVERABLE_MASK

(T or F) If F, the mask is to be held internally by the mask shop for the production of other deliverable masks. For a MASK_ID with MULTIWRITE, only the final write and process step MASK_ID within the multiwrite group may have DELIVERABLE_MASK = T.

DESIGN_RULE

Numeric data field indicates the nominal minimum dimension of wafer geometries.

DIE_TO_DIE_INSPECTION

(T or F) If T, die-to-die inspection is required.

DIGITIZED_DATA_DARK

(T or F) If T, the image of digitized data is to be opaque on the mask. If F, the image of digitized data is to be clear.

DROPOUT

(x,y) Row and column of pattern or cell placement which is to be omitted in the array. These array coordinates are rectangular (even if the actual written array is non-rectangular), with the origin at the lower left of the array (before mirroring).

DUE_DATE_TIME_COMMITTED

(date,time) For delivery (at customer) committed by vendor.

DUE_DATE_TIME_REQUESTED

(date,time) Requested for delivery (at customer).

DXF_ANGLE

(integer) To be used if DATA_FORMAT is DXF.

DXF_UNIT

(integer) To be used if DATA_FORMAT is DXF.

EDGE_RAGGEDNESS

The subjective impression of irregular deviations of a visual edge from an intended smooth curve or straight line. (See F127).

EDGE_ROUGHNESS

The (numeric) maximum value of edge roughness, based on physical measurements.

ELAPSED_TIME

Numeric hours between masking steps in the wafer fab. Used in conjunction with LAYER_PRIORITY, provides scheduled due dates based on the delivery of each previous mask. No mask may have both ELAPSED_TIME and DUE_DATE_REQUESTED. See LAYER_PRIORITY.

ELAPSED_TIME_COMMITTED

Numeric hours for delivery (at customer) committed by vendor.

EMAIL_ADDRESS

Internet address.

END_BARCODE

(text) must match data field of START_BARCODE.

END_CD

Alphanumeric data field must match data field of START_CD.

END_CD_MEASUREMENTS

(text) must match data field of START_ CD_MEASUREMENTS.

END_CELL

Must match data field of CELL_ID for which data is complete.

END_ CELL_INSTANCE

(text) must match data field of CELL_INSTANCE.

END_CELL_INSTANCE_OPTIONS

Must match data field of CELL_INSTANCE for which pattern options are complete.

END_CELL_OPTIONS

Must match data field of CELL_ID for which options are complete.

END_ DATA_MANIPULATION

(text) must match data field of START_DATA_MANIPULATION.

END_DATA_MEDIUM

Must match data field of DATA_MEDIUM for which data is complete.

END_ DATA_PATTERN_ NAME

Must match data field of DATA_PATTERN_NAME.

END_DEFECT_DEFINITION

(text) must match data field of START_DEFECT_DEFINITION

END_DEFECT_MEASUREMENTS

(text) must match data field of START_DEFECT_MEASUREMENTS.

END_FTP_HOST

Must match data field of FTP_HOST_NAME.

END_MASK

Must match data field of MASK_ID for which data is complete.

END_MASK_DATA

Must match data field of START_MASK_DATA.

END_MASK_GROUP

Must match data field of MASK_GROUP_ID for which data is complete.

END_MASK_GROUP_OPTIONS

Must match data field of MASK_GROUP_ID for which options are complete.

END_MASK_SET

Must match data field of MASK_SET_ID for which data is complete.

END_MASK_SET_OPTIONS

Must match data field of MASK_SET_ID for which options are complete.

END_MEASURED_CD_SITE

Must match data field of MEASURED_CD_SITE_ID.

END_MEASURED_REGISTR_MARK

Must match data field of MEASURED_REGISTR_MARK_ID.

END_OPC

Must match data field of START_OPC.

END_ORDER

Must match data field of START_ORDER for which data is complete.

END_PATTERN_DEFINITION

Must match data field of LEVEL_ID for which data is complete.

END_PATTERN_GROUP

Must match data field of PATTERN_GROUP_ID for which data is complete.

END_ PATTERN_GROUP_INSTANCE

Must match data field of PATTERN_GROUP_INSTANCE.

END_PATTERN_GROUP_OPTIONS

Must match data field of PATTERN_GROUP_ID for which options are complete.

END_PATTERN_OPTIONS

Must match data field of START_PATTERN_OPTIONS

END_PHASESHIFT

Must match data field of START_PHASESHIFT.

END_PLACEMENT

Must match data field of START_ PLACEMENT.

END_REGISTR

Must match data field of START_ REGISTR.

END_ REGISTR _MEASUREMENTS

Must match data field of START_REGISTR_MEASUREMENTS.

END_SHIP_ARRAY_PLOT

Must match data field of SHIP_ARRAY_PLOT.

END_SHIP_FILM

Must match data field of SHIP_ FILM.

END_SHIP_TO

Must match data field of START_SHIP_TO.

END_ SHIPPABLE_DATA

Must match data field of START_SHIPPABLE_DATA.

END_TITLE

(title number) Indicates end of keywords for a specific title. Must match data field of START_TITLE for which data is complete.

END_VENDOR_INFO

Must match data field of START_VENDOR_INFO.

ENGINEERING_ADDRESS

Address for delivery of shippable engineering data.

ENGINEERING_CONTACT

Name of person to contact for technical questions.

ENGINEERING_EMAIL

Internet address for ENGINEERING_CONTACT.

ENGINEERING_FAX

Phone number for facsimile machine of ENGINEERING_CONTACT.

ENGINEERING_PHONE

Phone number for ENGINEERING_CONTACT.

ESTIMATED_ARRIVAL

The date and time when the vendor predicts MASK_ID will be delivered to the customer, based on the MILESTONE most recently completed.

ESTIMATED_ARRIVALS

(T or F) If T, the vendor is requested to use <mask_data> to supply a prediction of the delivery date and time when MASK_ID will be delivered to the customer, based on the MILESTONE most recently completed. ESTIMATED_ARRIVAL will be transmitted each time <mask_data> is required by either MILESTONES or PERIODIC_UPDATES. If neither have been requested, then ESTIMATED_ARRIVAL should be transmitted daily.

ETCH_DEPTH_ERROR

Maximum allowable deviation (in angstroms) of any etch depth measurement from ETCH_DEPTH_TARGET.

ETCH_DEPTH_RANGE

Maximum acceptable variation (in angstroms) of all etch depth measurements, relative to each other.

ETCH_DEPTH_TARGET

Desired mean etch depth in angstroms.

ETCH_DEPTH_TOLERANCE

Maximum acceptable deviation (in angstroms) of the mean of all measured critical dimensions to the ETCH_DEPTH_TARGET.

EXTERNAL_WINDOW

(x,y,x1,y1,x2,y2) Name of file (x) to be formed from file (y) by removing all digitized data outside the window described by (x1,y1,x2,y2). The extents of the pattern file (x) are thus defined by the window.

FIGURE_COUNT

Total number of geometries which are expected in the pattern file. If this is incorrect, the mask will not be written until it is corrected.

FILE_DATE_TIME

(x,y) Date and time of transmission of mask order. Format will be as in Section 6.19.

FILM_COLOR

Color to be used for the mask film.

FILM_NORMAL_TONE

(T or F) If T, digitized data will be dark.

FILM_SCALE

Numeric scale of the film of the mask image.

FILM_SIZE

(x,y) Size in inches of the film.

FLATNESS

(2, 5, 10, or 20) Flatness within quality area (see SEMI P1).

FRACTURING_SCALE

For optical data (Mann or Electromask) only, this is the scale factor to use in fracturing the data to E-beam format.

FTP_HOST_NAME

Domain of the FTP host, either in the form n.n.n.n where n is an integer from 0 to 255, or in an equivalent text name if such is supported by the FTP site.

[FTP_LOGIN]

The login name for an FTP account. If an anonymous FTP is used, the data field will be "anonymous".

[FTP_PASSWORD]

Password for FTP account.

[FTP_DIRECTORY]

Name of target directory for FTP data.

[FTP_MODE]

(ASCII, BINARY or AUTO) Data type for FTP data. If absent, default is BINARY.

GLASS_SIZE

(2.5/60, 3/60, 3.5/60, 4/60, 4/90, 4/250, 5/60, 5/90, 5/250, 6/90, 6/120, 6/150, 6/250, 7/120, 7/150, 7/250, 7.25R/150 or 9/350) Nominal edge length (in inches) and thickness (in mils) of square substrate; 7.25R/150 is a round substrate. (See SEMI P1.)

GLASS_TYPE

(HTE, LTE, ULTE, WC, or SL) High-, low-, and ultralow thermal expansion glass (see SEMI P1.) WC and SL indicate White Crown and soda lime glass.

GOOD_FIELDS

Specifies the 1X reticle fields which must pass inspection criteria and is applied to the cells immediately instanced by the preceding CELL_ID. Fields are referenced by numbers assigned from left to right according to their position on the mask, chrome side up. For example, for a mask with 5 fields, the fields would be:

1 2 3 4 5

The required good fields are specified by any logical combination of field numbers, "AND", "OR", and parentheses. In the above example, "(1 OR 2) AND (3 OR 4) AND 5" would require that either 1 or 2 be good, and either 3 or 4 be good, and that 5 be good. No logical precedence is assumed; precedence is defined only by parentheses. This keyword applies only to 1X reticles.

GUIDES_REQD

(STANDARD, WIDE or BOTH) Applies to 1X reticles only.

INSPECT_ALL_SITES

If T, all placements of patterns under this <cell_instance> or <pattern_instance> require inspection, regardless of the number of inspection tool setups necessary to do so.

INSPECT_THROUGH_PELLICLE

(T or F) If T, the mask must be inspected through the pellicle and the <defect_definition> and <database_inspection> keywords to be used must follow the INSPECT_THROUGH_PELLICLE keyword. Unpellicized inspection may be separately defined and would precede the INSPECT_THROUGH_PELLICLE keyword.

INSPECTION_AREA

(x1,y1,x2,y2) Unscaled coordinates of window for defect inspection, lower left and upper right corners, relative to center of mask, pattern or cell (chrome side up for masks, unmirrored for patterns or cells).

INPECTION_AREA_EXCLUDE

(x1, y1, x2, y2) Unscaled coordinates of window to be excluded from defect inspection. (See INSPECTION_AREA.)

INSPECTION_SETUP_FILENAME

Alphanumeric name of setup file for defect inspection equipment.

INSP_DATABASE_DATA_FORMAT

Alphanumeric description of format for SHIP_-INSP_DATABASE_DATA.

INSPECTION_REF_LOCATION

(x,y) Location of reference mark for defect inspection, relative to the center of the the substrate (chrome side up).

JOB_FORMAT

(MEBES, EEBES, ATEQ, and others on request) Format of preceding job file.

JOB_LEVEL

Level of above JOB_NAME to be used to make mask.

JOB_NAME

Name of job file to be used to make mask(s).

LAYER_PRIORITY

Sequence number in which masks are needed. Together with ELAPSED_TIME determines the mask delivery schedule. The first mask (LAYER_PRIORITY=1) is due within its ELAPSED_TIME from the time it is ordered or released; the second mask is due within its ELAPSED_TIME from when the first mask was due, or from when the first mask was delivered, whichever is later; and so on.

LEVEL_ID

Numerical indicator of which masks within the mask set will include this pattern. When a MASK_ID in a MASK_GROUP, which references this PATTERN _GROUP_ID, matches this LEVEL_ID, this pattern will appear on the mask. When LEVEL_ID is “A”, the pattern will appear on all masks which reference the pattern group. A given LEVEL_ID value may appear only once in any pattern group. Appearance of “A” as a LEVEL_ID value precludes any other patterns from the pattern group.

LINE_ITEM_NUMBER

Integer line item number relative to PO_NUMBER.

LOCATION

(x,y) Location of the center of the initial pattern or cell, relative to center of the preceding CELL_ID (before mirroring).

LOCATION_SPEC

Alphanumeric identification of customer-supplied specification for pattern or cell placement.

MASK_CD_LOCATION

(x,y) Location of critical dimension feature relative to the center of the mask (chrome side up).

MASK_COATING

(HIGH_REFLECTIVE_CHROME, MEDIUM_RE-FLECTIVE_CHROME, LOW_REFLEC-TIVE_CHROME, SEE_THROUGH_CHROME, IRON_OXIDE, CHROME_OXIDE, EMULSION, MOSI, TISIN, ZRSI) or in the case of other coatings, an alphanumeric description. (See SEMI P2.)

MASK_GROUP_ID

Name of the mask group which follows; must be used in all references within this MASK_SET_ID to this mask group.

MASK_ID

Unique integer identifier of each mask within mask set. All patterns referenced by the MASK_-GROUP_ID's PLACEMENT_TOP_CELL whose LEVEL_IS's match this MASK_ID will appear on the mask. When LEVEL_IS is “A”, the pattern will appear on all masks whose PLACEMENT_-TOP_CELL references the pattern group.

MASK_NAME

Name used by customer for mask, to be used to cross-reference MASK_ID to customer's internal tracking system. This is for the customer's use only and will be completely ignored in the automatic processing of the mask order.

MASK_REGISTR_MARK

(x,y) Location of initial registration reference mark, relative to center of substrate (chrome side up).

MASK_REGISTR_MARK_LOCATION

(x,y) Location of individual registration mark, relative to center of substrate (chrome side up), based on <mask_order> information.

MEASURED_REGISTR_MARK_LOCATION

(x,y) Location of individual registration mark, relative to center of substrate (chrome side up), as measured by the vendor.

MASK_SET_ID

The “name” of the mask set, often the device name or number. This must be used in all future references to this mask set and must be unique among mask sets ordered by the customer.

MASK_SET_NAME

Name used by customer for mask set, to be used to cross-reference MASK_SET_ID to customer's internal tracking system. This is for the customer's use only and will be completely ignored in the automatic processing of the mask order.

MASK_SET_VERSION

Name used by customer for versions of the mask set, to be used to cross-reference MASK_SET_ID to customer's internal tracking system. This is for the customer's use only and will be completely ignored in the automatic processing of the mask order.

MAX_MASKS_IN_PACKAGE

Integer maximum number of masks to be shipped inside PACKAGE.

MEASURE_FILE_NAME

Alphanumeric name of file to be used for registration mark locations. When MEASURE_FILE_NAME follows MASK_REGISTR_MARK or CELL_REGISTR_MARK, the mark locates the origin of the measure file.

MEASURE_FILE_FORMAT

(MF2, MF3, MTX, IMP, and others on request.)

MEASURED_CD

The critical dimension measurement at the MASK_CD_LOCATION, as measured by the vendor.

MEASURED_CD_TOLERANCE

CD_TOLERANCE of the mask as measured by the vendor.

MEASURED_CD_XY_TOLERANCE

CD_XY_TOLERANCE of the mask as measured by the vendor.

MEASURED_CD_XY_DEVIATION

CD_XY_DEVIATION of the mask as measured by the vendor.

MEASURED_CD_RANGE

CD_RANGE of the mask as measured by the vendor.

MEASURED_CD_THREE_SIGMA

CD_THREE_SIGMA of the mask as measured by the vendor.

MEASURED_CD_DEVIATION_FROM_TARGET

CD_DEVIATION_FROM_TARGET of the mask as measured by the vendor.

MEASURED_CD_DEVIATION_FROM_MEAN

CD_DEVIATION_FROM_MEAN of the mask as measured by the vendor.

MEASURED_ CD_SITE_ID

Must match CD_SITE_ID in <mask_order> for site being measured. If the customer assigned no CD_SITE_ID for the required location (e.g., only CD_LOCATION_DRAWING was used), the vendor will assign a MEASURED_ CD_SITE_ID for each measurement location so that it is unique within the MASK_SET_ID. If REGISTR_MARK_ID was used as a <pattern_options> in <mask_order> for a pattern with multiple instances, then the vendor will add a suffix to CD_SITE_ID for each instance so that each MEASURED_ CD_SITE_ID in <mask_data> will be unique.

MEASURED_CENTRALITY

CENTRALITY as measured by the vendor.

MEASURED_DEFECT_DENSITY

DEFECT_DENSITY as measured by the vendor.

MEASURED_DEFECT_COUNT

DEFECT_COUNT as measured by the vendor.

MEASURED_DEFECT_COUNT_REP

DEFECT_COUNT_REP as measured by the vendor.

MEASURED_DEFECTIVE_DIE_DENSITY

DEFECTIVE_DIE_DENSITY as measured by the vendor.

MEASURED_DEFECTIVE_DIE_COUNT

DEFECTIVE_DIE_COUNT as measured by the vendor.

MEASURED_DEFECTIVE_DIE_COUNT_REP

DEFECTIVE_DIE_COUNT_REP as measured by the vendor.

MEASURED_PERCENT_DEFECTIVE_DIE

PERCENT_DEFECTIVE_DIE as measured by the vendor.

MEASURED_PERCENT_CLEAR

PERCENT_CLEAR as computed by the vendor.

MEASURED_REGISTR_ERROR

REGISTR_ERROR as measured by the vendor.

MEASURED_REGISTR_SCALE

REGISTR_SCALE as measured by the vendor.

MEASURED_REGISTR_RESIDUAL

REGISTR_RESIDUAL as measured by the vendor.

MEASURED_REGISTR_RESIDUAL_THREE_SIGMA

REGISTR_RESIDUAL_THREE_SIGMA as measured by the vendor.

MEASURED_REGISTR_ORTHO

REGISTR_ORTHO as measured by the vendor.

MEASURED_REGISTR_RELATIVE

REGISTR_RELATIVE as measured by the vendor.

MEASURED_MULTIWRITE_OVERLAY_ERROR

MULTIWRITE_OVERLAY_ERROR as measured by the vendor.

MEASURED_ REGISTR _MARK_ID

Must match REGISTR_MARK_ID in <mask_order> for site being measured. If the customer assigned no REGISTR_MARK_ID for the required location (e.g., only MEASURE_FILE_NAME was used), the vendor will assign a MEASURED_REGISTR_MARK_ID for each measurement location so that it is unique within the MASK_SET_ID. If REGISTR_MARK_ID was used as a <pattern_options> in <mask_order> for a pattern with multiple instances, then the vendor will add a suffix to REGISTR_MARK _ID for each instance so that each MEASURED_ REGISTR_MARK_ID in <mask_data> will be unique.

MFG_EQUIP

(EBEAM, OPTICAL, LASER) Acceptable equipment for writing product mask(s).

MFG_MODEL

Model of acceptable mask writing equipment, including (MEBES III, MEBES IV, MEBES_4000, MEBES_4500, MEBES_5000, ZBA_31, ZBA_320, ZBA_340, CORE_2000, CORE_2100, CORE_2500, CORE_2564, ALTA_3000, ALTA_3500, ALTA_3700, TRE_220, ULTRABEAM_V2000, MANN_3000, MANN_3600, HL_800, HL_900, JBX_7000, JBX_9000 and others on request).

MFG_SITE

Alphanumeric identification of qualified manufacturing sites.

MILESTONE

(ORDER_RECEIVED, ORDER_ACCEPTED, DATA_PREPARED, MASK_WRITTEN, CDS_MEASURED, REGISTR_MEASURED, DEFECTS_REPAIRED, PELLICLES_APPLIED, POST_PELLICLE_INSPECTION, SHIPPED, DELIVERED, ON_HOLD, OFF_HOLD) notifies the customer that the MASK_ID has passed the indicated processing step, or is on hold.

MILESTONES

(T or F) If T, the vendor is requested to use <mask_order> (see Section 7.5) to notify the customer each time the mask completes a significant processing step. Within this standard, these significant steps are limited to those defined under MILESTONE. MILESTONES may not be used in combination with PERIODIC_UPDATES for the same MASK_ID.

MIN_MASK_FEATURE_SIZE

Smallest (scaled) feature included in any customer-supplied pattern data on the mask.

MINIMUM_FEATURE_LOCATION

Location of a minimally sized feature within the pattern file, relative to the center of the pattern, unscaled and unmirrored.

MINIMUM_FEATURE_SIZE

Smallest (unscaled) feature included in pattern data, excluding OPC data which is identified under OPC_MINIMUM_FEATURE_SIZE.

MINUS

(x,y,z) Name of file (x) to be formed by logically removing from file (y) the portions of all digitized geometry which overlap with digitized geometry in file (z). The extents of file (x) are the same as the extents of file (y).

MIRROR

(x,y) Name of file (x) to be formed by mirroring the file (y) about its vertical centerline.

MIRROR_MASK

(T or F) All patterns and titles must be mirrored about the vertical axis, to be applied in addition to all other positioning information.

MIRROR_PATTERN

(T or F) If T, the pattern file (or cell) is to be mirrored about its vertical axis. If used in conjunction with MIRROR_MASK, the result will be unmirrored pattern data while all other data will be mirrored.

MIRROR_TITLE

(T or F) If T, TITLE_TEXT is to be mirrored about the vertical axis. If used in conjunction with

MIRROR_MASK, result will be an unmirrored title with all other data mirrored (chrome side up).

MULTIWRITE

(x,y) If present as a mask option, then the MASK_ID represents only one writing operation for a mask which requires multiple write and process cycles (defined within the <mask_group>) before the final mask is completed. All MASK_IDs used to make the final mask must have MULTIWRITE as a <mask_option> and must designate the same integer group number (x). Such a final mask will be built with a specified integer sequence (y) of MASK_IDs. Sequence numbers may never be less than 1 nor more than the number of write and process cycles specified in the order, except that zero may be used where the sequence is arbitrary. A sequence number within a group may not be repeated (except zero).

MULTIWRITE_OVERLAY_ERROR

Maximum allowable overlay error relative to the MULTIWRITE_REF_MASK_ID.

MULTIWRITE_REF_MASK_ID

Within the MULTIWRITE numerical group, this is the MASK_ID to which overlay error should be measured.

NOT

(x,y) Name of file (x) to be formed by the logical inversion of file (y). The resulting file is unbounded (i.e., has no extent limits).

NUMBER_OF_CDS

The integer number of CD locations to be measured. If sufficient specific sites are not explicitly identified by the customer, the vendor is free to select additional similar sites.

OPC_MINIMUM_FEATURE_SIZE

For the OPC_TYPE being described, the size of the smallest OPC feature in the pattern data.

OPC_MINIMUM_GAP

For the OPC_TYPE being described, the size of the smallest gap in the pattern data between OPC features of the same type.

OPC_PATTERN_MODIFIABLE

(T or F) If F, the pattern may not be modified (biased) by the mask shop for printability or CD linearity improvement. In this case, the need for such biasing must have been anticipated by the customer.

OPC_PATTERN_SEPARATE

(T or F) If T, then the pattern being described is only the OPC portion of what will be written on the mask. Depending upon the write tool methodology, the pattern may need to be merged off-line with other patterns. This may allow mask shop biasing for printability or CD linearity unless precluded by OPC_PATTERN_MODIFIABLE = F.

OPC_TYPE

(CLEAR_SERIF, CLEAR_HAMMERHEAD, CLEAR_ASSIST_BAR, OPAQUE_SERIF, OPAQUE_HAMMERHEAD, OPAQUE_ASSIST_BAR) (Linewidth biasing is not included as an OPC type.)

OPERATOR_NAME

Alphabetic name of the person entering the mask order.

OPTICAL_MASK_SET_ID

For optical stepping or contact printing, the “pattern” is to be obtained by using a reticle or mask from this MASK_SET_ID.

OPTICAL_MASK_ID

For optical stepping or contact printing, the “pattern” is to be obtained by using a reticle or mask built under this MASK_ID from the above-named MASK_SET_ID.

OPTICAL_MASK_TITLE

For optical stepping or contact printing, identifying title on reticle or mask. To be used in place of OPTICAL_MASK_SET_ID and OPTICAL_-MASK_ID when the reticle or mask was built without available <mask_order> data.

OR

(x,y,z) Name of file (x) to be formed by the logical union of file (y) and file (z). The extents of the pattern file (x) are described by the smallest rectangle which encloses both file (y) and file (z).

ORDER_ACCEPTED

Returns the exact FILE_DATE_TIME as in the file being accepted, thereby agreeing to process the order as received.

ORDER_RECEIVED

Returns the exact FILE_DATE_TIME as in the file being acknowledged, thereby confirming receipt of that file. This response is required each time a new transmission is received by the vendor.

ORDER_ID

Printable text of the customer's internal order identification to provide correlation with pre-existing order tracking systems. This is for customer cross-referencing only and will be ignored in automatic processing.

PACKAGE

Alphanumeric identification of brand and model of acceptable compact to be used for delivering masks.

PATTERN_ADDRESS_SIZE

Address unit of the (unscaled) pattern file. If this is incorrect, the mask will not be written until it is corrected. For data manipulation operations, this is the address to use in final fracturing to produce a pattern file for exposure.

PATTERN_CD_LOCATION

(x,y) Location of critical dimension feature within a pattern file or cell, relative to the center of the pattern, before mirroring or scaling.

PATTERN_CHARACTER_SET

(ASCII or EBCDID) ASCII is assumed unless otherwise specified.

PATTERN_FORMAT

(MEBES_I, MEBES_II, MEBES_EXTENDED, MEBES_RETICLE, MEBES_V, EEBES, HITACHI_700, HITACHI_800, JEOL_51, JEOL_52, ULTRABEAM, ZBA, ALF, MANN_3000, MANN_3600, ELECTROMASK, GDS-II, CIF, APPLICON, CATS_CFLT, CATS_CREF, AUTOCAD, KLARIS, FALCON, ORBOT and others on request) Format of preceding pattern file. For <data_manipulation> operations, this is the format to use for the output file resulting from the operation.

PATTERN_GROUP_ID

Name of the pattern group which follows; must be used in all references within this MASK_SET_ID to this pattern group.

PATTERN_GROUP_INSTANCE

Identifies PATTERN_GROUP_ID to be placed by the following location information.

PATTERN_NAME

Printable ASCII pattern file name. The file may be received intact, or may be derived through data manipulation.

PATTERN_PLOT_APPR_REQD

(T or F) If T, customer approval of the pattern plot is required before mask making is authorized.

PATTERN_PLOT_NORMAL_TONE

(T or F) If T, digitized data will be dark.

PATTERN_PLOT_SCALE

Numeric scale of the pattern plot.

PATTERN_UNITS

(METRIC, ENGLISH) Units of preceding pattern file.

PATTERN_VISUAL_ID

Optional, printable text to specify identification within the pattern file which must be visually confirmed as present before the mask may be written. If the feature is not present, the mask order should go on hold.

[PERCENT_CLEAR]

Percentage of the patterned area which will become transparent after the mask is processed. As a mask option it includes all the area within the scribe pattern limits. As a pattern option it includes the area within the individual pattern limits.

[PERCENT_CLEAR_REQUESTED]

(T or F) If T, the vendor is requested to calculate, using available CAD tools, the percentage of the patterned area on the mask which will become transparent after the mask is processed, and transmit this value to the customer.

PERCENT_DEFECTIVE_DIE

Maximum percentage of defective die among those required by the customer to meet defect criteria.

PERIODIC_UPDATE

notifies the customer that MASK_ID has passed the indicated processing step, or is on hold.

PERIODIC_UPDATES

(integer) If non-zero, the vendor is requested to use <mask_order> (see Section 7.5) to notify the customer on a periodic basis which significant processing step was last completed for MASK_ID. The value of the data field indicates the number of hours between updates. Within this standard, these significant steps are limited to those defined under MILESTONE. PERIODIC_UPDATES may not be used in combination with MILESTONES for the same MASK_ID.

PHASE_ANGLE_ERROR

Maximum acceptable deviation (in degrees) of any phase shift measurement from the PHASE_ANGLE_TARGET.

PHASE_ANGLE_RANGE

Maximum acceptable variation (in degrees) of phase shift measurements, relative to each other.

PHASE_ANGLE_TARGET

The required phase shift in degrees at the specified WAVELENGTH.

PHASE_ANGLE_TOLERANCE

The maximum acceptable deviation of the mean of all phase shift measurements (in degrees) to the PHASE_ANGLE_TARGET.

PLACEMENT_TOP_CELL

Name of CELL_ID which defines all pattern placements for this MASK_GROUP_ID. This referenced cell is centered on the mask.

PO_NUMBER

Alphanumeric purchase order number.

PRICE

Price (excluding freight and taxes) for preceding item (e.g., mask, pellicle, plot, database inspection).

PRICE_UNITS

(DOLLAR, POUND, SFRANC, FFRANC, GUILDER, LIRE, YEN) Monetary unit used in all references to PRICE with the <mask_set>.

PROCESS

Alphanumeric name of the special process to be used in making the masks.

PRODUCT_AS_CHECKPLATE

(T or F) If T, product mask is to be used for check-plate approval prior to making other product masks.

PRODUCT_IMAGING_TYPE

(BINARY, AAPSM, EAPSM, COMPLIMENTARY or BINARY_TRIM)

PRODUCT_MAGNIFICATION

(10X, 5X, 4X, 2.5X, 2X, 1X) Factor by which the exposure tool will reduce the image on the photomask (reticle) to form the image on the wafer.

PRODUCT_TYPE

(1X_FULL_FIELD, 1X_STD_FIELD_RETICLE, 1X_WIDE_FIELD_RETICLE, RETICLE, CONTACT, SUBMASTER, CHECKPLATE, PROBE_PLATE, REPELLICLIZE and REINSPECT)

QUALITY_GROUP_ID

Alphanumeric customer's label for a collection of mask quality specifications, to be used only in addition to explicit quality requirement keywords. This may not be used in the data structure in place of quality requirement keywords.

QUANTITY

Integer number of array plots, pattern plots and films. May also apply to masks only when PRODUCT_TYPE is contact masks.

QUOTE_NUMBER

Vendor's quotation number to be referenced in billing documents.

REGISTR_ALGORITHM

(ONE-POINT, TWO-POINT or MULTI-POINT, x1,y1,x2,y2) Specifies the method for analyzing registration reference marks. For ONE-POINT analysis, (x1,y1) is the fixed point and (x2,y2) is used for angular orientation only. For TWO-POINT analysis, (x1,y1) and (x2,y2) are both used for angular orientation and the fixed reference point is midway between the two. If MULTI-POINT, (x1, y1, x2, y2) is omitted. MULTI-POINT is the fit of all measured points resulting in zero mean error in x and zero mean error in y.

REGISTR_CLOSURE

Maximum positional error between patterns written at the beginning of writing the mask and the end of writing the mask.

REGISTR_CLOSURE_BEGIN

Identifies the CELL_ID or PATTERN_GROUP_ID to be used at the beginning of writing the mask for REGISTR_CLOSURE measurement.

REGISTR_CLOSURE_END

Identifies the CELL_ID or PATTERN_GROUP_ID to be used at the end of writing the mask for REGISTR_CLOSURE measurement.

REGISTR_EQUIP_REQD

Alphanumeric identification of acceptable equip-ment for measuring REGISTR_ERROR and REGISTR_ORTHO.

REGISTR_ERROR

Maximum allowable registration error, relative to the REGISTR_REF_MASK_ID or the reference grid of REGISTR_EQUIP_REQD.

REGISTR_MARK_COUNT

(x,y) For a rectangular array of registration marks, the number of rows (x) and columns (y).

REGISTR_MARK_ID

Unique alphanumeric identifier of each registration mark location within MASK_SET_ID to identify individual registration measurements when using <mask_data>. If the same coordinates apply to locations on different masks within the mask set, they may have the same REGISTR_MARK_ID, but it is not mandatory. If REGISTR_MARK_ID is used with a CELL_REGISTRATION_MARK, it will be associated with as many mask locations as the cell has instances. (See MEASURED_REGISTR_MARK_ID for more information.)

REGISTR_MARK_SEPARATION

(x, y) For an array of registration marks, the spacing between successive marks in the horizontal (x) and vertical (y) directions.

REGISTR_ORTHO

Maximum allowable non-orthogonality, in micro-radians, relative to the REGISTR_REF_MASK_ID or the reference grid of REGISTR_EQUIP_REQD.

REGISTR_REF_MASK_ID

MASK_ID of the reference mask for determining REGISTR_ERROR and REGISTR_ORTHO. If multiple masks are identified, the reference grid should be based on the mean of the measurements of the group of masks.

REGISTR_REF_MASK_NAME

To be used in place of REGISTR_REF_MASK_ID only to refer to those mask sets which were built outside the SEMI order standard and have no MASK_ID.

REGISTR_REF_MASK_SET_ID

MASK_SET_ID for the mask set containing REGISTR_REF_MASK_ID for determining REGISTR_ERROR and REGISTR_ORTHO.

REGISTR_REF_MASK_SET_NAME

To be used in place of REGISTR_-REF_MASK_SET_ID only to refer to those mask sets which were built outside the SEMI order standard and have no MASK_SET_ID.

REGISTR_REF_MASK_SET_VERSION

To be used in addition to REGISTR_-REF_MASK_SET_NAME only to refer to those mask sets which were built outside the SEMI order standard and have no MASK_SET_ID.

REGISTR_REF_METHOD

Alphanumeric description of the method and/or reference marks to use for measuring REGISTR_-ERROR and REGISTR_ORTHO (e.g., using a previously established reference, or the REGISTR_-EQUIP_REQD grid).

REGISTR_RELATIVE

If present, indicates that the START_REGISTR collection in which REGISTR_RELATIVE is contained is to be measured relative to another START_REGISTR collection, rather than to the grid of the registration measurement tool. The alphanumeric data field of REGISTR_RELATIVE must match the data field of START_REGISTR of the collection to which it is to be compared.

REGISTR_RESIDUAL (x,y)

The maximum acceptable deviation in each axis (in microns) of all registration measurements relative to the REGISTR_STD_GRID, with REGISTR_SCALE and REGISTR_ORTHO removed.

REGISTR_RESIDUAL_THREE_SIGMA (x,y)

The maximum acceptable 3 sigma deviation in each axis (in microns) of all registration measurements, with REGISTR_SCALE and REGISTR_ORTHO removed.

REGISTR_SCALE (x,y)

Maximum acceptable scale error in each axis in parts per million, relative to the REGISTR_STD_GRID.

REGISTR_STD_GRID

(NIST, PTB and others on request) reference standard to be used to correlate registration measurement. This keyword is not allowed in conjunction with REGISTR_REF_METHOD on the same mask.

RELEASE_NUMBER

Alphanumeric release number under BLANKET PO NUMBER.

REPAIRS_AUTHORIZED

(T or F) If F, customer approval is required before mask repairs can be made.

RESIST_TYPE

(POSITIVE or NEGATIVE) This data item is needed for <mask_order> only if overlapping patterns are required. (Overlapping patterns sometimes require the use of “blanking rectangles” to prevent exposure of areas which are to be exposed by another pattern.)

RETROFIT_JOB_LEVEL

Level in RETROFIT_JOB_NAME to which new mask(s) must retrofit.

RETROFIT_JOB_NAME

Name of job file to which mask(s) must retrofit.

RETROFIT_MASK_ID

MASK_ID in RETROFIT_MASK_SET_ID to which new mask(s) must retrofit.

RETROFIT_MASK_NAME

To be used in place of RETROFIT_MASK_ID only for retrofit to those mask sets which were built outside the SEMI order standard and have no MASK_SET_ID.

RETROFIT_MASK_SET_ID

MASK_SET_ID of mask set to which new mask(s) must retrofit.

RETROFIT_MASK_SET_NAME

To be used in place of RETROFIT_MASK_SET_ID only for retrofit to those mask sets which were built outside the SEMI order standard and have no MASK_SET_ID.

RETROFIT_MASK_SET_VERSION

To be used in addition to RETROFIT_-MASK_SET_NAME only for retrofit to those mask sets which were built outside the order standard and have no MASK_SET_ID.

REVIEW_REQD

If present, indicates that a review will be required but that it need not be completed prior to building and/or shipping the masks. The alphanumeric data field describes the items to be reviewed.

ROTATE_TITLE

(0, 90, 180 or 270) Title is to be rotated clockwise the indicated number of degrees, prior to any mirroring.

ROTATE_TITLE_CHARACTERS

(0, 90, 180 or 270) Characters within the title are to be rotated clockwise the indicated number of degrees, prior to any mirroring.

ROTATION

(x,y,z) Name of file (x) to be formed by rotating the file (y) counter-clockwise about its center by (z) in degrees. Allowable values for (z) are 0, 90, 180 or 270.

SCALE_FACTOR

(De)magnification factor to be multiplied with the PATTERN_ADDRESS_SIZE to get the effective address to be used to write the pattern file. Data value must be positive. 1.0 is assumed unless specified otherwise. SCALE_FACTOR alters both the size of individual geometries and the size of the pattern file.

SCRATCH_SIZE_BACK

Maximum dimension of smallest unacceptable scratch on glass side of mask.

SCRATCH_SIZE_FRONT

Maximum dimension of smallest unacceptable scratch on patterned side of mask.

SCRIBE_INSIDE_CORNERS

(X1,Y1,X2,Y2) The inner limits of the SCRIBE_-TONE frame to be built for the dropout by the vendor. It consists of two pairs of coordinates: the lower-left and upper-right.

SCRIBE_OUTSIDE_CORNERS

(X1,Y1,X2,Y2) The outer limits of the SCRIBE_-TONE frame to be built for the dropout by the vendor. It consists of two pairs of coordinates: the lower-left and upper-right.

SCRIBE_TONE

(CLEAR or DARK) Border surrounding DROP-OUT on mask is to be either clear or dark.

SECURITY_CLASS

(QML, SECRET, TOP_SECRET, CCI, or COMSEC) Security classification of mask set or individual mask.

SEMI_REVISION

Revision identification of the SEMI standard according to which the <mask_order> data structure was constructed. This revision is P10-0301.

SERIAL_NUMBER

(T or F) If T, a mask serial number must be included on the mask.

SHIP_ARRAY_PLOT

If present, array map must be sent to customer. Indicates beginning of <array_plot> collection. Alphanumeric data field identifies the collection to establish which collections are hierarchically affected by another. The appearance of a <array_plot> at a lower level in the hierarchy supercedes the <array_plot> at a higher level in the hierarchy if it has the same SHIP_ARRAY_PLOT data field.

SHIP_ARRAY_REGISTR_MAP

(T or F) If T, requires delivery of the registration map of the entire array to the customer.

SHIP_BARCODE_PLOT

(T or F) If T, the plot of the barcode must be sent to the customer.

SHIP_CD_DATA

(T or F) If T, requires delivery of all critical dimension measurements, criteria and evaluation data to the customer for all cd criteria specified.

SHIP_CD_PRINTOUT

(T or F) If T, requires delivery to the customer of the printout from the cd measurement tool.

SHIP_CD_UNIFORMITY_MAP

(T or F) If T, requires delivery to the customer of the uniformity map from the cd uniformity measurement tool.

SHIP_CENTRALITY_DATA

(T or F) If T, requires delivery of the centrality measurement to the customer.

SHIP_CENTRALITY_MAP

(T or F) If T, requires delivery of the centrality map to the customer.

SHIP_CERTIFICATE_OF_CONFORMANCE

(T or F) If T, requires delivery of a certificate of conformance to the customer.

SHIP_CUSTOMER_QUALITY_FORM

(text) If present, the data field specifies the form required by the customer to document the quality of the mask.

SHIP_DEFECT_DATA

(T or F) If T, requires delivery of defect inspection criteria and evaluation data to the customer for all defect criteria specified. This should be final inspection data unless SHIP_THRU_PELLICLE_DATA is specified, in which case it should be for final inspection prior to pelliclizing.

SHIP_DIE_FIT_MAP

(T or F) If T, requires delivery of a die fit map to the customer.

SHIP_FILM

If present, film(s) of mask(s) must be sent to customer. Indicates beginning of <films> collection. Alphanumeric data field identifies the collection to establish which collections are hierarchically affected by another. The appearance of a <films> at a lower level in the hierarchy supercedes the <films> at a higher level in the hierarchy if it has the same SHIP_FILM data field.

SHIP_FIELD_FIT_MAP

(T or F) If T, requires delivery of a field fit map to the customer.

SHIP_FINAL_POSTPELL_DIE_DB_MSK_MAP

(T or F) If T, requires delivery of the final run, post-pellicle die to database defect inspection map for the entire patterned area to be sent to customer.

SHIP_FINAL_POSTPELL_DIE_DB_PTN_MAP

(T or F) If T, requires delivery of the final run, post-pellicle die to database defect inspection map for the single pattern to be sent to customer.

SHIP_FINAL _POSTPELL_DIE_DIE_MAP

(T or F) If T, requires delivery of the final run, post-pellicle die to die defect inspection map for the entire mask to be sent to customer.

SHIP_FINAL_PREPELL_DIE_DB_MSK_MAP

(T or F) If T, requires delivery of the final run, pre-pellicle die to database defect inspection map for the entire patterned area to be sent to customer.

SHIP_FINAL_PREPELL_DIE_DB_PTN_MAP

(T or F) If T, requires delivery of the final run, pre-pellicle die to database defect inspection map for the single pattern to be sent to customer.

SHIP_FINAL _PREPELL_DIE_DIE_MAP

(T or F) If T, requires delivery of the final run, pre-pellicle die to die defect inspection map for the entire mask to be sent to customer.

SHIP_FINAL_ROT_POSTPELL_DIE_DIE_MAP

(T or F) If T, requires delivery of the final run, post-pellicle rotated die to die defect inspection map for the entire mask to be sent to customer.

SHIP_FINAL_ROT_PREPELL_DIE_DIE_MAP

(T or F) If T, requires delivery of the final run, pre-pellicle rotated die to die defect inspection map for the entire mask to be sent to customer.

SHIP_FIRST_POSTPELL_DIE_DB_MSK_MAP

(T or F) If T, requires delivery of the first run, post-pellicle die to database defect inspection map for the entire patterned area to be sent to customer.

SHIP_FIRST_POSTPELL_DIE_DB_PTN_MAP

(T or F) If T, requires delivery of the first run, post-pellicle die to database defect inspection map for the single pattern to be sent to customer.

SHIP_FIRST_POSTPELL_DIE_DIE_MAP

(T or F) If T, requires delivery of the first run, post-pellicle die to die defect inspection map for the entire mask to be sent to customer.

SHIP_FIRST_PREPELL_DIE_DB_MSK_MAP

(T or F) If T, requires delivery of the first run, pre-pellicle die to database defect inspection map for the entire patterned area to be sent to customer.

SHIP_FIRST_PREPELL_DIE_DB_PTN_MAP

(T or F) If T, requires delivery of the first run, pre-pellicle die to database defect inspection map for the single pattern to be sent to customer.

SHIP_FIRST_PREPELL_DIE_DIE_MAP

(T or F) If T, requires delivery of the first run, pre-pellicle die to die defect inspection map for the entire mask to be sent to customer.

SHIP_FIRST_ROT_POSTPELL_DIE_DIE_MAP

(T or F) If T, requires delivery of the first run, post-pellicle rotated die to die defect inspection map for the entire mask to be sent to customer.

SHIP_FIRST_ROT_PREPELL_DIE_DIE_MAP

(T or F) If T, requires delivery of the first run, pre-pellicle rotated die to die defect inspection map for the entire mask to be sent to customer.

SHIP_INSP_DATABASE_DATA

(T or F) If T, requires delivery of die-to-database inspection data to the customer.

SHIP_JOB_DATA_PLOT

(T or F) If T, requires delivering to the customer a plot of the entire patterned area of the mask, including the image of the pattern file data.

SHIP_MEASURE_FILE_REGISTR_MAP

(T or F) If T, requires delivering to the customer the measure file registration map.

SHIP_PATTERN_PLACEMENT_MAP

(T or F) If T, requires delivering to the customer a plot of the entire patterned area of the mask,, showing only an outline of each individual pattern file.

SHIP_PATTERN_PLOT

(T or F) If T, the pattern plot must be sent to customer.

SHIP_PHASE_SHIFT_REPORT

(T or F) If T, requires delivering to the customer a report of the phase shift characteristics of the mask.

SHIP_MANUAL_INSPECTION_FORM

(T or F) If T, requires delivering to the customer a copy of the manual inspection form.

SHIP_REGISTR_DATA

(T or F) If T, requires delivery of all registration measurements, criteria and evaluation data to the customer for all registration criteria specified.

SHIP_REPAIR_DATA

(T or F) If T, requires delivery of repair data to the customer.

SHIP_SEM_PHOTOS

(T or F) If T, requires delivery of SEM photos to the customer.

SHIP_SPECIAL_REQUEST

(text) If present, the data field specifies the special request of the customer.

SHIP_STARLIGHT_MAP

(T or F) If T, requires delivery of a defect map from the Starlight to the customer.

SHIP_ SURF_INSP_GLASS_SIDE_MAP

(T or F) If T, the final, post-pellicle, surface inspection map of the glass side of the mask must be sent to the customer.

SHIP_ SURF_INSP_PATTERN_SIDE _MAP

(T or F) If T, the final, post-pellicle, surface inspection map of the patterned side of the mask must be sent to the customer.

SHIP_ SURF_INSP_PELL_TOP_MAP

(T or F) If T, the final, post-pellicle, surface inspection map of the pellicle on the patterned side of the mask must be sent to the customer.

SHIP_SURF_INSP_PELL_BOTTOM_MAP

(T or F) If T, the final, post-pellicle, surface inspection map of the pellicle on the glass side of the mask must be sent to the customer.

SHIP_SURF_INSPECTION_MAP

(T or F) If T, the final, post-pellicle, surface inspection map(s) must be sent to the customer.

SHIP_THRU_PELLICLE_DATA

(T or F) If T, requires delivery of through-pellicle defect inspection criteria and evaluation data to the customer for all defect criteria specified. This should be final inspection data.

SHIP_TRAVELER

(T or F) If T, requires delivery of mask traveler document to the customer.

SHIPPING_ADDRESS

Address for delivery of masks.

SHIPPING_CONTACT

Name of person to receive masks.

SHIPPING_EMAIL

Internet address for SHIPPING_CONTACT.

SHIPPING_FAX

Phone number for facsimile machine of SHIPPING_CONTACT.

SHIPPING_PHONE

Phone number for SHIPPING_CONTRACT.

SHIPPING_METHOD

Transportation method for masks, including special arrangements for off-hours and weekends.

SIZING

(x,y,z) Name of file (x) to be formed by (de)increasing the width and height of all geometry within the file (y) by (z) in microns. Note that (z) results in a “one-sided” (de)increase in feature size.

SIZING_RULE

(SQUARE, PARAGON, EXTEND, OCTAGON and others on request) Describes methodology for applying SIZING around corners.

SIZING_BORDER_RULE

(FIT, INSIDE, OUTSIDE and others on request) Describes methodology for applying SIZING at the borders of the output file and the effect on the final dimensions of the output file.

SO_NUMBER

Alphanumeric sales order number.

START_BARCODE

(text) name of barcode.

START_CD

Indicates beginning of <cd_definition>. Defines separation between multiple <cd_definition>s. Alphanumeric data field identifies the collection to establish which collections are hierarchically affected by another. The appearance of a <cd definition> at a lower level in the hierarchy supercedes the *entire* <cd definition> at a higher level in the hierarchy *if and only if* it has the same START_CD data field.

START_CD_MEASUREMENTS

(text) name of cd measurement group.

START_DATA_MANIPULATION

(text) name of group of data manipulation commands.

START_DEFECT_DEFINITION

(text) name of <defect_definition> group.

START_DEFECT_MEASUREMENTS

(text) name of <defect_measurements> group.

START_MASK_DATA

Indicates the beginning of the file from the vendor to the customer containing actual mask data. Should match the data field of the START_ORDER to which it is responding AND the data field of END_MASK_DATA.

START_OPC

(text) name of <opc_definition> group.

START_ORDER

Indicates the beginning of order entry data file from the customer to the vendor. Should indicate the name(s) of the mask sets included.

START_PATTERN_OPTIONS

(text) name of <pattern_options> group.

START_PHASESHIFT

(text) name of <phase_shift> group.

START_PLACEMENT

(text) name of <placement> group.

START_REGISTR

Indicates beginning of <registration> collection. Defines separation between multiple <registra-tion>s. Alphanumeric data field identifies the collection to establish which collections are hierarchically superceded by another; also for reference by REGISTR_RELATIVE.

START_REGISTR_MEASUREMENTS

(text) name of <registration_measurements> group.

START_SHIP_TO

(text) name of <ship_to> group.

START_SHIPPABLE_DATA

(text) name of <shippable_data> group.

START_TITLE

(title number) Indicates the beginning keywords for a specific title.

STATUS

(NEW, OLD, CHANGE, CANCEL, STOP, RESTART, RETURNED, PROTESTED) Present status of mask(s); NEW = new mask which has not been ordered before. OLD = previously ordered mask whose data is included for reference only. CHANGE = previously ordered mask whose data is included because the order data has been changed since the last transmission. CANCEL = previously ordered mask whose order is being cancelled. STOP = previously ordered mask which is put on hold until further notice. RESTART = changes a previous STATUS of STOP from being on hold to being released for production. RETURNED = a previously delivered mask which has been rejected by the customer and is being returned to the vendor. A data entry transmittal which includes a RETURNED mask should also include a NEW mask if replacement is to be initiated. PRICE of the returned mask should be the negative of the original price in order to track credit. The NEW mask should also contain PRICE and a new schedule. PROTESTED = a RETURNED mask whose rejection is protested by the mask vendor. If a NEW mask accompanied the RETURNED mask to initiate replacement, the NEW mask should also have PROTESTED status.

START_VENDOR_INFO

(text) name of <vendor_info> group.

STD_PATTERN_NAME

Name of a standard pattern, on file at the vendor, previously supplied or authorized by the customer.

STEPPING_COUNT

(x,y) Count of successive pattern or cell placements.

STEPPING_DISTANCE

(x,y) Spacing between successive pattern or cell placements.

STRIPE_HEIGHT

Stripe height in address units of pattern file.

SURF_INSP_AREA

(x1,y1,x2,y2) Unscaled coordinates of window for surface inspection, lower left and upper right corners, relative to center of mask, pattern or cell (chrome side up for masks, unmirrored for patterns or cells).

SURF_INSP_GLASS_SIDE

If present, specifies the maximum dimension of the smallest unacceptable particle on the glass side of the mask.

SURF_INSP_METHOD

(LASER, VISUAL, PIXEL or MICROSCOPE) Methodology for detecting surface particles.

SURF_INSP_PATTERN_SIDE

If present, specifies the maximum dimension of the smallest unacceptable particle on the patterned side of the mask.

SURF_INSP_PELL_BOTTOM

If present, specifies the maximum dimension of the smallest unacceptable particle on the pellicle on the glass side of the mask.

SURF_INSP_PELL_TOP

If present, specifies the maximum dimension of the smallest unacceptable particle on the pellicle on the patterned side of the mask.

SURFACE_INSPECTION

If present, requires surface inspection and specifies the maximum dimension of the smallest unacceptable surface particles.

SURROUNDING_HEIGHT

Height of clear or dark border around pattern on mask.

SURROUNDING_TONE

(CLEAR or DARK) Border surrounding pattern on mask is to be either clear or dark.

SURROUNDING_WIDTH

Width of clear or dark border around pattern on mask.

THROUGH_PELLICLE_DEFECTS

Precedes <defect_measurements> when delivering defect data measured with pellicle applied.

TITLE_HEIGHT

(height) Height in microns of title characters.

TITLE_JUSTIFICATION

(L or R) Left or right justification within the writable field, before mirroring and before rotation.

TITLE_LOCATION

(x,y) Location of the lower left corner of the above-specified TITLE_TEXT (before mirroring or rotation).

TITLE_TEXT

(text) Alphanumeric contents of human-readable text to be written on mask.

TITLE_TYPE

(MASK, DEVICE, DATE_TIME, SOFTWARE, SERIAL_NUMBER, AUXILIARY)

TITLES

(text) TITLE_TEXT of title on the mask. This keyword should be repeated until each title appearing on the mask is listed.

TOP_PELLICLE_TYPE

Alphanumeric brand and model of acceptable pelli-cle for the patterned side of the mask. If multiple pellicles are listed, they are prioritized with the most preferred first and least preferred last.

TRANSMISSION_DEFECT_CLEAR

Maximum allowable percent transmission of light through a clear defect.

TRANSMISSION_DEFECT_DARK

Maximum allowable percent blocking of light through a dark defect.

TRANSMISSION_ERROR

For phase shift masks, the maximum acceptable deviation of any percent transmission measurement from the TRANSMISSION_TARGET.

TRANSMISSION_RANGE

For phase shift masks, the maximum acceptable variation of all percent transmission measurements, relative to each other.

TRANSMISSION_TARGET

For phase shift masks, the required percent transmission of light at the specified WAVELENGTH compared to quartz.

TRANSMISSION_TOLERANCE

For phase shift masks, the maximum acceptable deviation of the mean of all percent transmission measurements to the TRANSMISSION_TARGET.

UNSCALED_PATTERN_SIZE

(x,y) Unscaled size of the pattern file. If this is incorrect, the mask will not be written until it is corrected.

USER_UNIT

To be used for fracturing DATABASE_SOURCE into inspection data, as required by some inspection systems.

UT1X_UNCUT

(T or F) If T, indicates that the reticle is to be delivered uncut (i.e., 5 inch square) size. If F, or if the keyword is absent, the reticle is to be delivered in the 3 inch by 5 inch size.

VENDOR

The name of the company from which the masks are ordered.

VENDOR_ADDRESS

Address for VENDOR_CONTACT.

VENDOR_CONTACT

Name of person to contact regarding the mask.

VENDOR_EMAIL

Internet address for VENDOR.

VENDOR_FAX

Phone number for facsimile machine of VENDOR.

VENDOR_PHONE

Phone number for VENDOR_CONTACT.

VISUAL_INSPECTION_OK

(T or F) If T, the area of the preceding pattern may be inspected visually and/or automatically at the vendor's option. VISUAL_INSPECTION_OK is not allowed if either VISUAL_INSPECTION_REQD or AUTO_INSPECTION_REQD is T (true).

VISUAL_INSPECTION_REQD

(T or F) Visual, microscopic inspection of the mask for defects is required.

WAFER_EXPOSURE_TOOL

Alphanumeric brand and model of the stepper or aligner on which the mask is to be used.

WAVELENGTH

Wavelength in nanometers of the stepper or aligner on which the mask is to be used.

XOR

(x,y,z) Name of file (x) to be formed by the logical union of file (y) and file (z), excluding all areas in which they intersect.

9 Computing the Checksum

9.1 The cyclic checksum is computed as follows:

9.1.1 Initialize the 16 bit checksum value to zero. Consider all the records in the data file from START_ORDER through END_ORDER, inclusive. Consider each ASCII character up to and including the "new_line" character. Convert each character to its ASCII numeric equivalent (e.g., space is 32 decimal, "A" is 65 decimal, etc.) Use the value 10 decimal for the new_line function regardless of its internal representation (e.g., CR LF). Use only the 7 bit ASCII representation for each character (i.e., ignore the high order bit in an 8 bit byte).

9.1.2 XOR each of the characters from each of the records in sequence, from the first character in the START_-ORDER record to the new_line character in the END_ORDER record. Before each character is XORed with the checksum, circularly rotate the previous value of the accumulated 16 bit checksum one bit to the left.

9.1.3 After all of the above characters have been accumulated into the checksum, convert it as an unsigned 16 bit integer into the ASCII representation of its decimal value. This ASCII string is the data field following the CHECKSUM keyword, the last record in the mask order structure.

SEMI P11-0997
DETERMINATION OF TOTAL NORMALITY FOR ALKALINE DEVELOPER SOLUTIONS

1 Scope

1.1 An acid-base potentiometric titration to single or multiple inflection points is performed on an automatic recording titrator using standardized hydrochloric acid as the titrant. The normality (meq/mL) is then calculated by the titrator using the data obtained.

2 Apparatus

2.1 Autotitrator

2.2 Glass combination electrode

2.3 Class A grade volumetric pipets in 1 to 25 mL sizes

2.4 250 mL beakers

3 Reagents

3.1 1.0 *N* Hydrochloric acid (from concentrate or ready to use 1.0 *N*)

3.2 *Primary Standard* — High-purity sodium carbonate is available from most chemical supply houses, but must be dried at 400 degree centigrade before use. TMAH (tris (hydroxymethyl) aminomethane) is also available from the National Institute of Standards and Technology (Standard Reference Material 723a) for this purpose.

3.3 Buffer solutions, pH 4.0, 7.0, 10.0.

4 Procedure

4.1 Standardize the 1.0 *N* Hydrochloric acid with the primary standard.

4.2 Standardize the titrator by performing a two point calibration with pH 4.0, 7.0, and 10.0 buffer.

4.3 Pipette an appropriate aliquot (1 to 25 mL) of sample into a 250 mL beaker containing a magnetic stir bar. Sample size should be determined according to the expected normality and the amount of titrant to be dispensed that will give the optimum precision and accuracy. Generally this is between one-half and three-quarters the capacity of the burette. (See the instrument manual for the recommended optimum range.)

4.4 Add deionized water to bring the volume to approximately 150 mL.

4.5 Without delay (to prevent carbon dioxide absorption), begin stirring without a vortex and titrate to beyond the inflection endpoint.

4.6 Determine the exact endpoint and record the volume of titrant consumed at the middle of the inflection endpoint. This will be done automatically on most newer digital titrators. On analog titrators, the inflection point can be determined by using the first derivative mode, or accurately determining the middle of the inflection.

5 Calculation

5.1 Calculate the normality of the sample by the following equation.

$$\text{Normality (N)} = \frac{\text{Volume of titrant (mL)} \times \text{Normality of titrant (N.HCL)}}{\text{Sample Volume (mL)}}$$

SEMI P12-0997

DETERMINATION OF IRON, ZINC, CALCIUM, MAGNESIUM, COPPER, BORON, ALUMINUM, CHROMIUM, MANGANESE, AND NICKEL IN POSITIVE PHOTORESISTS BY INDUCTIVELY COUPLED PLASMA EMISSION SPECTROSCOPY (ICP)

1 Scope

1.1 This procedure is an ICP plasma emission analysis for determination of iron, zinc, calcium, magnesium, copper, boron, aluminum, chromium, manganese, and nickel in photoresist. The applicable concentration range is 0.1 to 1 ppm when the sample is diluted 1 to 4. The precision was found to be within 0.1 ppm in a round robin analysis between four laboratories.

2 Spectrometer

2.1 A grating instrument with resolution sufficient to separate the analytical emission lines in Table 1 is required.

Table 1 Analytical Lines of the Elements

Elements	*Analytical Line, nm*	*Elements*	*Analytical Line, nm*
Aluminum	309.271	Magnesium	285.213
Calcium	317.933	Nickel	231.604
Copper	324.754	Zinc	213.856
Iron	239.562	Chromium	283.563
Boron	208.960	Manganese	257.610

3 Sample Preparation

3.1 The sample is diluted 1/4 (1 part of sample plus 3 parts of solvent weight/weight) in 2-methoxyethanol or another suitable solvent for positive resist. The solvent should contain less than 0.03 ppm of the above elements.

4 Standards

4.1 The standards should be weight/weight (mg/kg) and should be diluted weight/weight since results will be expressed in mg/kg.

4.2 The standards are prepared by diluting a concentrated standard of organic-soluble metals in 2-methoxyethanol or other suitable solvent. For example, a 500 ppm standard is diluted to 50 ppm with xylene. This solution is then diluted to 0.25 ppm with 2-methoxythanol.

5 Plasma Conditions

5.1 The sample is pumped on the region of 0.7 mL/min, usually with a perstaltic pump attached to the nebulizer. Choose a tubing that is not attacked by methyl cellosolve (for example, polytetrafluoro-ethylene). The argon plasma flow rate and RF power should be optimized for the sample using settings recommended in the manufacturer’s manual. Generally, a plasma gas flow rate of 16 1/min. is necessary to ionize organic solutions and an RF power of 1.7 watts is required.

6 Quantitation

6.1 The detector gain is set by measuring the 0.25 ppm standard. The background is measured with the solvent and several sample measures. The standard and blank should be run intermittently to satisfy reasonable precision. Standard and sample readings should be repeatable within 0.03 ppm. The effect of sample viscosity on delivery of diluted resist to the plasma was not found to be a factor for the resist tested for this procedure. This effect can be checked by adding an internal standard of an element known not to be present in the resist (such as Yttrium) at ppm and checking the emission response vs. external 1 ppm Yttrium standard in the diluting solvent.

7 Calculation

7.1 ppm element (mg/kg = ppm measured × delution factor (weight/weight)

7.2 *Detection Limit* — The detection limit is a function of the dilution factor and can vary by instrument. The dilution factor should be taken into account in calculation of detection limit.

7.2.1 Detection limit (ppm) = s × dilution factor where s = standard deviation of instrument readings in ppm.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

SEMI P13-91
DETERMINATION OF SODIUM AND POTASSIUM IN POSITIVE PHOTORESISTS BY ATOMIC ABSORPTION SPECTROSCOPY

1 Scope

This procedure is a flame atomic absorption analytical method for sodium and potassium analysis in photoresist. The applicable concentration range is 0.1 to 1 ppm when the sample is diluted one to four. The precision was found to be within 0.1 ppm in a round-robin analysis between four laboratories.

2 Atomic Absorption Spectrometer

The analytical wavelength for sodium is 589.0 nm and for potassium is 766.0 nm. The instrument conditions (i.e., slit width, burner gas flow rates) should be set according to the manufacturer's manual (the fuel flow should be set to approximately 1/2 the air flow to optimize for organic solvent). Optimize the nebulizer and lamp alignment to maximize the absorbance of the 1 ppm standard.

3 Sample Preparation

The sample should be diluted 1/4 (1 part resist and 3 parts of solvents weight/weight) in 2-methoxyethanol or another suitable solvent for positive resist. The solvent should contain less than 0.1 ppm of the element being analyzed.

4 Standards

The standards should be weight/weight (mg/kg) and should be diluted weight/weight since results will be expressed in mg/kg.

The standards are prepared by diluting a concentrated stock of organic-soluble sodium and potassium. For example, a 500 ppm standard of sodium is diluted to 50 ppm with reagent xylene. This solution is then diluted to 1 ppm with 2-methoxyethanol or another suitable solvent.

5 Procedure

Set the absorbance reading to zero with the flame ignited and no sample aspirating. Measure the absorbance of the solvent blank. It should not be more than 0.04. Measure the absorbance of the 1 ppm standard and samples. The absorbance of the standard should be in the region of 0.4. Duplicate sample and standard readings should be within 0.01 absorbance. A recovery of 88% was determined when a 1 ppm potassium internal standard was added to the resist tested. The effect of viscosity on delivery to the burner can be determined by adding 2 ppm of a potassium internal standard to the sample and checking the absorbance versus an external 2 ppm potassium standard in the diluting solvent. The potassium level in the resist, if any, should be subtracted.

6 Calculation

$$\text{ppm (mg/kg)} = \frac{\text{Abs. Sample} \times \text{ppm Standard} \times \text{dilution factor} \times \text{R}}{\text{Abs. Standard}}$$

R = Recovery factor due to sample viscosity if applicable, for example 1.136 in above example.

Detection Limit — The detection limit is a function of the dilution factor and can vary by instrument. The dilution factor should be taken into account in calculation of detection limit.

Detection limit (ppm) = s × dilution factor where s = standard deviation of instrument "readings" in ppm.

SEMI P14-0997
DETERMINATION OF TIN IN POSITIVE PHOTORESISTS BY GRAPHITE FURNACE ATOMIC ABSORPTION SPECTROSCOPY

1 Scope

1.1 This procedure is a graphite furnace atomic absorption analytical method for tin in photoresist. The applicable concentration range is 0.1 to 1 ppm when the sample is diluted one to ten. The precision was found to be within 0.1 ppm in a round robin analysis between four laboratories.

2 Instrument Conditions

2.1 An atomic absorption spectrometer equipped with a graphite furnace is used with graphite tubes equipped with pyrrolitically coated graphite platforms for sampling.

2.2 The 224.6 nm emission line from a hollow cathode tin lamp is used as the analytical absorption line.

Furnace Program*

	Dry Step	*Char Step*	*Atomization Step*
Temperature (°C)	110	800	2700
Ramp time (s)	20	20	0 +
Hold time (s)	20	20	5

+ Maximum power heating

* Argon flow rate of 50 mL/min

3 Sample Preparation

3.1 The sample is diluted 1/10 (1 part sample + 9 parts solvents weight/weight) in 2-methoxyethanol or another suitable solvent for positive resist. The solvent should contain less than 0.01 ppm of tin.

4 Standards

4.1 The standards should be weight/weight (mg/kg) and should be diluted weight/weight since results will be expressed in mg/kg.

4.2 A 50 ppm tin standard is prepared by diluting a 500 ppm tin standard in oil to 50 ppm with Xylene.

4.3 A 1 ppm standard is made by diluting the 50 ppm standard in 2-methoxyethanol or another suitable solvent.

5 Procedure

5.1 A 20 µL volume of 1 ppm tin standard is transferred to the platform by Eppendorf pipette. The furnace program is run and absorbance measured. The absorbance of the 1ppm tin standard should be in the range of 0.2 absorbance. Measure the absorbance of the solvent and sample in an identical manner.

6 Calculation

$$\text{ppm tin (mg/kg)} = \frac{\text{Abs. Sample} \times \text{ppm Standard} \times \text{dilution factor}}{\text{Abs. Standard}}$$

6.1 *Detection Limit* — The detection limit is a function of the dilution factor and can vary by instrument. The solution factor should be taken into account in calculation of the detection limit.

6.1.1 Detection limit (ppm) = s × dilution factor where s = standard deviation of instrument reading in PPM.

SEMI P17-92 (Reapproved 0299)
DETERMINATION OF IRON, ZINC, CALCIUM, MAGNESIUM, COPPER, BORON, ALUMINUM, CHROMIUM, MANGANESE, AND NICKEL IN POSITIVE PHOTORESIST METAL ION FREE (MIF) DEVELOPERS BY INDUCTIVELY COUPLED PLASMA EMISSION SPECTROSCOPY (ICP)

This standard was technically reapproved by the Resist Committee and is the direct responsibility of the North American Microlithography Committee. Current edition approved by the North American Regional Standards Committee in October 1998. Initially available at www.semi.org February 1999; to be published February 1999. Originally published in 1992; previously published in 1996.

1 Scope

This procedure is an ICP plasma emission analysis for determination of iron, zinc, calcium, magnesium, copper, boron, aluminum, chromium, manganese, and nickel in photoresist MIF developers. The applicable concentration range and detection limit will depend upon the element and instrument.

2 Spectrometer

An instrument with resolution sufficient to separate the analytical emission lines in Table 1 is required.

Table 1. Analytical Lines of the Elements

Elements Analytical Line	*nm*
Aluminum	396.152
Calcium	317.933
Copper	324.754
Iron	239.562
Boron	208.960
Magnesium	285.213
Nickel	231.604
Zinc	213.856
Chromium	283.563
Manganese	257.610

3 Standards

The standards should be weight/weight (mg/kg) and should be diluted weight/weight since results will be expressed in mg/kg.

The standards are prepared by diluting a concentrated standard. For example, a 500 ppm standard is diluted to 50 ppm with deionized water. This solution is then diluted to 0.25 ppm.

4 Plasma Conditions

The sample is pumped in the region of 0.7 mL/min. usually with a peristaltic pump attached to the nebulizer. The argon plasma flow rate and RF power should be optimized for the sample using settings recommended in the manufacturer manual. Generally, a plasma gas flow rate of 12 L/min and an RF power of 1.25 kW is required.

5 Quantitation

No sample preparation nor dilution is required.

The detector gain is set by measuring the 0.25 ppm standard. The standard should be run intermittently to satisfy reasonable precision. Standard and sample readings should be repeatable within 0.03 ppm. The effect of sample viscosity on delivery of diluted sample to the plasma was not found to be a factor for this procedure. This effect can be checked by adding an internal standard of an element known not to be present in the sample (such as Yttrium) at 1 ppm and checking the emission response vs. an external 1 ppm Yttrium standard.

6 Calculation

$$\text{ppm element (mg/kg)} = \frac{Ix}{Is} \times 0.25 \text{ ppm}$$

Where Ix = emission intensity of sample

Is = emission intensity of 0.25 ppm standard

SEMI P18-92
SPECIFICATION FOR OVERLAY CAPABILITIES OF WAFER STEPPERS

1 Scope

1.1 Definitions for the overlay capabilities of wafer steppers are established, consistent with the primary application of wafer stepper (i.e., the manufacturing of very large-scale integrated circuits). Also included are definitions for associated parameters: registration, exposure field, good fields, and alignment.

2 Applicable Documents

2.1 Statistical methods shall be used in accordance with the procedures in NBS Handbook #91 (Experimental Statistics, by M.G. Natrella) and ASTM STD 15D (Manual on the presentation of data and control chart analysis).

3 Terminology

3.1 *overlay* — a vector quantity defined at every point on the wafer. It is the difference, O, between the vector position, P_1, of a substrate geometry, and the vector position of the corresponding point, P_2, in an overlaying pattern, which may consist of photoresist:

$$O = P_1 - P_2$$

3.2 *interfield overlay* (also referred to as field-to-field overlay) — The center of the lens is chosen to be a reference point. The overlay at the reference point in each exposure field is the interfield overlay.

3.3 *exposure field* — the area of a wafer covered by a single exposure.

3.4 *intrafield overlay* (also referred to as within-a-field overlay) — the overlay within an exposure field, relative to the overlay at the center of the lens reference location.

NOTE: From these definitions, it follows that the overlay at any point on the wafer is the vector sum of interfield and intrafield overlays.

3.5 r*egistration* — a vector quantity defined at every point on the wafer. It is the difference, R, between the vector position, P_1, of a substrate geometry, and vector position of the corresponding point, P_0, in a reference grid:

$$R = P_1 - P_0$$

3.5.1 The reference grid must be clearly specified in any specification of registration.

3.5.2 Interfield and intrafield registration are defined in a manner similar to interfield and intrafield overlay.

3.5.3 Overlay may be computed from registration measurements if the same reference standard is used on all systems for determining registration.

3.6 *alignment* — the mechanical positioning of reference points on the wafers ("alignment targets") to the corresponding points on the reticles. The measure of alignment is the overlay at the position on the wafer where the alignment targets are placed.

3.7 Registration and overlay vectors shall be decomposed into orthogonal components, X and Y, along the directions of the stepper stage motion.

3.8 *good fields* — exposure fields in which the magnitude of the overlay at every point within the field is less than a specified value, V, in both the X and Y directions, exclusive of contributions to overlay from the reticles and non-linear deformations of the wafers during non-stepper processing.

NOTE: It should be recognized that contributions from reticles are non-statistical in nature, and that a particular reticle will make the same contributions to overlay and registration in every exposure field in which it is imaged.

3.9 *fraction of good field* — the overlay capabilities of wafer steppers shall be quantified in terms of the fraction of good fields, F, out of the total number of fields on the wafer:

$$F = \frac{\text{Number of good fields}}{\text{Number of total fields}}$$

Good fields may also be quantified as a percentage (100 * F%).

3.10 Any specification of overlay must define the applicable exposure field size and the stepping patterns on the wafers over which the specification applies. From Sections 3.8 and 3.9 it follows that the specification of the overlay capability of wafer steppers consists of at least two additional numbers, the overlay value, V, and the fraction of good fields, F. It is consistent to characterize stepper overlay capability for multiple overlay values, V_1, V_2, ... with corresponding multiple fractions of good fields, F_1, F_2...

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI P19-92
SPECIFICATION FOR METROLOGY PATTERN CELLS FOR INTEGRATED CIRCUIT MANUFACTURE

Purpose

This document defines several standard test patterns to provide consistent industrywide evaluation and testing of micropatterning equipment, metrology instruments, and processes used in integrated circuit manufacturing.

1 General Specification

1.1 *Scope*

1.1.1 This specification defines the shape, general size, and recommended placement and design rules (where appropriate) of several basic pattern cells for linewidth metrology, resolution testing, and proximity testing. These standard patterns include cells that can be used for optical microscopy, electron microscopy, and electrical probe testing.

1.1.2 This document does not attempt to specify the measurement techniques to be used in verifying critical dimensions for these test patterns on the reticle. Similarly, this document does not attempt to specify how the printed patterns are to be measured on the wafer. This document specifies only what the patterns are supposed to be; it is left to the user to ensure that the actual pattern conforms to this specification, subject to all other applicable SEMI specifications. A separate SEMI document will specify CD measurement conditions (see Section 1.2.1).

1.2 *Applicable Documents*

1.2.1 *SEMI Standards*

SEMI P24 — CD Metrology Procedures

1.3 *Definitions*

linewidth — In semiconductor technology, at a given cross-section of the line, the distance between the airline material boundaries at some specified height above the interface between the patterned layer in which the line is formed and the underlying layer (see Figure 1).

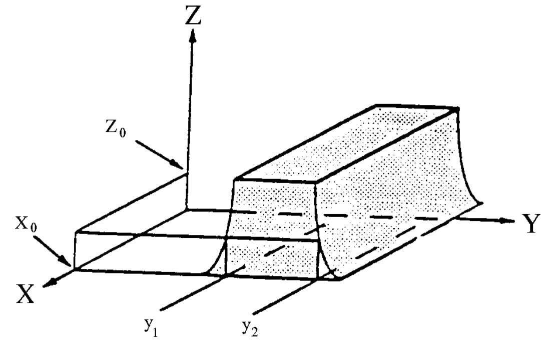

Figure 1
Linewidth (X_0, Z_0) = Y_2 - Y_1

NOTE: The physical basis for various methods of measuring linewidth may result in the measurements being carried out at differing heights for the same line at the same cross-section. For this reason, substantial method-dependent differences in measurement results may be expected and it is convenient to identify the method used in expressions such as "SEM linewidth," "optical linewidth," or "electrical linewidth" (ASTM F 127). Furthermore, the height at which the measurement is taken shall be qualitatively stated, even if it cannot be quantitively determined.

feature — areas within a single, continuous boundary (for example, an aggregate image) that have an optical-density value (gray-level range), that is distinct from the background area outside the feature (ASTM D 3849, D 24) (e.g., the simplest element of a pattern, such as a single line, space, or L-bar).

feature group — a small assembly of one or more similar features arranged together, such as three nested L-bars.

nominal feature dimension — the linear dimension of interest, such as the linewidth or contact hole width.

basic cell — an arrangement of features or groups, as defined by this document, based upon a specific, nominal-feature dimension.

composite cell — an arrangement of several basic cells.

isolated line — a clearfield, dark line as shown in Figure 2 (SYN: island).

Figure 2
Isolated Line

isolated space — A darkfield, clear line as shown in Figure 3 (SYN: window, trench, contact, opening).

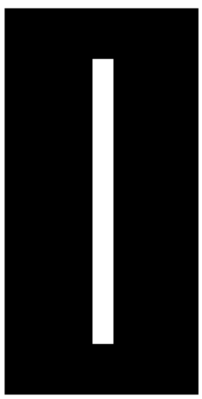

Figure 3
Isolated Space

2 Detail Specification

2.1 *Introduction*

2.1.1 This specification describes the pattern cells, which are illustrated in the figures at the end of this document. These cells are to be placed photolithographically or by other direct patterning methods onto wafer substrates at different masking levels during the IC manufacturing process.

2.1.2 Many details of the pattern cells, such as the orientation, magnitude, range of the linewidths, and polarity of tone (clearfield vs. darkfield) will be defined by the user, unless otherwise noted. When reporting results based on tests using these cells, details such as field polarity, orientation, and topographic considerations must be indicated.

2.1.3 All critical dimensions given in this document are the actual CAD values at 1X. For a given magnification, M, the target dimensions on the reticle should be exactly M times the dimension given in this specification. The reticle dimensions must not be sized to compensate for any wafer process-induced bias.

2.2 *Applications*

2.2.1 These cells are intended to be used in several applications. The following applications list some of the intended uses for the pattern cells.

2.2.1.1 *in-line process monitoring* — To establish patterns to determine if the layer has been processed to design specifications.

2.2.1.2 *process transfer* — To standardize the patterns for process monitoring within manufacturing fabrication sites and to facilitate process and technology transfers between sites.

2.2.1.3 *equipment evaluation* — To standardize the patterns used to evaluate semiconductor equipment.

2.2.1.4 *equipment characterization* — To standardize the patterns for the characterization process of different metrology equipment.

3 Guidelines for Applications

3.1 *General*

3.1.1 The cells described here represent a primary metrology set from which composite patterns may be constructed.

3.1.2 A composite pattern set meets this standard if it consists of any number of the basic cells described herein, provided all design rules for each cell are obeyed.

3.1.3 Each basic cell contains a fundamental design feature. This feature may be repeated at different (user-defined) dimensions within a modified metrology cell. The user will determine all appropriate dimensions for the feature as they apply to specific processing/equipment situations.

3.1.4 The figures provided within this document are intended to illustrate the proper layout of each pattern cell and to define the appropriate design elements used within each basic cell. The pattern cell dimensions are provided when appropriate.

3.1.5 All feature groups must be separated by at least five times the largest feature width. This proximity rule is defined in order to ensure that patterns intended to be independent are indeed non-coupled.

3.1.6 Labels, border lines, indicator marks, or any other adjacent feature will be separated by a minimum of 5 µm.

3.1.7 A label to indicate the nominal feature width must be placed near each basic cell, except the linearity cell, which has no user-defined features. The units of the CD labels must be micrometers and at least two significant figures must be used. The labels must be of a clearly printable size. Decimal points are optional. If decimal points are eliminated, digits to the left of the imaginary decimal point must be slightly larger than those digits to the right. Characters to the left of the decimal are optional. All CD labels that are printed with one size only will correspond to numbers less than 1.0 µm, and any number greater than 1.0 µm must contain at least one character to the right of the decimal place. If the cell includes a bias, a label to indicate this bias, including a "+" sign, must be placed near the basic cell. One significant figure may be used for bias labels if the bias is less than 1.0 µm and a multiple of 0.1 µm. (e.g., + 4 = + 0.4 µm).

3.1.8 It is recognized that there are design limitations dictated by the equipment used to generate the pattern (e.g., CAD grids, PG rectangles, E-beam spot sizes). It is permitted within this standard to modify these cells in order to meet these equipment limitations (e.g., stay on grid).

3.2 *Specific*

3.2.1 *L-Bar Cell* — (See Figure 4.)

3.2.1.1 The L-bar cell is designed to be a measurement site for isolated features as well as line and space groups in orthogonal axes. The cell can be used to measure the quality of pattern transfer and metrology of imaged features. The cell is also a qualitative visual test site for resolution of straight lines and lines bent at right angles.

3.2.1.2 The design elements are the nominal feature width, the inter-feature spacing, the minimum feature length, and the intergrouping linewidth difference (bias).

3.2.1.3 The basic cell consists of one or more groups of nested L-shaped lines at a specific pitch. The pitch is defined at twice the nominal feature width. (See Figure 5.)

W_0 = Nominal feature width

S = Interfeature spacing

L = Nominal feature length

W_0-W_1 = Intergrouping linewidth difference (bias)

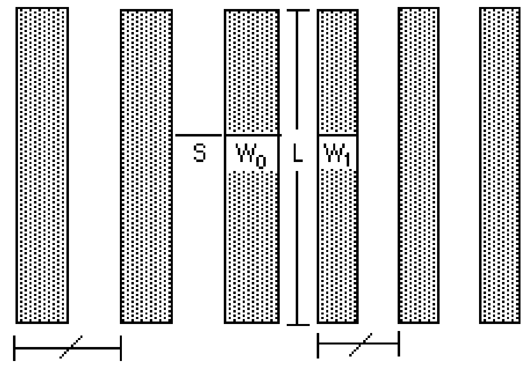

Figure 5

Table 1

Nominal Feature Width	*Number of Nested L-bars*	*Minimum Length*
>1 µm	3	10 W_0
≤1 µm	5	10 µm

The center L-bar of each group shall extend beyond the ends of the other L-bars by at least 10 µm. If these cells are to be used for cross-section analysis, the length of the L-bars may be designed considerably longer than the minimum length.

3.2.1.4 The L-bar basic cell consists of one, three, five, or seven feature groups. If the basic cell only consists of a single feature group, then the lines and spaces must both be equal to the nominal feature width. If the basic cell consists of three, five, or seven groups, then the groups are nested. For the middle group, the lines and spaces must both be equal to the nominal feature width. The feature widths in each successive feature group nested outside the middle group are incrementally increased by the bias. The feature widths in each successive feature group inside the middle group are incrementally decreased by the bias. The pitch for all L-bar groups within a basic cell must be held constant and equal to twice the nominal feature width.

3.2.2 *Straight-Line Cell* — (See Figure 6.)

3.2.2.1 The straight-line cell is a version of the L-bar cell, modified for tilted SEM inspection by removing the elbows.

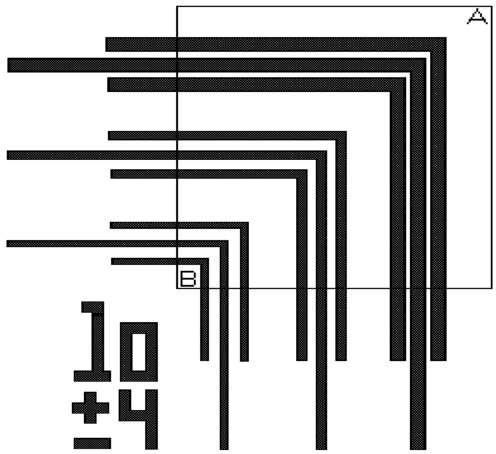

Figure 7
The square area, shown above, is removed to create straight-line cell.

3.2.2.2 To create the straight-line cell from the L-bar cell, the area removed will be a square defined by two diagonal corners referred to as "A" and "B" in Figure 7. Corner "A" is the outer edge of the outermost elbow. Corner "B" is a point inside the innermost elbow whose distance to the nearest edge is five times that of the smallest CD — or 5.0 µm if the smallest CD is less than 1.0 µm. This square area must remain unpatterned.

3.2.3 *Proximity Dagger Cell* — (See Figure 8.)

3.2.3.1 The proximity dagger cell is designed to provide information on the proximity effects of isolated lines/spaces in relation to large area blocks. This cell design allows clear and dark features to be measured simultaneously in one layout.

3.2.3.2 The design elements within the cell are the nominal feature linewidth, the nominal feature spacewidth, and the staircase stepwidth. The stepwidth is user-selected, but it is recommended to be at least 25% of the nominal feature pitch (i.e., pitch equals nominal linewidth plus nominal spacewidth).

3.2.3.3 The cell consists of a nine-tier staircase reproduced symmetrically in both clear and darkfields. A full description of the clearfield staircase (i.e., large chrome islands) is given. The same descriptions apply for the darkfield staircase except the polarities are reversed. Each tier is 10 microns tall. The full width of the cell is 40 microns and the full height is 180 microns. The first tier separates the nominal feature width symmetrically from the large chrome islands by an amount equal to the nominal width. Tiers 2–7 are successively wider by the indicated bias. The 8th and 9th tiers will be 5 and 10 times the nominal feature width respectively.

3.2.4 *Contact Array Cell* — (See Figure 9.)

3.2.4.1 The contact array cell is designed to provide resolution and proximity-effect information over a wide range of contact sizes.

3.2.4.2 The design elements are the nominal square contact dimension, the inter-contact dimension within the 5 × 5 and the 3 × 3 arrays. The latter dimension will be equal to the contact dimension.

3.2.4.3 The contact array cell will consist of three subgroups: a 5 × 5 contact array, a 3 × 3 contact array, and an isolated contact. The 5 × 5 array will produce the maximal proximity (i.e., dense printing) for the center contact. The center contact in the 3 × 3 array will exhibit proximal printing effects different from both the isolated contact and the dense contact.

3.2.5 *Staggered Contact Array* — (See Figure 10.)

3.2.5.1 The staggered contact array cell is designed to improve the probability of cross-sectioning small contacts for SEM metrology analysis.

3.2.5.2 The design elements are the square contact dimension, the column-to-column vertical offset — or staggering — and the contact-to-contact spacing. The contact-to-contact spacing will be equal to the square contact dimension.

3.2.5.3 The contacts are laid out using a minimum of three columns of contacts. The user-selected offset between columns should allow the contacts to remain on grid.

3.2.5.4 The lines (or spaces) shown on the left side of Figure 10 are optional. They have been placed to provide feature identification of pitch calibration. If the widths are to be submicron, 5 lines (or spaces) instead of 3 will be required.

3.2.6 *Linearity Cell* — (See Figure 11.)

3.2.6.1 The linearity cell is designed to test (1) the linearity of the measurement method, assuming the lithographical process is linear over all line sizes used, or (2) the linearity of the process, assuming that the metrological method is linear over all line sizes used.

3.2.6.2 The design elements of this cell are the linewidths, the interfeature spacing, and the minimum line lengths. Unlike the other cells, its elements are not adjusted to a nominal critical dimension, but rather are numerically specified as constants for all applications.

3.2.6.3 The cell consists of nine parallel lines, placed on a five-micron pitch. The linewidths are 1.2, 1.1, 1.0, 0.9, 0.8, 0.7, 0.6, 0.5, and 0.4 microns. The line lengths are a minimum of ten microns. A two-micron top and bottom border (running orthogonal to the parallel lines, across the ends) is provided on the array to allow recognition of the cell as a unit.

3.2.7 *Electrical Cell* — (See Figure 12.)

3.2.7.1 The electrical cell is designed to provide very precise and relatively fast determinations of the average linewidth of a conductive film using an automated test system, but can also be used with a manual prober.

3.2.7.2 The design elements of this cell are the bridge resistor linewidth, W_b, the center-of-tap to center-of-tap bridge length, L_b, the sheet and bridge tap widths, W_c and W_t, the sheet and bridge tap lengths, L_c and L_t, the extension of the bridge resistor line to the nearest discontinuity in that line, L_e, and the size of the square sheet will be 35 – 100 µm. See Figure 13 for the labeling of these elements. The rules for these elements are as follows:

$W_t \leq W_b$ (for $L_b < 100\ W_b$)	(1)
$W_t \leq 1.2*W_b$ (for $L_b \geq 100\ W_b$ and W	(2)
$L_b \geq 15W_b$ for 80 µm, whichever is larger)	(3)
$L_t > 2W_t$	(4)
$L_e > 2W_b$	(5)
$L_c > 2W_c$	(6)

3.2.7.3 The cell consists of two types of four-point Kelvin structures: a van der Pauw sheet resistor and one or more bridge resisitors. The orientation of the individual bridge resistors is user-defined. The bridge resisitors also can be surrounded by dummy lines to measure the process bias due to proximity effect. On structures containing the dummy lines, the interconnects will hook up to the bridge resistor in a perpendicular fashion, as shown in Figure 14.

3.2.7.4 The pad labeled with a V in Figures 13 and 15 will be used for voltage measurement only, and will be used as the fourth point in the sheet resistivity measurements that will be used to make the linewidth determination.

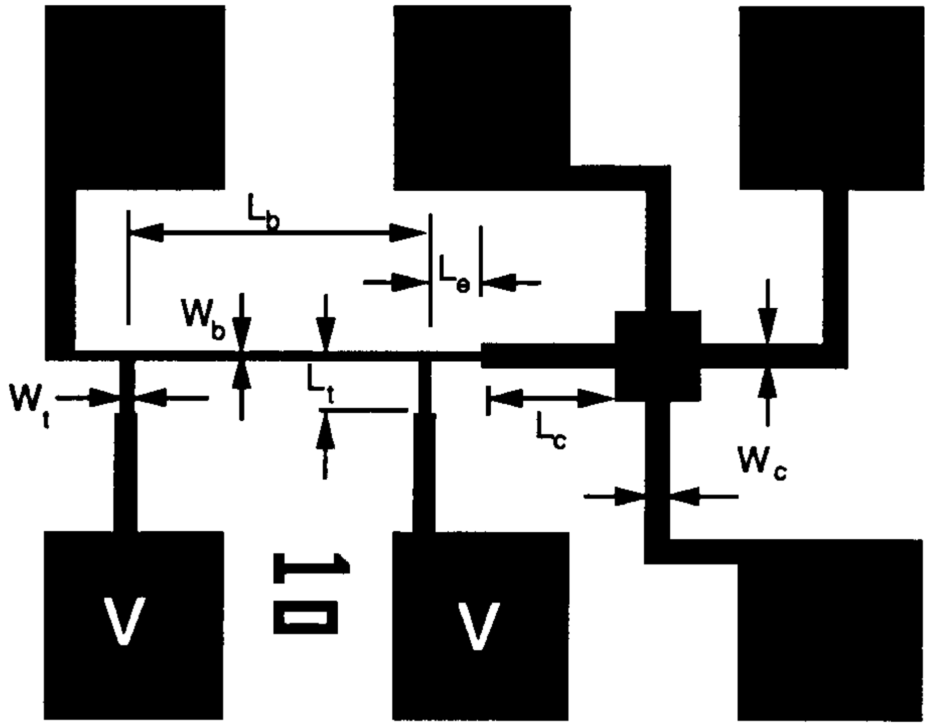

Figure 13
Electrical Cell, 2 × n Configuration with Labeling

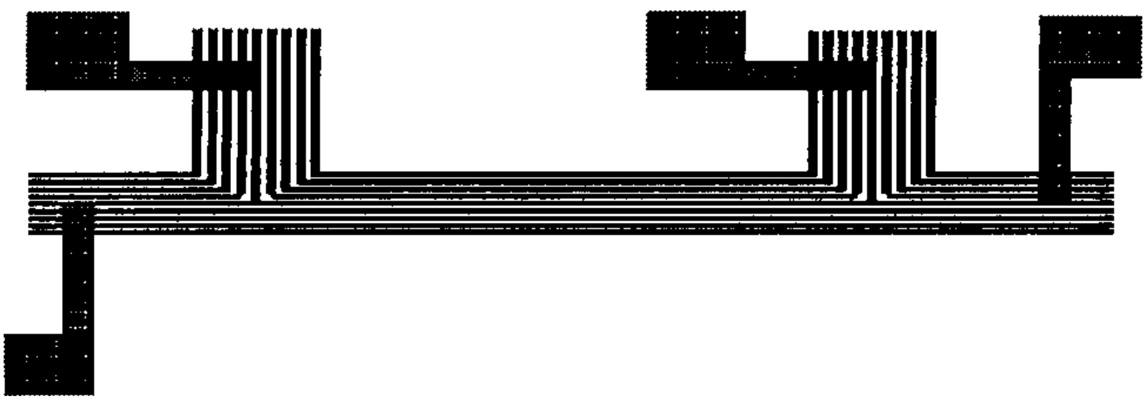

Figure 14
Blow-Up of Bridge Resistor with Proximity Lines

3.2.7.5 The pads can be arranged in a 1 × n layout for scribeline placement (see Figure 15), or the conventional 2 × n layout can be used if the spatial constraints are minimal. Pad size and pitch are user-defined. For automatic testing in a production environment, it is recommended that the pads be 80 – 100 mm per side.

3.3 *User Considerations*

3.3.1 *Target CD versus Resolved CD*

3.3.1.1 The desired size of a critical dimension (CD) on an integrated circuit can be considered its nominal value and is herein designated the "target CD." The size actually achieved (resolved CD) on the circuit may be different from this nominal value.

3.3.1.2 Measurements of the resolved CD may not be accurate because of the difficulty in determining the actual location of the edge in the optical or SEM image profile.

3.3.1.3 Even if inaccurate, measurement of the resolved CD can be valuable for comparison purposes if the measurement method has adequate precision and sensitivity to detect the dimensional changes of interest.

3.3.1.4 The traditional definition of resolution may not be adequate (e.g., ability to distinguish closely spaced points) for specifying the sensitivity to small dimensional changes.

SEMI P20-92
GUIDELINE FOR CATALOG PUBLICATION OF EB RESIST PARAMETERS (PROPOSAL)

1 Purpose

The purpose of this guideline is to provide a baseline for publications of EB resist parameters. It can also be used as a guide to evaluate resist process parameters. This guideline is intended to be applicable for electron beam processes.

The parameters for EB Resist publication are discussed below.

2 Resist Commercial Name

Describe resist commercial name.

3 Resist Properties

3.1 *Polymer Properties*

3.1.1 *Components* — Describe resist components. Chemical structure is not necessarily required.

3.1.2 *Molecular Weight* — Describe M_w, Mn and M_w/Mn if known.

3.1.3 *Thermal Characteristics* — Describe Tg and Tm.

3.2 *Resist Solution Properties*

3.2.1 *Solvent* — Specify chemical names.

3.2.2 *Viscosity* — Solution viscosity, cP, 25°C.

3.2.3 *Solid Content* — Weight %.

4 Film Forming Properties

4.1 *Thickness Curves* — Plot film thickness T (µm or Å) after prebake versus spinning speed R (rpm). Here, x axis is log (R) and y axis is log (T).

4.2 *Conditions* — Specify following conditions.

4.2.1 *Substrate* — Silicon wafer or chrome mask blank. Specify its structure.

4.2.2 *Spinning Conditions* — Specify spinning conditions including coating sequence.

4.2.3 *Environmental Conditions* — Temperature (°C), relative humidity (%).

4.2.4 *Prebake Conditions* — Prebaking temperature (°C), time (sec), heating and cooling method and apparatus. Specify heating rate and cooling rate if monitored.

4.2.5 *Thickness Measurement Methods* — Thickness measurement instruments and measurement method. In case of a light interferance thickness measurement apparatus, specify the refractive index as a parameter used in the measurement.

5 Film Thicknesses

Defines resist thicknesses and measurement conditions for resist parameter descriptions in and after Section 9. Unit is µm or Å.

5.1 *Film Thickness Definitions*

5.1.1 *Ti* — Initial thickness after prebake prior to exposure.

5.1.2 *Te* — Exposed region thickness after development.

5.1.3 *Tu* — Unexposed region thickness after development, and after postbake if required.

5.1.4 *NTe* — Te/Ti. Normalized exposed region thickness.

5.1.5 *NTu* — Tu/Ti. Normalized unexposed region thickness.

5.2 *Thickness Measurement Conditions* — Thickness measurement conditions should be the same as described in Section 4.2.5. In case of measurements of exposed region thickness, exposed region area should be larger than 20 µm on all sides.

6 Sample Preparation

Defines sample preparation methods for resist parameter descriptions in and after Section 9.

6.1 *Film Thickness* — Ti. 0.50 ± 0.20 µm (5000 ± 200 Å) is recommended for a standard thickness.

6.2 *Conditions* — Specify conditions described in Sections 4.2.1 to 4.2.4.

7 Exposure

Defines exposure condition description methods for resist parameter descriptions in and after Section 9.

7.1 *Exposure Dosage Definition* — Quantity of electrical charge per unit area, $\mu C/cm^2$. Describe as D.

7.2 *Exposure Dosage Calculation* — Calculate as follows.

$D = I \times t/S \times 10^6$

Here, I is current (Å), t is exposure time (sec), S is exposure area (cm^2).

Specify these parameters.

7.3 *Acceleration Voltage* — In a range from 10 to 50 kV.

7.4 *Exposure System* — Specify exposure methods.

7.4.1 *Beam Scanning Methods* — For example, raster scanning or vector scanning. Specify beam scanning pitch if defined.

7.4.2 *Beam Shape* — Describe beam shape.

7.4.3 *Beam Conditions* — Specify beam size (µm or **A**) and current density (**A**/cm^2), if possible.

7.4.4 *Exposure Tool Manufacturer and System Name* — Specify exposure tool manufacturer and system name, if possible.

8 Processing and Developing Parameters

This section defines process condition descriptions in and after Section 9.

8.1 *Post Exposure Treatments* — Describe if any treatment is processed after exposure before development.

8.1.1 *Methods* — For example, post exposure bake.

8.1.2 *Conditions* — For example, treatment conditions such as temperature (°C), time (sec), atmosphere, heating method, cooling method and apparatus. Specify heating rate and cooling rate if monitored.

8.2 *Developing Parameters*

8.2.1 *Methods* — Specify spray, dip, or puddle.

8.2.2 *Solution Components* — Specify name of developer and rinse. (Chemical names and weight percent if possible.)

8.2.3 *Temperature* — °C

— For spray, bulk temperature. Processing chamber atmospheric temperature if monitored.
— For dip, solution temperature.
— For puddle, bulk temperature. Processing chamber atmospheric temperature and substrate temperature if monitored.

8.2.4 *Time* — sec.

8.2.5 *Relative Humidity* — %.

8.2.6 *Additional Processes* — Specify if applied.

8.3 *Post bake*

8.3.1 *Conditions* — Temperature (°C), time (sec), heating method, cooling method, and apparatus. Specify heating rate and cooling rate if monitored.

8.3.2 Describe treatment conditions before or after post baking, if applied.

9 Sensitivity Curves

9.1 *Curve Plotting* — Plot NTe as a function of D. Here, x axis is log (D), y axis is NTe.

9.2 *Exposure Dosage Range*

9.2.1 *Positive Resist* — Include dosages larger than a dose gives NTe of 0.

9.2.2 *Negative Resist* — Include dosages larger than a dose gives NTe of 0.7.

10 Sensitivity

A dose required to form a pattern larger than 20 µm on all sides.

10.1 *Positive Resist* — Describe as Dp^0. It gives NTe of 0.

10.2 *Negative Resist* — Describe as $Dn^{0.5}$. It gives NTe of 0.5.

11 Contrast

11.1 *Contrast Definition* — Describe as γ. Calculate from a slope of resist sensitivity curve.

11.2 *Positive Resist (Figure 1)* — Calculate using an angle given from a solid line between NTe of 0 and NTe of 0.8 and a solid line parallel to x axis. Here, NTu should be larger than 0.9.

$$\gamma_p 0-0.8 = \tan\theta = y/x = 0.8/\log\ (Dp^0/Dp^{0.8})$$

11.3 *Negative Resist (Figure 2)* — Calculate using an angle given from a solid line between NTe of 0.5 and NTe of 0.7 and a solid line parallel to x axis.

$$\gamma_n 0.5-0.7 = \tan\theta = y/x = 0.2/\log\ (Dn^{0.7}/Dn^{0.5})$$

12 Resolution

12.1 *Pattern Type and Feature Size* — Lines and spaces. Ratio of lines and spaces should be 1:1. Add hole pattern and isolated pattern if possible.

12.2 *Conditions* — Specify conditions in Sections 6, 7, and 8.

12.3 *Measurement Method* — Measure resolutions using a scanning electron microscope.

13 Nominal Exposure Dosage

13.1 *Nominal Exposure Dosage Definition* — A dose which gives lines and spaces of 3 µm at a ratio of 1:1 under conditions described in Sections 6, 7, and 8.

14 Others

Describe following items if known.

14.1 *Durability* — Wet etching, dry etching.

14.2 *Stability* — Shelf stability, spun film stability, post exposure stability, and post processing stability.

14.3 *Removability* — Describe resist removing method after processing.

14.4 *Remarks* — Describe special characteristics of the EB resist.

14.5 *Cautions* — Describe cautions for safety.

SEMI P21-92
GUIDELINES FOR PRECISION AND ACCURACY EXPRESSION FOR MASK WRITING EQUIPMENT

1 Preface

This guideline describes general requirements concerning precision and accuracy expression of mask writing equipment. Writing accuracy of the mask writing equipment is evaluated by measuring a written mask, and is affected greatly by process conditions to be carried out. Therefore, the writing conditions are to be agreed upon by the user and supplier.

2 Precision and Accuracy Expression Items, Definitions, Measurement, and Requirements

2.1 *Minimum Pattern*

2.1.1 *Definition*

— The minimum line and space pattern and minimum pattern which is possible to be separated

2.1.2 *Expression*

— SEM photograph

2.1.3 *Measurement*

— SEM photograph of the resist pattern or the chrome pattern

2.2 *Pattern Dimension Precision and Accuracy*

2.2.1 *Definition*

— Critical Dimension (CD) variation and deviation of written pattern from designed value.

2.2.2 *Expression*

— Deviation of measured mean value to design value (Δl:μm) and variations (3 σ:μm)

— Measured area and number of sampling point should be clearly described.

2.2.3 *Measurement*

— Optical CD measurement

— Electron beam CD measurement

— CD measurement done by self diagnostic feature of writing equipment

2.2.4 *Requirement*

— Width of a long line pattern in X and Y direction should be measured.

— Pattern types are isolated pattern, 1:1 line and space pattern, or 1:2 line and space pattern.

— The line width to be measured is not specified, but at least three different line widths should be measured.

— Examples of patterns are shown in Figures 1 and 2.

2.3 *Overlay Accuracy*

2.3.1 *Definition*

— Relative deviation of pattern position between two masks

2.3.2 *Expression*

— 3σ:μm (X and Y direction separately)

— Measured area and number of sampling points should be clearly described.

2.3.3 *Measurement*

— Optical coordinates measurement

— Electron beam coordinates measurement

— Coordinates measurement done by self diagnostic feature of writing equipment

2.3.4 *Requirement*

— The pattern should be cross or L mark. Uniform rotation error in measurement should be subtracted from the measurement result.

— Overlay accuracy between different cassette should be clearly described. An example of a pattern is shown in Figure 3.

2.4 *Pattern Stitching Accuracy*

2.4.1 *Definition*

— Position errors at the stitching boundary of writing fields, stripes, and shots.

2.4.2 *Expression*

— |average value| 1 + 3 σμm (X and Y direction separately) measured area and number of sampling points should be clearly described.

2.4.3 *Measurement*

— Optical coordinates measurement

— Electron beam coordinate measurement

— Coordinates measurement done by self diagnostic feature of writing equipment

— Vernier measurement

— Boundary measurement by SEM image

2.4.4 *Requirement*

— The pattern should be cross or L marks in both sides adjacent to the stitching boundary for coordinate measurement

— When the optical microscope is used for measurement, the vernier pattern should be used.

3 Notice

The following subjects should be agreed upon beforehand between users and makers in order to evaluate the above mentioned writing precision and accuracy item.

1. Process Requirements

— Resist Materials

— Coating Condition

— Development Condition

— Process Sequence

— Mask Substrate and Chrome Thin Film Materials

2. Test Pattern

3. Measurement Procedure

4 Others

The following items are not specified in these guidelines, but it is preferable that these items are agreed upon beforehand between user and supplier.

1. Pattern coordinates
2. Pattern position accuracy
3. Long term stability of accuracy
4. Particles

SEMI P22-0699
GUIDELINE FOR PHOTOMASK DEFECT CLASSIFICATION AND SIZE DEFINITION

This guideline was technically approved by the Global Mask & Mask Equipment Committee and is the direct responsibility of the Japanese Mask & Mask Equipment Committee. Current edition approved by the Japanese Regional Standards Committee on March 17, 1999. Initially available at www.semi.org April 1999; to be published June 1999. Originally published in 1993.

1 Purpose

1.1 The purpose of this guideline is to establish standard nomenclature for photomask defect classifications, and to define defect sizing methods.

2 Scope

2.1 It is desirable to follow this guideline when discussing classification, nomenclature, and size of the photomask defects.

3 References

3.1 *SEMI Standard*

SEMI P33 — Provisional Specification For Developmental 230 mm Square Hard Surface Photomask Substrates.

4 Terminology

4.1 *design pattern* — pattern of intended design data.

4.2 *photomask pattern* — pattern on photomask surface.

4.3 Many terms relating to photomask technology can be found in SEMI P33.

5 Classification of the Mask Defect

5.1 *Mask Pattern Defects*

5.1.1 *Shape Defect* — a photomask pattern whose shape is different from its intended design pattern.

5.1.1.1 *Isolated Defect* — shape defects which are isolated from pattern.

1) Dot (See Figures 1, 23)

2) Hole (See Figure 2)

5.1.1.2 *Edge Defect* — shape defects which are adjacent to straight pattern edge.

1) Edge Extension (See Figures 3, 24)

2) Edge Intrusion (See Figure 4)

5.1.1.3 *Corner Defect* — shape defects which are adjacent to corners.

1) Corner Extension (See Figures 5, 27, 29)

2) Corner Intrusion (See Figures 6, 28, 30)

5.1.1.4 *Bridge* — shape defects which are adjacent to more than two edges.

1) Opaque Bridge (See Figures 7, 26)

2) Clear Bridge (See Figure 8)

5.1.2 *Size Defect* — a photomask pattern whose size is different from its intended design pattern.

1) Oversize (on opaque pattern) (See Figure 9)

2) Oversize (on clear pattern) (See Figure 10)

3) Undersize (on opaque pattern) (See Figure 11)

4) Undersize (on clear pattern) (See Figure 12)

5) Elongation (on opaque pattern) (See Figure 13)

6) Elongation (on clear pattern) (See Figure 14)

7) Truncation (on opaque pattern) (See Figure 15)

8) Truncation (on clear pattern) (See Figure 16)

5.1.3 *Misplacement Defect* — a photomask pattern whose placement is different from its intended design. (See Figures 17, 18, 25)

5.1.4 *Transmission Defect* — a photomask pattern whose transmission is different from its intended design.

1) Transmission Defect (on clear pattern) (See Figure 19)

2) Transmission Defect (on opaque pattern) (See Figure 20)

5.1.5 *Missing pattern defect* — a photomask pattern which is absent.

1) Missing opaque pattern (See Figure 21)

2) Missing clear pattern (See Figure 22)

5.2 *Glass Defect* — unwanted defect in (or on) a glass created by various undefined causes (e.g. sleek, pit, scratch, chip, striation, polishing mark, discolor, bubbles, etc.).

5.3 *Miscellaneous Defect* — unwanted clear or opaque spot created by various undefined causes (e.g., crystal growth, electrostatic damage, organic material deposit, Phase shift defect).

6 Definition of Size for Photomask Defects

6.1 The tools and conditions used to measure defect size should be clearly specified.

6.2 *Pattern Defects*

6.2.1 Shape Defects

6.2.1.1 *Isolated Defect* — defect size is expressed as two dimensions (S1 and S2) of the smallest rectangle that encloses the defect. (See Figures 1, 2, 23)

6.2.1.2 *Edge Defect* — defect size is expressed as two dimensions (S1 and S2) of the smallest rectangle that encloses the defect. (See Figures 3, 4, 24)

6.2.1.3 *Corner Defect* — defect size is expressed as the distance (S1) between the intersection point, formed by the bisection of the corner angle and the pattern, and the point designed. (See Figures 5, 6)

6.2.1.4 *Bridge* — defect size is expressed as two dimensions (S1 and S2) of the smallest rectangle that encloses the defect. (See Figures 7, 8, 26)

6.2.2 *Size Defects*

6.2.2.1 *Oversize and Undersize* — defect size is expressed as two dimensions (S1 and S2) representing the absolute value of the deviation from the intended design pattern.

S1 = | b - a |

S2 = | d - c |

"a" and "c" are intended value; "b" and "d" are actual measured value. (See Figures 9, 10, 11, 12)

6.2.2.2 *Elongation and Truncation* — defect size is expressed as two dimensions (S1 and S2) of the smallest rectangle that encloses the deviation from the intended design pattern. (See Figures 13, 14, 15, 16)

6.2.3 *Misplacement Defect* — defect size is expressed as the absolute value of X and Y displacement from its intended position. (See Figures 17, 18, 25)

6.2.4 *Transmission Defect* — transmission defects are evaluated by their transmissivity in addition to the size. The wavelength used for measurement should be clearly specified, as well as the transmissivity error (Te). Defect dimensions should be consistent with other definitions. (See Figures 19, 20)

Te = Td - Ti

where

Td = transmissivity of defect

Ti = intended transmissivity of design

6.2.5 *Missing Pattern Defect* — defect size is expressed as two dimensions (S1 and S2) of the smallest rectangle that encloses the intended design pattern. (See Figures 21, 22)

6.3 *Randomly Shaped Defects* — for the defects which all of above sizing method cannot be applied, defect size is expressed as two dimensions (S1 and S2) of the smallest rectangle that encloses the defect. (See Figures 23, 24, 27, 28, 29, 30)

SEMI P23-0200
GUIDELINES FOR PROGRAMMED DEFECT MASKS AND BENCHMARK PROCEDURES FOR SENSITIVITY ANALYSIS OF MASK DEFECT INSPECTION SYSTEMS

These guidelines were technically approved by the Global Mask and Mask Equipment Committee and are the direct responsibility of the Japanese Mask and Mask Equipment Committee. Current edition approved by the Japanese Regional Standards Committee on September 10, 1999. Initially available at www.semi.org February 2000; to be published February 2000. Originally published in 1993; previously published in 1996.

NOTE: These guidelines were rewritten in their entirety in February 2000.

1 Purpose

1.1 The purpose of this guideline is to propose a test mask to be used for evaluation of the sensitivity of Mask Defect Inspection Systems. This test mask consists of test chips including programmed pattern defects and reference test chips without programmed defects. Since the test chip is an assembly of cells, the test chips are defined in this guideline by cell patterns, programmed defects in cell patterns, and the layout of the cells. Also, the test mask is defined by defining the test chips arrangement. Furthermore, the use of this mask is described. It is desirable that these test masks and benchmark procedures be used when the sensitivity of a Mask Defect Inspection System is evaluated.

1.2 *Background* — Different masks have been used by many equipment manufacturers and users in the past, and sensitivity has been tested by various methods decided independently by each manufacturer and user. In some cases, no common measurement methods or sensitivity analysis methods have been agreed upon. Therefore, confusion exists concerning the sensitivity comparison of equipment between manufacturers, the definition for specifications between users and suppliers, and the definition for specifications between users. Also, due to the fact that several problems were found when using the previous guideline in actual manufacturing, the document has been reviewed and content has been changed throughout. It was also the goal of this revision, while considering ease of manufacturing of test masks first, to fully cover the evaluation of mask defect inspection systems.

2 Scope

2.1 This guideline defines the content and methods for use of test masks used in the evaluation of mask defect inspection systems. Although it is possible to use this test mask to evaluate transcription of defects etc., this standard does not attempt to define these processes.

2.2 This guideline shall be revised when a new effective measurement technology for defect sizing becomes commonly available in the market.

2.3 This guideline does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this guideline to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Referenced Standards

3.1 *SEMI Standards*

SEMI P1 — Specification for Hard Surface Photomask Substrates

SEMI P22 — Guideline for Photomask Defect Classification and Size Definition.

SEMI P33 — Provisional Specification for Developmental 230 mm Square Hard Surface Photomask Substrates

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

4 Terminology

4.1 *Definitions*

4.1.1 Many terms relating to photomask technology are defined in SEMI P22 and SEMI P33.

4.1.2 *design pattern* — pattern of intended design data.

4.1.3 *photomask pattern* — pattern on photomask surface.

5 Mask (See Figure 1)

5.1 Masks will be either 5" or 6" which meet SEMI P1; both the 5" and 6" will be the same layout.

5.2 Masks will be limited to two types, namely Conventional and Attenuated (Half Tone). Note that Levenson and Optical Proximity Correction (OPC) types will not be included.

5.3 There are two types of patterns: Wiring and Contact Hole pattern.

5.4 In one mask, there will be one type of pattern, either Wiring or Contact Hole.

5.5 One defect chip will be placed in the center of the mask.

5.6 Eight reference chips (non-defective) will be placed at 25,000 micron intervals to make sure that inspection can occur even if the mask is set in the inspection equipment in different directions (e.g., 0º, 90º, 180º, 270º).

5.7 *Mask Naming*

5.7.1 Wiring Pattern Mask is "SEMI STANDARD P23-0200-1500W".

5.7.2 Contact Hole Pattern Mask is "SEMI STANDARD P23-0200-1500C".

5.7.3 "P23-0200" is the registered number of this guideline.

5.7.4 "1500" expressed in nanometers, is the photomask pattern design rule. The following explanations in this guideline are based on a 1,500 nm (1.50 micron) design rule.

5.7.5 The mask naming should be written in characters which can be confirmed by the naked eye, and should be displayed in a place recognized by either the manufacturer or user of the mask.

5.8 Four light intensity adjustment patterns will be placed at 12,500 micron intervals from the center of the mask.

5.9 It is feasible to place stepper alignment marks and other patterns in such a way as not to effect the mask pattern described above.

6 Chip

See Figure 2 for illustration.

6.1 One chip of wiring patterns will be made up of 17 types of defects, each at 20 different defect sizes for a total of 340 cells.

6.2 One chip of contact hole patterns will be made up of 14 types of defects, each at 20 different defect sizes for a total of 280 cells.

6.3 Place defects changing types along the X-axis.

6.3.1 Display the defect type from the left side of the chip, toward the right, in capital English letters.

6.3.1.1 Wiring patterns are listed from A to Q.

6.3.1.2 Contact Hole patters are listed from A to N.

6.4 Place defects changing size along the Y-axis.

6.4.1 Place the defects, from top to bottom, in range of size from 0.05 microns to 1.00 microns at 0.05 micron intervals.

NOTE 2: Display all sizes as they pertain to the mask (on the mask).

7 Cell

7.1 One cell will be 250 microns square. (See Figure 3.)

7.2 Sub-cells will be placed 5 by 5 (Total=25).

7.3 Defects will be placed in the center of the cell (± 5.0 micron).

7.4 Cells will be broken up into 9 types, depending on the content of the pattern and defect.

7.4.1 Seven types are used for Wiring Patterns. (See Figures 4, 15 to 21.)

7.4.2 Two types are used for Contact Hole Patterns. (See Figures 6 and 7.)

8 Sub-cell

8.1 One sub-cell is 50 microns square.

8.2 Place a pattern which shows the boundaries of the cell at the sub-cell coordinates (x1,y1), (x5,y1), (x1,y5) and (x5,y5). (See Figures 8 to 12.)

8.2.1 Figure 13 shows an example of these patterns placed together.

8.2.2 The pattern placed at (x5,y1) should be a pattern from which coordinates can be measured.

8.3 Place the defect type ID (cell coordinates) and the abbreviated pattern for the defect type in sub-cell coordinates (x1,y5). (See Figures 8 and 12.)

8.3.1 Defect type ID (cell coordinates) are written as one capital English letter, representing the defect type and a two-digit number representing defect size. (Example: A01)

Character line width is set at 2.00 micron. (See Figure 14.)

8.3.2 The abbreviated pattern which denotes the defect content should keep the defect shape and direction consistent with the shape and direction of the program defect in the design.

8.4 The recommended values for pattern dimensions under the design rule (dimensions on mask) are as follows:

Dimension on Mask	*Mask Name*
5.00 micron	5000
3.00 micron	3000
2.50 micron	2500
2.00 micron	2000
1.50 micron	1500
1.00 micron	1000
0.80 micron	800
0.50 micron	500

8.4.1 The above list of design rule dimensions are recommended values, and it is feasible to use a different size.

8.4.2 When changing the design rule, chip spacing (25.0 mm) should not change.

8.5 For the Wiring Pattern Chip, place a pattern with uniform sub-cell coordinates: (x2,y1), (x4,y1), (x1,y2), (x2,y2), (x4,y2), (x5,y2), (x1,y4), (x2,y4), (x4,y4), (x5,y4), (x2,y5), (x4,y5). (See Figure 4.)

8.5.1 Patterns in a sub-cell using the uniform Wiring Pattern should be as follows:

Sub-cell Coordinates	*Pattern to Be Used*
(x2,y1) & (x4,y5)	Wiring Type A (Figure 15)
(x4,y1) & (x2,y5)	Wiring Type B (Figure 16)
(x1,y4) & (x5,y2)	Wiring Type A rotated 90º
(x1,y2) & (x5,y4)	Wiring Type B rotated 90º
(x2,y2)	Wiring Type C (Figure 17)
(x4,y2)	Wiring Type D (Figure 18)
(x2,y4)	Wiring Type E (Figure 19)
(x4,y4)	Wiring Type F (Figure 20)

8.5.2 Uniform patterns are placed inside a 50 micron-square sub-cell.

8.5.3 For patterns in the Wiring Pattern which change depending on the defect type ID, the same patterns should be placed, without borders, in sub-cell coordinates (x3,y1), (x3,y2), (x1,y3), (x2,y3), (x3,y3), (x4,y3), (x5,y3), (x3,y4) and (x3,y5).

8.5.4 Pattern content will change as follows, depending on the defect type ID:

Defect Type ID	*Pattern to Be Used*
A, B, C, D	Wiring Type A (Figure 15)
G, H, K, L, Q	Wiring Type C (Figure 17)
I, J	Wiring Type D (Figure 18)
E, F	Wiring Type E (Figure 19)
M, N	Wiring Type F (Figure 20)
O, P	Wiring Type G (Figure 21)

8.5.4.1 Adjust the pattern position so that the defect is placed in the center of sub-cell coordinates (x3,y3). There may be instances where the placement of the uniform patterns and the defect-inserted patterns vary slightly.

8.5.4.2 Figure 5 is an example of placement of a Type A Wiring Pattern.

8.6 For Contact Hole Pattern Chips, contact hole patterns should be placed at all sub-cells except coordinates (x1,y1), (x5,y1), (x1,y5) and (x5,y5). (See Figures 6 and 22.)

8.6.1 For misplacement defects, in order to be evaluated as an isolated field, place just one contact hole pattern in the center of sub-cell coordinates (x3, y3) and only in cells where the contact hole pattern defect type ID is “M”. (See Figure 7.)

8.6.2 Adjust the whole pattern for contact hole patterns so that the defect is placed in the center of sub-cell coordinates (x3,y3).

8.7 Use a common spacing for placement of wiring patterns and contact hole patterns.

8.7.1 For placement of patterns in design rule 1.50 microns (on mask), use a spacing of 14.0 microns in the X-direction and 7.0 microns in the Y-direction.

8.7.2 The values for spacing should change accordingly with a change in the design rule.

9 Defect

See Figures 23 and 24 for illustration.

9.1 *Defect Type*

9.1.1 Dot

9.1.2 Hole

9.1.3 Edge Extension

0 degree

45 degree

arctan (1/2) = 26.565 degree

9.1.4 Edge Intrusion

0 degree

45 degree

arctan (1/2) = 26.565 degree

9.1.5 Corner Extension

9.1.6 Corner Intrusion

9.1.7 Over size

9.1.8 Under size

9.1.9 Elongation

9.1.10 Truncation

9.1.11 Misplacement

9.1.12 Missing Pattern

9.2 *Defect Design Method*

9.2.1 Design the following defects, in squares, for wiring patterns and contact hole patterns. For edge defects on diagonal lines, use a pattern designed in a square and rotated to the angle of the diagonal. (In this case, the shape of the defect may change in the design data.) For corner defects, design using the edge length as a design dimension and not the diagonal.

9.2.1.1 Dot

9.2.1.2 Hole

9.2.1.3 Edge Extension

0 degree

45 degree

arctan (1/2) = 26.565 degree

9.2.1.4 Edge Intrusion

0 degree

45 degree

arctan (1/2) = 26.565 degree

9.2.1.5 Corner Extension

9.2.1.6 Corner Intrusion

9.2.2 The following defects change only in the pattern size along the Y-direction.

9.2.2.1 Wiring Pattern Over Size

9.2.2.2 Wiring Pattern Under Size

9.2.3 The following defects change in pattern size along both X and Y.

9.2.3.1 Contact Hole Pattern Over Size

9.2.3.2 Contact Hole Pattern Under size

9.2.4 The following defects change only in pattern length along the Y-direction in both wiring and contact hole patterns.

9.2.4.1 Elongation

9.2.4.2 Truncation

9.2.5 For the following defects, in both wiring and contact hole patterns, move the right half of the pattern in the Y-direction only to form a step.

9.2.5.1 Misplacement Defect with ID ”K”

9.2.6 In the following defects, the pattern shape and size are the same, with one whole isolated pattern moving only in the Y-direction.

9.2.6.1 Misplacement defects, in both wiring and contact hole patterns, which have the defect ID “L”.

9.2.6.2 Misplacement defects, in contact hole patterns, with the defect ID ”M”.

9.2.7 The following single isolated pattern is completely destroyed in both wiring and contact hole patterns.

9.2.7.1 Missing Pattern

9.3 *Fabricating Position for Program Defect*

9.3.1 Fabricate according to Figure detailed drawing.

10 Program Defect Size

10.1 According to SEMI P22, mainly, two values are to be used in defining size of defects. However, for the following reason, one value will be used to describe program defect size on this SEMI Standard P23 mask.

10.1.1 Defects used in evaluation are all program defects and mainly designed in square shape.

10.1.2 When describing the capabilities of mask defect inspection systems, it has become typical to describe defect size which one value.

10.2 Due to various reasons (influences) in mask manufacturing, it is not always possible to form all program defects with the shape and size described in the design.

10.3 SEMI Standard mask defect size is defined as follows. (See Figures 23 and 24.)

Follow SEMI P22 for the values used below (S1, S2, X, Y, a, b, c, d).

10.3.1 *Dot & Hole*

10.3.1.1 Defect Size is S1 or S2, whichever is larger.

10.3.2 *Edge Extension & Intrusion*

10.3.2.1 Defect Size is S2.

10.3.3 *Corner Extension*

10.3.3.1 Defect Size is the difference between the reference pattern S1[Reference] and the defect pattern S1[Defect]

(| S1[Reference] - S1[Defect] |).

10.3.4 *Corner Intrusion*

10.3.4.1 Wiring Pattern

10.3.4.1.1 Defect Size is the difference between the reference pattern S1[Reference] and the defect pattern S1[Defect]

(| S1[Reference] - S1[Defect] |).

10.3.4.2 Contact Hole Pattern

10.3.4.2.1 As with Edge Intrusion in 10.3.2, Defect Size is S2.

10.3.5 *Over Size*

10.3.5.1 Wiring Pattern

10.3.5.1.1 Since size only changes in the Y-direction, Defect Size is (d-c).

10.3.5.2 Contact Hole Pattern

10.3.5.2.1 With “a” and “c” as the reference pattern size, Defect Size is (b-a) or (d-c), whichever is larger.

10.3.6 *Under Size*

10.3.6.1 Wiring Pattern

10.3.6.1.1 Since size only changes in the Y-direction, Defect Size is (d-c).

10.3.6.2 Contact Hole Pattern

10.3.6.2.1 With “a” and “c” as the reference pattern size, Defect Size is (b-a) or (d-c), whichever is larger.

10.3.7 *Elongation & Truncation*

10.3.7.1 Since, in a program defect, the size only changes in the Y-direction (S1), Defect Size is S1.

10.3.8 *Misplacement*

10.3.8.1 Since the program defect is only moving along the Y-axis, Defect Size is Y.

10.3.9 *Missing Pattern*

10.3.9.1 With S1 and S2 as the reference pattern size, Defect Size is S1 or S2, whichever is larger.

11 Light Intensity Adjustment Pattern

11.1 Light intensity adjustment patterns will be placed in four areas in mask defect inspection systems. (See Figure 1.)

11.2 A glass pattern will be placed in the center.

11.3 Around the circumference of the glass pattern, a line and space pattern will be placed, 1 for 1, with the same line width as the design rule (dimensions on mask).

11.3.1 With 500 by 1,250 microns as one block, place horizontal patterns on the left and right sides, perpendicular patterns on the top and bottom. Also, place a horizontal pattern on the lower left corner. (See Figure 25.)

11.4 The circumference of the glass pattern and line & space pattern should have at least 6,000 microns of shade film.

12 Method for Use of Test Masks in Evaluating Mask Defect Inspection System

12.1 Inspect all defect cells, or a portion of them according to the inspection conditions of the mask defect inspection system to be evaluated.

12.2 Perform at least 20 inspections.

12.3 Perform the inspection at least with a set direction of 0º. It is also preferable that the inspection be performed after rotating the set at 90º, 180º, and 270º.

12.4 When displaying the defect inspection sensitivity for mask defect inspection system, display the defect size of the smallest defect of each type which was detected 100%. (See Figures 26 and 27.)

SEMI P24-94
CD METROLOGY PROCEDURES

Introduction

1.1 *Purpose* — The purpose of this document is to establish uniform procedures for metrology systems for the litho-metrology task. It does not address how these systems will be applied to solve problems, nor does it address other contributors to process variations such as thermal wafer processing, exposure tool focus control, materials, etc.

1.2 *Background* — Fundamental to manufacturing is the gauging or measurement process. It is required initially to develop a usable manufacturing capability and then to verify that what is being manufactured conforms to specification/expectation.

1.3 *Scope* — This document discusses determining the performance of gauging/measurement systems for a very specific application — the lithography section of integrated circuit wafer fabrication. This document in many cases, will be applicable to IC mask-making, in which case the word “mask” can be substituted for “wafer.”

It is acknowledged that the final measurement for a fabricated wafer is the electrical functionality. However, the intermediate lithographic measurements can be useful in prediction and control of final functionality. This document is intended to be useful for this litho-metrology application, irrespective of the technology employed.

Measurement results and system performance depend on the sample(s) used. Therefore, performance for different systems or the same system at different times can only be appropriately compared when the measurements are obtained with a sample of the same material composition.

The parameter addressed is precision. Additional important parameters are reliability and cleanliness, which have been addressed by other SEMI standards.

2 Applicable Documents

2.1 *SEMI Documents*

SEMI E10 — Standard for Definition and Measurement of Equipment Reliability, Availability, and Maintainability (RAM)

SEMI P19 — Specification for Metrology Pattern Cells for Integrated Circuit Manufacture

2.2 *ASTM Standards*[1]

ASTM D 1129 — D-29

ASTM C 609 — C-21

ASTM D 4790 — D-16

ASTM E 180 — E-15

2.3 *Applications*

2.3.1 *Linewidth Measurement* — This task is to measure linewidths as defined by SEMI P19.

NOTE: Pitch is not addressed in this document.

2.3.2 *Contact Hole Measurement* — Contact and via hole area measurement is a different application which may use the same definitions and procedures as line-width measurement.

3 Precision

3.1 *Terminology*

3.1.1 *Precision* — The degree of agreement of repeated measurements of the same parameter expressed quantitatively as the standard deviation, computed from the results of a series of controlled determinations [ASTM D 1129, D-29].

A frequency plot of measurements taken with random error illustrates precision. The spread or variation of measurement in test A is smaller than that in test B. The results of test A are more precise than the results from test B. See Figure 1.

NOTE: Any test procedure used needs to differentiate between system and wafer contribution.

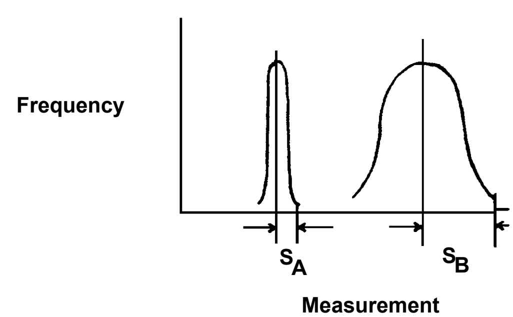

Figure 1
Generic Frequency Plot

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, PA 19428-2959

3.1.2 *Repeatability* — The standard deviation of results obtained by the same operator using the same instrument in successive measurements [ASTM C 609, C-21]. The same system parameters need to be used. The degree to which the individual operator affects the measured result is a critical parameter and must be identified and benchmarked.

NOTE: The degree to which the individual operator affects the measured result may be a critical parameter and must be identified.

3.1.3 *Reproducibility* — The precision of a test method expressed in terms of agreement expected between measurements made in different laboratories using similar apparatus and the same procedure [ASTM D 4790, D-16].

3.1.4 *Stability* — The standard deviation of means of groups of measurements taken at specified intervals over an extended period of time.

NOTE: The means are used to avoid including the measurement precision. Stability is a characterization of the system independent of precision. It is important to use a stable sample so that system stability, independent of the sample, is determined.

3.1.5 *Standard Deviation* — A measure of the dispersion of a series of results around their average, expressed as the square root of the quantity, obtained by adding the squares of the deviations from the average of the results and dividing by the number of observations minus one. It is also the square root of the variance and can be calculated as follows:

$$s = \sqrt{\frac{(x_i = \bar{x})^2}{n-1}} \qquad (1)$$

Where:

s = estimated standard deviation of the series of results

X_i = each individual value

$\overline{X}$ = average (arithmetic mean) of all values, and

n = number of values

The following forms of this equation are more convenient for computation, especially when using a calculator:

$$s = \sqrt{\frac{x^2 - (\ x)^2 / n}{n-1}} \qquad (2)$$

or

$$s = \sqrt{\frac{n \quad x^2 - (\ x)^2}{n(n-1)}} \qquad (3)$$

where:

s = estimated standard deviation

x^2 = sum of the squares of all the individual values

$(\ x)^2$ = square of the total of the individual values, and

n = number of values

NOTE: Care must be taken in using either of these equations that a sufficient number of decimal places is carried in the sum of the values and in the sum of their square so that serious rounding errors do not occur. For best results, all rounding should be postponed until after a value has been obtained for s [ASTM E 180, E 15].

3.2 *Procedures to Benchmark Precision*

3.2.1 *Precision Types*

3.2.1.1 *Static Precision* — A series of measurements made of a single feature where, for each measurement, the information is reacquired and reprocessed. The minimal intervention required to repeat the measurement will be used. The standard deviation will be calculated based on the sample data.

3.2.1.2 *Z (Axis Adjustment) Precision* — A series of measurements is made of a single feature where it is necessary to refocus before each measurement (without intentional movement in the x and y axes before each measurement). The standard deviation will be calculated based on the sample data.

3.2.1.3 *Dynamic Precision* — Make one measurement of grouped line and space features at n number of sites on a focus/exposure matrix wafer, which includes typical size and side wall angle variations. Remove the wafer from the system, then reload and remeasure. Compute the dynamic precision, 3s, by the double sample method (see 2.3.1.3).

A total of 1 size × *n* sites × 2 repeates = 2*n* measurements per wafer × 3 passes = 6*n* measurements required.

10 is a minimum recommended value for *n*.

This may also be redone for different thicknesses of lines to be measured and repeated for each of the wafer types in the process.

3.3 *Precision Test*

3.3.1 *Test Methods*

3.3.1.1 *Stability Test Method* — Make a group of five measurements of a stable feature, such as etched polysilicon, at the same position, daily. Any system adjustment, maintenance, environment variation is allowed, but noted. Recalibration is optional, but is noted. Use a feature which doesn't change over time, or with repeated measurements. Plot the daily averages on an individual control chart with control limits based on the moving range of the daily averages.

3.3.1.2 *Sequence Test Method* — A series or sequence of measurements is taken of the same physical location. Any change between measurements determines the type of precision tested.

3.3.1.3 *Double Sample Test Method* — Two measurements are taken at separate times within the test run at a number of different physical locations. A series of sites is used which have: same nominal size, same proximity of other features, similar side wall angle, etc.

3.3.2 *Test Duration*

3.3.2.1 *Short Term* — No system calibration, adjustment, or maintenance will be done. The period should be short enough to minimize the effect of environmental variations. See R1-1.

3.3.2.2 *Long Term* — Any system adjustments, maintenance, environment variation is allowed. See R1-2. Recalibration is optional.

3.3.3 *Presentation of Results* — Some information, relative to the data, must be included to qualify the results. Graphical representation of the data is recommended.

3.3.3.1 The following must be included:

— The estimated (1, 2, or 3) standard deviation(s),

— Short or Long Term

— Confidence interval (see Application Note A.3)

— The number of measurements or sample size (*n*)

— Describe the feature film and substrate film

— Nominal or average measurement

— Feature Type: line or space or hole, grouped or isolated

— The frequency of recalibration

— Test identified as the type performed

Additional information which should also be included, particularly with unusual conditions, are:

— Metric units are recommended, such as nanometer [nm] or micrometer [µm]

— Feature characteristics, such as: sidewall angle, wall profile, corner radius, materials, thickness, index of refraction, edge waviness, edge roughness

— Duration of the test

— The sample frequency

— Significant parameters such as operator, system model, serial number, pertinent environmental conditions, etc.

RELATED INFORMATION 1

NOTE – The material contained in this related information is not an official part of SEMI P24 and is not meant to modify or supersede the standard in any way. This information is provided as a source of information to aid in the application of the standard. As such, it is to be considered as reference material only. The standard should be referred to in all cases.

R1-1 Short Term Test Duration

It is recommended the short term test duration be 30 measurements done in the shortest possible time under the most limited of conditions to eliminate extraneous sources of variation.

R1-2 Long Term Duration

Common practice requires about 30 degrees of freedom in the highest level of sources of variation. For example, one should continue a long term study over 30 working days, if days is the highest level of variation.

R1-3 Confidence Interval

This is one way in which confidence interval is calculated.

$$\sqrt{\left(\frac{vs^2}{x^2_{v.1-\alpha/2}}\right) \le \sigma^2 \le \left(\frac{vs^2}{x^2_{v.\alpha/2}}\right)}$$

where

v = df in the extimated standard deviation,

α/2 – the alpha risk accepted for the estimate (1-α) is the “confidence level”, and

X^2 refers to the “chi-square” distribution which fits variances. The equation is arranged such that the area under the chi-square distribution is to the right of the designated value.

The reference distribution looks something like Figure R1-1 — its shape depends on the degrees of freedom in the estimate.

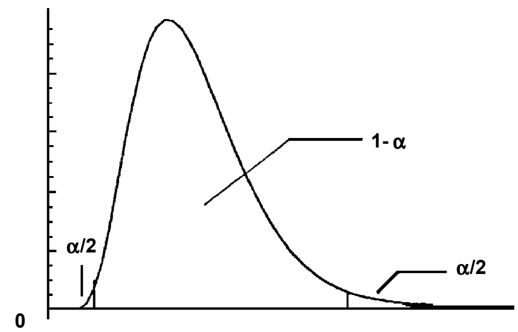

Figure R1-1
Example of a Chi-Square Distribution

It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer’s instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user’s attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI P25-94
SPECIFICATION FOR MEASURING DEPTH OF FOCUS AND BEST FOCUS

1 Purpose

This document provides a common descriptive vocabulary and outline of basic technique for use by photolithographers in the IC industry to gauge and report the depth of focus, astigmatism, and field curvature of IC photolithographic instruments (e.g., scanners, steppers). [Hereafter referred to as "instrument" or "instruments."]

2 Scope

This specification is limited to the measurement of focus and depth of focus for photolithography as used in the manufacture of integrated circuits and closely allied technologies. Because of the wide variation in equipment techniques, it is not possible to provide a definitive measurement procedure for these parameters. Rather, in this document, a basic guideline is offered.

Note: This technique has value in determining the best focus setting for a given application, however the main concern will be the determination for the depth of focus, astigmatism and field curvature for the purpose of comparing different instruments and processes.

3 Limitations

It must be emphasized that the values of depth of focus, astigmatism, and field curvature cannot be determined for a given instrument independent of the effects of the image geometries and the image transfer process. The values will have to be determined under the constraints of a practical application process, suitable for the instrument, illumination, process, object pattern, and environment. Thus, the process to be used for a fair measure of instrument performance must be one that is appropriate and has been optimized for the given instrument and application. Comparison of the performance of two different instruments will inherently be a comparison of the the total application, instrument specific processes included. A description of the process is a necessary part of the report of a depth of focus, astigmatism or field curvature measurement. Relying on values that were obtained under significantly different application conditions from the desired application will result in error and potential unexpected process failure.

4.1 *SEMI Documents*

SEMI P19 — Metrology Pattern Cells for Integrated Circuit Manufacture

5 Terminology

NOTE: The scope of the following definitions does not necessarily cover application outside of the procedures discussed herein. For more universal definitions and discussion, the user is referred to any of the standard optical texts.

image (micropatterning) — Any single geometric form appearing in a layout: (1) drafting — as a part of a master drawing or layout; (2) optical — as projected on a screen or viewed, usually at some magnification or reduction; (3) oxide — as etched in the silicon dioxide layer on an oxidized silicon wafer; (4) photographic — as in a photomask or in the emulsion of a photographic film or plate; (5) as a photoresist, an exposed and developed coating on a substrate.

processed image (micropatterning) — Any single geometric form appearing in the realized pattern or topographical variation in a material surface or material constitution, obtained by a physical process of pattern transference from an optical image.

NOTE: This definition is intended to extend the discussion of depth of focus and focus to include both cases where the images are realized in photoresist films, per the image definition given above, and cases where there may not in fact be a photoresist film involved in the optical pattern transference process. Examples include photoactive chemical vapor deposition and photo ablation.

standard coordinates — A system of Cartesian coordinates with the z axis along the optical axis of the system and with the x and y axes in the flat plane perpendicular to the optical axis. The system user or the supplier will specify the x and y directions in this plane for any particular equipment studies.

NOTE: Upon occasion, cylindrical coordinates may be used for special discussions, for example, mapping astigmatism. The standard transform is used between the Cartesian (x,y) and the cylindrical (r,ø) is used.

NOTE: The x and y coordinates are taken as displacements from the optical axis along a flat plane. Thus, if the image plane is curved, the x and y coordinates are taken from the projection of the curved image plane onto a flat plane.

Consistently, r is taken as the distance along a perpendicular to the optical axis.

NOTE: A displacement along the z axis (and hence the optical axis) from a reference position will be negative for displacements toward midpoint of the optical system and positive for displacements away from the midpoint of the optical system, regardless of whether the reference position is on the object side or on the image side or coincident with some portion of the optical system.

NOTE: For folded optical systems, the coordinate system is allowed to rotate with position along the optical axis so that the above definition holds at any given position along the axis. Alternately, it may be assumed that for purposes of using this coordinate system, all optical paths are represented as unfolded.

image field — The extent of the image along the x and y axes. It may be defined by the limits of image quality, as a practical matter, for the intended application.

NOTE: Definitions 3.1 and 3.2 in combination with 3.4 define the drafting image field, the optical image field, the processed image field, etc. The term "image" refers to a single geometrical form. The term "field" refers to the complete set of forms.

practical use — The conditions of photoprocess, image geometries, etc. that are required for the intended use of the instrument. The practical use is specified by the following:

> *process* — Photoresist type and chemical processing, exposure conditions, and environmental conditions (temperature and humidty setpoints and stability).
>
> *pattern* — Description or diagram of the test structures, including the choice geometrical dimensions, orientations, positions.
>
> *substrate* — The substrate quality and specifications, including all pre-existing structures and layers on the substrate.
>
> *leveling* — The leveling mechanism used to hold the substrate at the desired position and angle with respect to the optical image plane.
>
> *site* — List or map of the image sites in the processed image field used for the tests.
>
> *criteria* — The acceptance criteria used in the evaluation of the processed images.

NOTE: Typically, the instrument vendor will indicate a range of practical use parameters and the instrument user will select from this range the actual conditions, as is appropriate to the user's needs.

resolution, practical — The minimum line width that reproduces the mask (or drafting) dimensions faithfully. [SEMI Micropatterning — Terms and Definitions Relating to the Microlithography Industry]

NOTE: The practical resolution is a number specified by the equipment vendor.

point-like object — A circular or square form in the image where the diameter or width is equal to the practical resolution.

evaluative line pattern — A pattern in the image constructed of 3 to 5 straight parallel lines where the lines are oriented at some specified angle with respect to the standard coordinates and where the width of the lines is equal to the practical resolution and the pitch of the lines is twice the practical resolution. (See SEMI P19.)

saggital lines — An evaluative line pattern where the lines lie along a radius to the optical axis. (See Figure 1.)

NOTE: Saggital lines are primarily formed from light rays that do not lie in planes containing the optical axis. For optical systems having cylindrical symmetry, such as some reduction steppers, the Saggital lines will be radial lines from some particular point of the image field. For other systems the lines may not be radial. For example, the Saggital direction for scanners is perpendicular to the direction of the scan throughout the image field.

tangential lines — An evaluative line pattern where the lines lie perpendicular to a radius to the optical axis. (See Figure 1.)

NOTE: Tangential lines are primarily formed from light rays that do lie in planes containing the optical axis. For systems having cylindrical symmetry, tangential lines lie upon circles about some particular point of the image field. For other systems, the lines may not be so arranged. For example, the tangential direction for scanners is parallel to the direction of the scan throughout the image field.

focus — A condition of geometric adjustment of the lens's object, the optical system and the image plane such that the optical image rays originating from a given point in the object converge to the smallest possible area at the corresponding point in the optical image. It is always given as a numerical displacement of the optical image point along the optical axis from some arbitrary reference such as an optical exit surface, optical center, conjugate plane, etc. Focus may vary across the image field and is properly given as a z axis value for a specified image site in the image field. (See the definition for Focal Surface.)

NOTE: Point-like objects will have the sharpest optical image at this z-axis position. The z-axis position for the sharpest processed image of point-like objects will usually have a constant offset from the z-axis position for the sharpest optical image for point-like objects. (See “mean focus” and “best focus” definitions that follow in the text.)

NOTE: This is also the position which yields the highest contrast in the photon flux at the given point in the optical image.

line focus — The z axis position where for evaluative lines in the image, the optical image has the highest contrast and the evaluative line pattern will consequently appear with the correct width and pitch. Line focus may vary across the image field and is properly given as a z axis value for a specified image site in the image field. It also varies with the line angle, and the line focus must, therefore, include a specification of the angle (e.g., Saggital, tangential, or some other angle).

focal surface — The surface determined by finding the focus for each point-like object in the optical image field, with the object fixed with respect to the lens. The focal surface is then the map of z axis displacements for the highest contrast at each point in the optical image field as a function of the (x,y) or (r,ø) coordinates.

NOTE: It is important to remember that the unqualified focal surface is determined using point-like objects, not lines or gratings. Separate determinations must be made for non-point-like objects.

field flatness — The difference between the maximum and the minimum z axis positions over the focal surface.

saggital focal surface — The focal surface determined by examining only Saggital lines.

tangential focal surface — The focal surface determined by examining only the tangential lines.

normal astigmatism — The difference in z axis position at each image site between the Saggital focal surface and the tangential focal surface. Astigmatism is a map of scalar values over the (x,y) coordinates of the image field.

rotated astigmatism — At each image site, the z axis difference for the line focus of two evaluative line sets, oriented at right angles to each other and at some specified angle to the coordinate system, where the specified angle is selected so that the z axis focus difference is a maximum at the given image site. The specified angle may vary from image site to image site.

NOTE: This is called “rotated” astigmatism because the specified angle is not necessarily the Saggital or tangential direction.

mean focus — The z axis position representing the area average focal surface for point-like objects in the optical image.

best focus — A position of the processed image surface such that the best compromise of focus across the whole of the processed image is obtained, as defined by the application requirements upon the processed image. The best focus is a single numerical value for the processed image surface displacement. The best compromise may be such as to optimize the possible defocus range or may optimize the line width variations or may minimize the deviation from some target width or may relate to some other processed image parameter.

NOTE: Because of processing effects, this may or may not correspond to an optical conjugate plane coincident with the photoresist film or other processed layer — top, middle, or bottom.

NOTE: Because the processed image surface will generally have a curvature that is not adjustable, it is not usual for the processed image surface to fully correspond to any of the focal surfaces. Focal surfaces are defined by determining the z-axis position for a given focus condition, as a function of the image position. A processed image surface is therefore set at a z axis position that provides the best compliance to the focal surface.

defocus — The distance, perpendicular to the image plane, between the processed image plane and the plane of best focus.

NOTE: A defocus of zero is the best focus position, a positive defocus places the optical image plane further from the lens, a negative defocus places the optical image plane closer to the lens.

focal range — Depth of focus — the total distance of defocus where over the whole of the processed image field, the processed image is sufficiently resolved for practical use.

depth of focus map — A plot, for each position in the image field, of the greatest defocus in the positive direction and the greatest defocus in the negative direction, where the processed image is sufficiently resolved for practical use.

NOTE: As stated previously, the focal range or the depth of focus are dependent on the process, upon the image geometries (especially the line width), and upon the permissible deviations. The depth of focus maps may be dependant, among other things, on the process, line width, and image geometry, especially the choice of point-like patterns or line-like patterns along the Saggital, tangential, or other directions. Several maps may be produced as part of a test, covering these variations.

6 Procedure

6.1 *Pattern* — See SEMI P19. A pattern and pattern dimensions are to be selected in accordance with the most reasonable correspondence to the intended application of the equipment. Typically, the pattern will consist of two sets of evaluative lines. A sequence of patterns of varying line widths may also be employed, in which case the depth of focus may be reported as a function of the line width. The pattern selection and dimensions must be included as part of the report.

6.2 *Test Sites* — The pattern is to be repeated at least nine times over the image field. The minimum of nine sites will include the four corners of the image, the four edge midpoints of the image field and the center of the image field. Whichever many sites are used, the sites must be distributed symmetrical and uniformly over the image field, giving no special weight to any portion of the image field. For examples, see Figure 2.

6.3 *Process* — A test image will be printed under the same conditions and processes to be used in the practical application (see Section 2) of the instrument (stepper, scanner, etc.). The process description will be included in the depth of focus and best focus report.

6.4 *Focus Steps* — The image will be printed several times, varying the defocus by a fixed amount between each print. The amount of variation of defocus between steps and the limits of the defocus will be selected so as to bracket the expected best focus position and to reach beyond the depth of focus at the extremes of the image series, as best as can be determined. The number and size of the defocus steps must be specified in the report.

6.5 *Image Array* — These multiple images can be a row of separate exposure fields on one substrate, multiple stepped displaced exposures of the test geometry within one image field region, or even exposures on entirely separate substrates. The particular strategy is usually constrained by the functions of the instrument under test.

6.6 *Test Measurements* — For each image site for both test pattern orientations and at each value of defocus, the processed image geometries will be examined and either accepted or rejected on the basis of image sharpness, image size or some related image characteristic. Usually this examination will use the line width as the acceptance criteria. The total number of the measurements will be twice the number of sites times the number of defocus steps.

6.7 *Quantitative Image Evaluation* — The photoresist image patterns will be examined or measured for deviation from the target, in a manner specified by the vendor or user of the instrument. An acceptable image is where the variation of the pattern is not outside the permissible deviation under the conditions of the intended use of the equipment. The defocus values for which the image is usable will be determined at each image site within the image field.

6.8 *Depth of Focus and Best Focus Determination* — The defocus variation over which there are usable images at simultaneously every test site within the field, by the above criteria, will be reported as the practical focal range. In accordance with the definition, the best focus will be the z axis position where some target specification is met or the possible defocus is maximized or the line deviation minimized, etc. If there is no common range of usable defocus across the the field, the depth of focus is zero and the best focus is undetermined. This can occur due to, among other things, a large plane tilt of substrate to the optical axis, high aerial image focus surface curvature, high astigmatism, and auto focus system instabilities.

6.9 *Focal Astigmatism Determination* — The test measurements are separated into two groups, one group for each of the two different orthogonal orientations of the test pattern. These groups are referred to as the “S” and “T” groups, however the Saggital and tangential orientations have not necessarily been used in accordance with the definition of “rotated astigmatism.”

For each group separately, the focal surface is determined by using for each site the midpoint of the defocus values where the processed image is found to be acceptable, in accordance with Section 4.7.

The difference in z position between these surfaces for each image site is calculated. These differences are plotted as a function of image position. This map of values is the astigmatism.

The maximum of the absolute values is the maximum astigmatism.

The average of the absolute values is the mean astigmatism.

6.10 *Field Flatness Determination* — Two alternative but essentially equivalent methods of determining the focal surface are allowed:

a. The focal surface which is the midpoint of the S and T focal surfaces is calculated.

b. Alternatively, if point-like objects are available in the image for evaluation, the focal surface may be obtained by finding the z displacement for the best processed point image at each image site.

This focal surface is reported as a map of z displacements as a function of image position. This map is the curvature of field.

The difference between the minimum z displacement in the focal surface and the maximum z displacement in the focal surface is the maximum curvature of field.

NOTE: This includes optical image curvature, wafer curvature, fixture curvature, etc. This procedure for the sake of simplicity does not separate these effects. It is an error to consider this measure of field flatness equivalent to a measure of the optical image focal surface.

7 Report

The depth of focus, best focus, etc. reports will include a description of the practical use, per definition 3.2.5. In addition, the report should include mention of any special mechanical considerations — in particular, among others, mention should be made if a chip leveling scheme is used and whether this scheme is site by site or global.

List of report contents:

Process: substrate and layer types and processing, exposure conditions

Pattern: description or diagram of the test structures, including the choice of S and T or X and Y orientations

Wafer: the wafer quality and specifications.

Leveling: leveling mechanism.

Sites: list or map of the image sites.

Criteria: the acceptance criteria used in the evaluation of the test structures.

Depth of Focus or Focal Range (single overall values)

Best Focus (single overall value)

Astigmatism map

Maximum Astigmatism

Mean Astigmatism

Field Flatness map

Maximum Curvature of Field

SEMI P26-96
PARAMETER CHECKLIST FOR PHOTORESIST SENSITIVITY MEASUREMENT

1 Purpose

1.1 This checklist identifies the parameters for the measurement of photoresist sensitivity in order to avoid the variations between the supplier and users of photoresist.

2 Scope

2.1 The resists for which this guideline is intended are positive photoresist, excluding chemically amplified resists, for which the evaluation method of the sensitivity characteristics is not established.

2.2 In discussions between the supplier and the user of the resists, quantitative values should be provided for each parameter.

3 Referenced Documents

3.1 *SEMI Standard*

SEMI P27 — Parameter Checklist for Resist Thickness Measurement on a Substrate

ASTM[1]

ASTM F1059 — Practice for Calculating the Contrast and Threshold Sensitivity of a Positive Photoresist

4 Terminology

4.1 E_{th} *(threshold energy)* — The exposure energy where the remained thickness ratio becomes zero on the sensitivity curve.

4.2 E_{op} *(optimum energy)* — The exposure energy where the mask dimensions can be reproduced faithfully.

5 Parameters

5.1 *Substrate* — Silicon wafer

5.2 *Pre-Treatment of Substrate*

5.2.1 Removal of native oxide on silicon wafer is recommended.

5.2.2 Describe the process when the surface of silicon wafer has been treated with HMDS.

5.3 *Resist*

5.3.1 Trade-name of photoresist.

5.3.2 Film thickness after prebake. (Recommended thickness is 1.0–1.2 µm.)

5.4 *Prebake Condition*

5.4.1 Type of equipment for prebake; contact or proximity-bake.

5.4.2 Measuring position of the temperature in baking equipment and equipment for temperature measuring.

5.4.3 Baking time (sec).

5.4.4 Program sequence.

5.5 *Exposure*

5.5.1 Type of exposure machine; stepper or mirror projection.

5.5.2 Wavelength and half width (nm).

5.5.3 Light intensity of the exposed surface (mW/cm^2).

5.5.4 Numerical Aperture and sigma value.

5.6 *Post-Exposure Bake (if performed)*

5.6.1 Type of equipment for post-exposure bake; contact or proximity-bake.

5.6.2 Measuring position of the temperature in baking equipment and equipment for temperature measuring.

5.6.3 Baking time (sec).

5.6.4 Program sequence.

5.6.5 Film thickness after post-exposure bake.

5.7 *Development*

5.7.1 Type of developer; commercial name and chemical composition.

5.7.2 Concentration of developer (weight % or molar %).

5.7.3 Dilution factor.

5.7.4 Method; Spray (nozzle type, rotation speed, flow rate of developer), Puddle (program of sequence).

5.7.5 Temperature of developer, room temperature.

5.7.6 Development time (sec).

5.8 *Postbake*

5.8.1 Type of equipment for postbake; contact or proximity-bake.

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohoken, PA, 19428-2959

5.8.2 Measuring position of the temperature in baking equipment and equipment for temperature measuring.

5.8.3 Time (sec).

5.8.4 Program sequence.

5.9 *Measuring Equipment*

5.9.1 Specify the measurement system for the film thickness measurement.

5.9.2 Specify the measurement system for the pattern width measurement.

5.10 *Other* — Line-width of pattern in the reticle affects to E_{op}. The use of reticle with the width accuracy of ± 5/100 µm to the pattern, or co-share of reticle for the crosscheck is recommended for the purpose of this guideline.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. SEMI P27-96
PARAMETER CHECKLIST FOR RESIST THICKNESS MEASUREMENT ON A SUBSTRATE

1 Purpose

1.1 This checklist identifies the parameters for the thickness measurement of single layer resist on a substrate. Several methods are known for the thickness measurement of thin films, among them two methods are widely used for the thickness measurement of resist films.

1.2 They are the surface profilemeters which use mechanical contact method to detect the topology of a surface, and the light interference method which can be used only for transparent films.

1.3 The contacting method has more accuracy than light interference method, but the precision of the measurement is limited. The light interference method shows much more precision than the other but the results depend on measuring conditions.

2 Scope

2.1 This guideline describes on the parameters for the thickness measurement of single layer resist in lithography process.

2.2 For example, pre-expose resist thickness measurement on a bare silicon wafer for the QC of an optical resist, or the resist thickness measurement of partially exposed and fully exposed films after development for the determination of a characteristic curve of a resist.

3 Referenced Documents

3.1 *ASTM*[1]

ASTM F804-83 — Standard Practice for Producing Spin Coating Resist Curves, 7.4 Thickness Measuring Instrument

4 Parameters for Contact Type Measuring Instruments (Surface Profilometer)

1. Name of the instrument used for the measurement
2. Pressure of the stylus
3. Radius of curvature of the stylus tip
4. Type of substrate
5. The method of making a scratch on the surface of the resist
6. Temperature and relative humidity of the room

NOTE: The stylus pressure should be so adjusted that it does not leave a visible indented track mark on the resist surface at × 50 optical microscope magnification.

5 Parameters for Light Interference Thickness Measurement Apparatus

1. Name of the apparatus used for the measurement
2. Refractive index or Cauchy indexes of the resist used as the parameter of the measurement

$$n = A + \frac{B}{Y^2} + \frac{C}{Y^4}$$

where

A, B, C = Cauchy indexes

n = refractive index

Y = wave length

3. The range of wave length used for the measurement should be specified. Type of the substrate. Surface condition, cleaning method and the refractive index of the substrate if available.
4. Magnification setting
5. Type of optical filter
6. Temperature and relative humidity of the room

SEMI P28-96
SPECIFICATION FOR OVERLAY-METROLOGY TEST PATTERNS FOR INTEGRATED-CIRCUIT MANUFACTURE

1 Purpose

1.1 This document defines several standard overlay-metrology patterns that are used by metrology equipment users to evaluate and test micropatterning equipment and processes in integrated circuit (IC) manufacturing. These overlay cells may be placed by optional patterning methods onto substrates during the manufacturing process. Usage of the standard overlay patterns is an attempt to provide consistent industrywide use of automated metrology equipment.

2 Scope

2.1 This specification defines general designs that describe the shape, size, design rules, and placement considerations (where appropriate) of several basic patterns for overlay metrology. These standard test patterns can be used for optical, scanning electron beam, and other types of metrology.

3 Limitations

3.1 The patterns described in this document represent the first pass at an industrywide commonality for the purpose of compatibility among various types of automated metrology equipment. It is not suggested, however, that these test patterns are a full complement or are optimal for all overlay-metrology applications. This document does not attempt to specify how the patterns are to be imaged or measured on the substrate.

F 127-84 — Definition of Terms Relating to Photomasking Technology for Microelectronics

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohoken, PA 19428-2959

5 Terminology

5.1 *centerline* — a reference line that is equidistant from opposite edges of a feature.

5.2 *feature* — areas within a single continuous boundary (for example, an aggregate image) that have any physical property that is distinct from the background area outside the feature (e.g., the simplest element of a test pattern, such as a single line or bar). Some physical properties that may distinguish the feature are the refractive index, surface roughness, etc.

5.3 *feature dimension* — the dimension of interest; such as, the side of a box , bar width, and/or length.

5.4 *overlay (micropatterning)*

A vector quantity defined at every point on the wafer. It is the difference, O, between the vector position, P_1, of a substrate geometry, and the vector position of the corresponding point, P_2, in an overlaying pattern, which may consist of photoresist. [SEMI P18-92]

NOTE: All overlay test patterns are designed to provide both X and Y components of the vector overlay.

5.5 *pattern, overlay test* — a group of features for overlay metrology.

5.6 *pitch* — the distance between a point on an image and the corresponding point on the corresponding image in an adjacent functional pattern.

5.7 *substrate (materials)* — in semiconductor technology, a wafer that is the basis for subsequent processing operations in the fabrication of semiconductor devices or circuits. [ASTM F 1241-89] NOTE: The meaning of substrate is not limited to wafers.

6 General Specification

6.1 *Introduction*

6.1.1 This specification describes the overlay test patterns that are illustrated in the figures at the end of this document. The imaging means by which these test patterns are defined on the substrate may be selected by the user (see 6.2.1).

6.1.2 Characteristics of the overlay patterns, such as materials, topography, polarity, and method of pattern transfer will be defined by the user unless otherwise noted. When reporting measurements extracted from these overlay test patterns, the user should state the physical conditions (e.g., photoresist island on metal over an oxide window). The user should further state which features constitute the substrate geometry and which constitute the overlaying pattern (terms as used in the definition of overlay in 5.4). In general, the vectors P1 and P2 terminate at the geometrical centers of the substrate pattern and the overlaying pattern respectively.

6.2 *Applications*

6.2.1 The overlay test patterns are intended to be used in a variety of applications. The following applications list shows some uses for the overlay test patterns.

- Primary Pattern Generation
- Lithography & Metrology Equipment Characterization
- In-Line Process Overlay Monitoring
- Manufacturing Characterization
- Process Transfer Between Manufacturing Sites

6.3 *Guidelines*

6.3.1 The overlay test patterns described herein represent a basic metrology set from which composite patterns may be constructed.

6.3.2 Each overlay test pattern has a fundamental design. The user may adjust the dimensions appropriately as they apply to the user's specific processing/equipment situations.

6.3.3 It is required that labels, border lines, indicator marks, or any other adjacent features be avoided, or at least separated by a minimum of ten (10) micrometers from the overlay cell. This proximity guideline is defined to remind the user that patterns intended to be independent and symmetric be designed as circumstances permit. The user should determine actual spacing values, because spacing may be level-, process-, and/or tool-dependent.

6.3.4 It is recognized that there are design limitations dictated by the equipment and processes used to generate the pattern (e.g., computer aided graphics (CAD) grids, pattern generation (PG) rectangles, E-beam spot sizes). The user may modify the overlay test patterns in order to meet equipment limitations (e.g., stay on grid) provided that the resulting patterns or their representations retain the designed structures and symmetry.

7 Detailed Specification

7.1 *Introduction*

7.1.1 The figures provided within this document are intended to illustrate sample layouts of several overlay test patterns, and to define appropriate design elements used within each. The overlay test pattern dimensions are provided when appropriate. It is understood that, to optimize the test pattern's performance in a specific application, the user may deviate beyond this standard.

7.2 *Specific Overlay Patterns* — All patterns have 90° rotational symmetry.

7.2.1 *Box-in-Box (see Figure 1)*

7.2.1.1 The box-in-box test pattern is designed to be a test pattern for overlay measurement on metrology equipment. This is the simplest possible design presented.

7.2.1.2 The box-in-box test pattern consists of two square features. Each box is normally defined by a different imaging step; that is, one box corresponds to the substrate geometry and the other box corresponds to the overlaying pattern (5.4). The two boxes are designed to be concentric.

7.2.1.3 The design elements are the feature dimensions of the outer box, B_o, and of the inner box, B_i. The dimensions should follow these guidelines:

outer box: $B_o = 12 – 30$ micrometers (µm)

inner box: $B_i = B_o/2$

These specifications define a range of box sizes and their interfeature spacing. Users should modify the box-in-box dimensions as dictated by design rules, process, and/or measurement equipment requirements. The user should recognize that edges in close proximity may cause measurement errors.

7.2.2 *Frame-in-Frame (see Figure 2)*

7.2.2.1 The frame-in-frame test pattern is designed to be a test pattern for overlay measurement on metrology equipment. It has two designed edges per axis on each side of each imaged step. The additional information gained by having two features on each level, each with a centerline, may reduce the measurement uncertainty as compared to the box-in-box design.

7.2.2.2 The design elements are the pitch of opposite members of the outer frame (F_o), the pitch of opposite members of the inner frame (F_i), and the widths of the frames (W_o and/or W_i) as shown in Figure 2. Each frame is normally defined by a different imaging step; that is, one frame corresponds to the substrate geometry and the other box corresponds to the overlaying pattern (see 5.4). The frames are designed to be concentric.

7.2.2.3 The design elements are the outermost dimension of the outer frame (F_o), the outermost dimension for the inner frame (F_i), and the width(s) of the frames (W_o and/or W_i). The dimensions should follow these guidelines:

outer frame: F_o = 15–30 micrometers (µm)

inner frame: $F_i = F_o/2$

width: W = 1.0–1.5 µm for $F_o \leq 24$ µm, or 1.5–2.0 µm for $F_o \geq 24$ µm

NOTE: The width of the inner and outer bars may differ.

These specifications define a range of frame sizes and their interfeature spacing. Users may modify the frame-in-frame dimensions as dictated by design rules, process, and/or measurement equipment requirements.

7.2.3 *Bars-in-Bars (see Figure 3)*

7.2.3.1 The bars-in-bars test pattern is designed to be a test pattern for overlay measurement on metrology equipment. Each axis has two designed edges per axis on each side of each imaging step. The additional information gained by having two features on each level, each with a centerline, may reduce the measurement uncertainty as compared to the box-in-box design.

7.2.3.2 The overlay test pattern consists of two sets of bars, the outer set and the inner set. Each set of bars is arranged to form an overlay measurement frame as shown in Figure 3. Each bar-in-bar set is normally defined by a different imaging step; that is, the set of inner bars corresponds to the substrate geometry and the set of outer bars corresponds to the overlaying pattern (5.4), or vice versa. The two sets of bars are designed to be concentric.

7.2.3.3 The design elements are the pitch for the outer set of bars (B_o), the pitch for the inner set of bars (B_i), the length of the outer bars (L_o), the length of the inner bars (L_i), and the width(s) of the bars (W_o and/or W_i). The overlay test pattern dimensions should follow these guidelines:

outer bar set: B_o = 15–30 µm

inner bar set: $B_i = B_o/2$

outer bar length: L_o = 50%–70% B_o

inner bar length: L_I = 50%–70% B_i

width: W = 1.0–1.5 µm for $B_o \leq 24$ µm, or 1.5–2.0 µm for $B_o \geq 24$ µm

NOTE: The width of the inner and outer bars may differ.

These specifications define a range of box sizes and their interfeature spacing. Users may modify the box-in-box dimensions as dictated by design rules, process, and/or measurement equipment requirements. The user should recognize that edges in close proximity may cause measurement errors.

7.3 *User Considerations for Overlay-Metrology Equipment*

7.3.1 *Pattern Acquisition* — To ensure automatic acquisition of the desired overlay test pattern by an image-based automated overlay metrology equipment, one or more of the following may be required:

1. Separation of each overlay test pattern as required per metrology equipment specification.
2. Use of only one overlay test pattern in the measurement field-of-view.
3. Printing unique labels next to each overlay test pattern using the proximity guideline in Section 6.3.3.

7.3.2 *Feature Dimensions* — For each overlay test pattern, only a range of feature dimensions is defined (e.g., paragraph 7.2.2.3). The user and supplier together should determine that the dimensions of the overlay test patterns they select are those that consider design rules, the user's process capability, and limitations of the microlithography and measurement equipment.

7.3.2.1 *Width Dimensions* (frame-in-frame or bars-in-bars test patterns) — When all features of the overlay test pattern are imaged at the same process step, the widths of the inner and outer features are recommended to be equal, and of the same polarity, in order to minimize overlay-measurement errors.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI P29-0997
GUIDELINE FOR DESCRIPTION OF CHARACTERISTICS SPECIFIC TO HALFTONE/ATTENUATED PHASE SHIFT MASKS AND MASK BLANKS

1 Purpose

1.1 This guideline defines the characteristics specific to halftone/attenuated phase shift masks and mask blanks.

1.2 This guideline is intended to provide a baseline for specification of phase shift masks and mask blanks to be agreed between the supplier and user.

Because the phase shift mask is still under development, it may be needed to continue the research activity to standardize a final specification.

2 Scope

2.1 This guideline applies to halftone/attenuated phase shift masks and mask blanks for g-line, i-line, KrF, ArF, and/or DUV wavelengths.

2.2 These types of masks can be called either halftone or attenuated phase shift masks. This guideline uses “halftone phase shift masks” as the nomenclature.

2.3 Items not described in this guideline shall conform to SEMI P1.

3 Referenced Documents

NOTE: As listed or revised, all documents cited shall be the latest publications of adopted standards.

3.1 *SEMI Documents*

SEMI P1 — Specification for Hard Surface Photomask Substrates

SEMI P22 — Guideline for Photomask Defect Classification and Size Definition

4 Terminology

4.1 *Terms for General Description*

4.1.1 *halftone phase shift mask* — a photomask designed to increase resolution through intentional control of light transmittance and phase against a transparent part by replacing a conventional opaque pattern with a thin, partially transmitting film (halftone shifter film) that controls light phase difference and transmittance.

4.1.2 *phase shift mask* — a photomask designed to increase resolution through intentional control of the exposure light phase.

4.2 *Terms for Structural Description*

4.2.1 *additional film type opaque ring* — an opaque ring composed of light shield materials other than the shifter.

4.2.2 *embedded shifter type opaque ring* — an opaque ring composed of small rectangles or line/space patterns in a shifter.

4.2.3 *multilayer halftone phase shift mask* — a halftone phase shift mask having multiple thin films of different material compositions to give a certain phase difference and transmittance. The layer that adjoins the substrate should be called the first layer.

4.2.4 *opaque ring* — an area of a certain width, adjacent to the periphery of the desired exposure area on a reticle, located in the non-exposure area of the reticle to obtain a dark portion required in a wafer lithography process.

4.2.5 *single-layer halftone phase shift mask* — halftone phase shift mask having a thin film of uniform material composition to give a certain phase difference and transmittance.

4.3 *Terms for Description of Optical Characteristics*

4.3.1 *glass side reflectivity* — a ratio of intensity of reflected light to intensity of incident light into the glass side that is the backside of the shifter film. The intensity of incident light is usually calculated by the intensity of reflected light measured using a reference mirror. (Figure 1 illustrates the glass side reflectivity.)

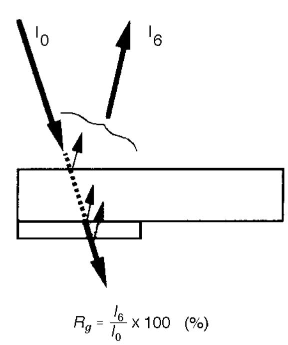

Figure 1
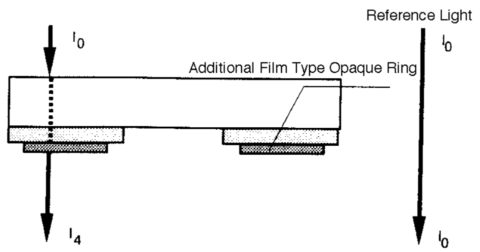
Glass Side Reflectivity

4.3.2 *opaque ring transmittance* — a ratio of intensity of light transmitted through the additional film type opaque ring area to intensity of incident light measured with air reference. (Figure 2 illustrates the opaque ring transmittance.)

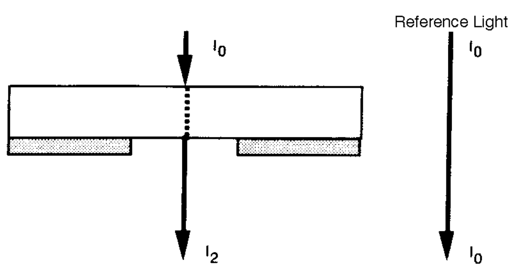
NOTE 1: For a halftone phase shift mask with embedded shifter type opaque ring, transmittance of the opaque ring area is not defined in this guideline because it depends heavily on the characteristics of the optical systems used.



$$T_4 = \frac{I_4}{I_0} \times 100 \quad (\%)$$

Figure 2
Opaque Ring Transmittance

4.3.3 *opening area transmittance* — a ratio of intensity of light transmitted through an opening area of a patterned halftone phase shift mask to intensity of vertical incident light measured with air reference. (Figure 3 illustrates the opening area transmittance.)

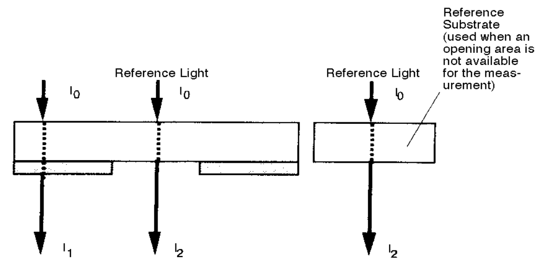


$$T_2 = \frac{I_2}{I_0} \times 100 \quad (\%)$$

Figure 3
Opening Area Transmittance

4.3.4 *phase difference* — a difference in phase of light generated by vertical transmission through a shifter area and an opening area with air equivalent to the shifter film in thickness.

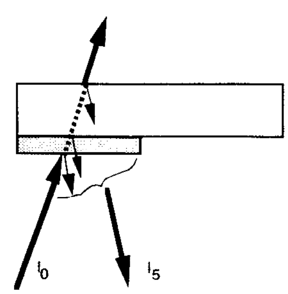
4.3.5 *relative transmittance* — a ratio of intensity of light transmitted through a shifter area to intensity of light transmitted through an opening area. (Figure 4 illustrates the relative transmittance.)



$$T_3 = \frac{T_1}{T_2} \times 100 \quad (\%) = \frac{\left(\frac{I_1}{I_0}\right)}{\left(\frac{I_2}{I_0}\right)} \times 100 = \frac{I_1}{I_2} \times 100 \quad (\%)$$

Figure 4
Relative Transmittance

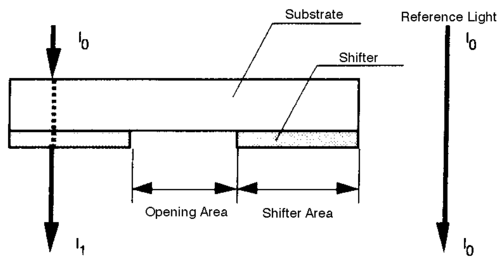
4.3.6 *shifter side reflectivity* — a ratio of intensity of reflected light to intensity of incident light onto the surface of a shifter film. The reflected light is the sum of the reflected light from the shifter surface and reflected light from the boundary between shifter and glass, and the boundary between glass and air. The reflectivity depends on the incident angle, the wavelength of the light, and the extent of polarization of the incident light. The intensity of incident light is usually calculated by the intensity of reflected light measured using reference mirror. (Figure 5 illustrates the shifter side reflectivity.)



$$R_s = \frac{I_5}{I_0} \times 100 \quad (\%)$$

Figure 5
Shifter Side Reflectivity

4.3.7 *shifter area transmittance* — ratio of intensity of light transmitted through a shifter area of a halftone phase shift mask (blank) to intensity of vertical incident light measured with air reference. (Figure 6 illustrates the shifter transmittance.)



$$T_1 = \frac{I_1}{I_0} \times 100 \quad (\%)$$

Figure 6
Shifter Area Transmittance

5 Mask Structure

5.1 Structure of a shifter shall be specified as single-layer type or multilayer type. A halftone shifter film whose components gradually change is classified into the multilayer type.

5.2 Structure of an opaque ring shall be specified as embedded shifter type or additional film type. In case of a mask blank, a light shield film may be added or not.

5.3 Addition of an electrically conductive layer, and/or a thin film for an etch-stop function shall be agreed upon by the supplier and user.

6 Film Thickness

6.1 For a mask blank, specifications such as film thickness of a shifter shall be agreed upon by the supplier and user. The film thickness may be described using a physical film thickness obtained from step height measurement, an optical film thickness obtained from ellipsometry or spectroscopy, and a controlled-film thickness obtained from rate method. Measuring method and measuring instrument shall be agreed upon by the supplier and user.

7 Film Materials

7.1 Specifications for materials and composition per layer in a shifter film and the opaque ring shall be agreed upon by the supplier and user.

8 Exposure Wavelength

8.1 As exposure wavelength, the center wavelength of g-line, i-line, KrF, ArF, and/or DUV shall be described in nm.

9 Transmittance

9.1 Specifications of transmittance shall be agreed upon by the supplier and user considering the selection of terms listed in Section 4.3 of this guideline.

9.2 A relative transmittance can also be obtained from the ratio of the shifter transmittance to the opening transmittance of a patterned halftone phase shift mask. In case the opening is not measurable, or it is a mask blank, a transmittance of a reference substrate should be used. The reference substrate shall be agreed upon by supplier and user beforehand.

9.3 Specifications of opening transmittance shall be agreed upon by the supplier and user considering its dependency to etching method.

9.4 Transmittance at the defect inspection wavelength, the dimension measurement wavelength, and/or the alignment wavelength shall be agreed upon by the supplier and user.

10 Phase Difference

10.1 Specifications of phase difference shall be agreed upon by the supplier and user giving attention to the measurement method. The unit should be degree. For a mask blank, the dependency of phase difference of a processed mask on the process method should be considered.

10.2 A measurement wavelength should be specified with its center value in nm. The measurement instrument and the bandwidth shall be agreed upon by the supplier and user.

11 Reflectivity

11.1 Shifter side reflectivity and glass side reflectivity should be described in percent, and its specification shall be agreed upon by the supplier and user. A measuring wavelength, a measuring instrument, a reference mirror, and an incident angle which are used for measurement shall be agreed upon by the supplier and user.

11.2 A defect inspection wavelength and an alignment wavelength shall be agreed upon by the supplier and user.

12 Opaque Ring Specification

12.1 Specification of an opaque ring shall be agreed upon by the supplier and user considering the type of opaque ring.

13 Etching Characteristics

13.1 Specifications of etching characteristics of a mask blank shall be agreed upon by the supplier and user.

14 Electrical Conductance

14.1 Electrical characteristics of a halftone phase shift mask blank should be represented by sheet resistance, and its specification and measuring method shall be agreed upon by the supplier and user.

15 Defects

15.1 Specific defects of a halftone phase shift mask and mask blank are phase defects and transmittance defects.

These defects are caused by halftone shifter dot, half-tone shifter hole, halftone shifter protrusion, halftone shifter intrusion, halftone shifter film thickness defect, halftone shifter film quality defect, and foreign materials.

15.2 Specifications for inspection and repair shall be agreed upon by the supplier and user.

15.3 Definition of defect sizes should conform to SEMI P22.

16 Ordering Information

16.1 It is recommended to agree mutually on the following items when ordering halftone phase shift masks. The other items should conform to SEMI P1.

Type of halftone structure	Single-layer type, or multilayer type
Type of opaque ring	Embedded shifter type, or additional film type
Film materials	To be agreed upon by the supplier and user
Exposure wavelength	To be agreed upon by the supplier and user
Transmittance	To be agreed upon by the supplier and user
Phase difference	To be agreed upon by the supplier and user
Reflectivity	To be agreed upon by the supplier and user
Defects, foreign materials, repair	To be agreed upon by the supplier and user

16.2 It is recommended to agree mutually on the following items when ordering halftone phase shift mask blanks. The other items should conform to SEMI P1.

Type of halftone structure	Single-layer type, or multilayer type
Light shield film	Added, or not
Film materials	To be agreed upon by the supplier and user
Exposure wavelength	To be agreed upon by the supplier and user
Transmittance	To be agreed upon by the supplier and user
Phase difference	To be agreed upon by the supplier and user
Reflectivity	To be agreed upon by the supplier and user
Etching characteristics	To be agreed upon by the supplier and user
Electrical conductivity	To be agreed upon by the supplier and user
Defects, foreign materials	To be agreed upon by the supplier and user

17 Sampling

17.1 Sampling should conform to SEMI P1.

PRACTICE FOR CATALOG PUBLICATION OF CRITICAL DIMENSION MEASUREMENT SCANNING ELECTRON MICROSCOPES (CD-SEM)

1 Purpose

1.1 The purpose of this practice is to define terms listed in critical dimension-scanning electron microscopes (CD-SEM).

1.2 This document is designed to create a common understanding between suppliers and users.

2 Scope

2.1 This practice applies to terms listed in the CD-SEM catalog.

2.2 This practice also applies to terms listed in the estimate and purchasing specification.

3 Referenced Documents

None.

4 Terminology

4.1 *accelerating voltage* — the mean kinetic energy of primary electrons converted into voltage.

4.2 *alignment* — corrects coordinates for positions and specimen stage. Matching the coordinates of a wafer and a specimen stage in order to address measured patterns formed on a wafer.

4.3 *alignment error* — distance from the pattern center to screen center after alignment. This is the maximum distance between the screen center and a target pattern after addressing by its coordinates and completing alignment.

4.4 *Critical Dimension Measurement SEM (CD-SEM)* — selects fine patterns on a wafer and measure dimensions. Here, wafers include SEMI standards (defined sizes) only. The operation is normally in the following "sequence": Transport -> Stage Travel -> Positioning -> Measuring -> Transport.

4.5 *magnification* — the ratio of a deflection width on a display to that on a measurement pattern. Compares the deflection width on the screen and on the pattern.

4.6 *permissible floor loading capability* — the minimum floor loading capability where the equipment can be settled.

4.7 *permissible floor vibration* — the maximum floor vibration that can provide the guaranteed resolution.

4.8 *permissible air vibration* — the maximum air vibration that can provide the guaranteed resolution.

4.9 *permissible stray magnetic field* — the maximum change in the stray magnetic field that can provide the guaranteed resolution.

4.10 *measurable range* — measurement range to guarantee static and dynamic repeatability as well as linearity. Measuring dimensions guaranteed to be within the specification of static repeatability, dynamic repeatability, and linearity.

4.11 *measurement pattern determination method* — identifies the pattern to be measured. This method is used to identify the pattern to be measured. It is performed by automatic pattern recognition, or instructions from the operator.

4.11.1 *automatic pattern determination method* — the pattern selection method based on the automatic pattern recognition system.

4.11.2 *manual pattern determination method* — operator uses cursors, etc. The pattern selection method is accomplished by the operator placing cursors on the measurement pattern.

4.12 *measurement precision*

4.12.1 *static repeatability* — variations in average measurement values acquired in a sequence for a pattern. This is the closeness of agreement between the measured values obtained by measuring a pattern with wafer loading, wafer alignment, stage traveling to a measurement site, positioning of a measured pattern, measuring, and wafer unloading.

4.12.2 *dynamic repeatability* — variations between the nominal and measured dimensions. This is the maximum dispersion of measurements from the best approximate line defined between the nominal and measured dimensions.

4.12.3 *reproducibility* — variations in average measurement values acquired in a sequence during a certain period. This is the closeness of agreement between the mean values obtained by measuring a pattern repeatedly at stated period with wafer loading, wafer alignment, stage traveling to a measurement site, positioning of a measured pattern, measuring, and wafer unloading.

4.12.4 *linearity* — variations in measurement values without changing device and wafer conditions. This is the closeness of agreement between the measured values obtained by measuring a pattern repeatedly without any changes of measurement conditions.

4.13 *measurement target* — kind of measurement pattern. The measurement pattern, such as line, space, pitch, hole, box-in-box, etc.

4.14 *stage positioning range* — range on a wafer that can be measured by moving the wafer. This is the measurable range of a measured wafer placed on a specimen stage with stage moving.

4.15 *operation method* — the control method of operation sequence. There are three methods: auto, semi-auto, and manual.

4.15.1 *automatic operation method* — the operation method controlled by a computer automatically, after an operator sets a carrier on the equipment. The computer follows the commands written in a recipe. Uses a recipe on a computer.

4.15.2 *manual operation* — the operation method controlled by an operator without a recipe. Uses an operator.

4.15.3 *semi-auto operation* — the operating method controlled by a computer and an operator. The operator confirms the results of each command in a recipe using an automatic operation. Uses a recipe with an operator.

4.16 *pattern edge determination method* — uses a computer or an operator to look at the image. This is the method for determining the edge position of a given pattern, which is calculated by computer algorithm or by operator instructions.

4.16.1 *automatic pattern edge determination* — there are several methods, such as the threshold method, the linear approximation method, and the curve fitting method. This is the method used to determine the edge position automatically by calculating from the line profile signal of the secondary or back-scattered electrons. The calculations are performed using the aforementioned three algorithms.

4.16.2 *manual pattern edge determination method* — the operator measures the distance between cursors per image edge area. This method is used to determine the edge position manually by calculation based on the width between cursors, which are set to the measurement pattern edges by operator.

4.17 *pattern positioning error* — distance from the center of screen after positioning. This is the maximum distance between the screen center and a target pattern after pattern positioning.

4.18 *positioning of measured patterns* — moving pattern to the center screen (center of image field).

4.19 *image resolution* — resolution between two points. This is the minimum resolving distance between any two points in an image.

4.20 *stage positioning error* — variations when moving stage to a selected location repeatedly without correction. This is the positioning error of stage, which occurs when traveling to the same site repeatedly without electron beam deflection.

4.21 *throughput* — the number of processed wafers (per unit time, which is calculated from the time required for processing under pre-scheduled measurement sequence and conditions).

4.22 *transport* — transferring wafer from a wafer carrier to a specimen stage, or the reverse process.

4.23 *wafer size* — wafer diameter.

5 Listed Items

The following are desirable items and examples for listing in the CD-SEM catalog.

5.1	Equipment name			
5.2	Model			
5.3	Performance			
5.3.1	Throughput	___________	wafers/h	(Example: 30 wafers/h)
5.3.2	Image resolution	___________	nm	(Example: 5 nm)
5.3.3	Measurement precision			
5.3.3.1	Static repeatability	___________	nm (3 σ_{n-1})	(Example: 5 nm (3 σ_{n-1}))
5.3.3.2	Dynamic repeatability	___________	nm (3 σ_{n-1})	(Example: 5 nm (3 σ_{n-1}))
5.3.3.3	Reproducibility	___________	nm (3 σ_{n-1})	(Example: 5 nm (3 σ_{n-1}))
5.3.3.4	Linearity	___________	nm (3 σ_{n-1})	(Example: 5 nm (3 σ_{n-1}))
5.3.3.5	Precision guaranteed range	___________ µm ~	___________ µm	(Example: 0.2 µm ~ 10 µm, 5,000 ~ 200,000 x)
5.4	Function			
5.4.1	Wafer transport/Stage system			
5.4.1.1	Transport method	___________	(Example: double cassette support to C to C method)	
5.4.1.2	Stage stopping error	___________	µm (Example: ± µm)	
5.4.1.3	Wafer size	___________	mm (Example: 100, 125, 150, 200 mm)	
5.4.1.4	Positioning range	___________	(Example: whole wafer surface)	
5.4.2	Alignment system			
5.4.2.1	Alignment method	___________	(Example: uses optical image)	
5.4.2.2	Alignment precision	___________	± µm (Example: µm)	
5.4.2.3	Pattern positioning method	___________	(Example: moving cursor)	
5.4.2.4	Pattern positioning precision	___________	(Example: ± 0.1 µm)	
5.4.3	Electro-optical system			
5.4.3.1	Electron gun type	___________	(Example: LaB6/schottky/C-FE)	
5.4.3.2	Accelerating voltage	___________	(Example: 0.5–1.5 kV, 0.1 kV step)	
5.4.3.3	Probe current	___________	(Example: 0.2–10 pA)	
5.4.3.4	Magnification	___________	(Example: 100 ~ 200,000 times)	
5.4.4	Measurement			
5.4.4.1	Measurement pattern	___________	(Example: line/hole/overlay)	
5.4.4.2	Pattern determination method	___________	(Example: automatic (pattern recognition)/manual/cursor)	
5.4.4.3	Pattern edge determination method	___________	(Example: automatic (line approximation)/threshold method)	
5.4.4.4	Operation method	___________	(Example: auto/semiauto/manual)	
5.4.4.5	Communication protocol	___________	(Example: SECS)	
5.4.5	Vacuum exhaust system	___________	(Example: TMP (500 L/s) 1 unit, SIP (20 L/s) 2 units)	
5.5	Installation conditions			
5.5.1	Dimensions	width______mm,	depth______mm,	height______mm (May be included in the standard diagram.)

6 Listed Items Guide (reference)

6.1 *Equipment Name* — List

6.2 *Model* — List

6.3 *Throughput* — To measure throughput, large-size wafers are generally used. List the number of processes per hour when 5-point measurement has been continuously processed. When wafers other than the maximum wafer sizes are used, list the wafer size. Also, list if the operator should intervene. The measurement position should be the center of wafer and the outside 4 points from 1/2 of the diameter on the diagonal line of the rectangle inscribing the wafer.

Please note that there are the following two methods:

6.3.1 The number of wafers that can be processed per hour for 1 wafer/lot processing.

6.3.2 The number of wafers that can be processed per hour for 25 wafers/lot continuous processing.

6.4 *Static Repeatability* — Use 3 σ_{n-1} and nm as the unit of measurement. When not listed, the sample should be the photoresist pattern and the number of measurement cycles should be 10.

6.5 *Dynamic Repeatability* — Use 3 σ_{n-1} and nm as the unit of measurement. When not listed, the sample should be the photoresist pattern, and the number of measurement cycles should be 10. In addition, one cycle of measurement should be just one cycle.

6.6 *Reproducibility* — Use 3 σ_{n-1} and nm as the unit of measurement. When not listed, the sample should be the photoresist pattern.

6.7 *Image Resolution* — The resolution should be listed in nm. In addition, the accelerating voltage acquired should be listed. When not listed, the sample should use gold deposition, and the conversion should be done from the photo image.

6.8 *Measurement Precision Warranty Range* — Should be listed in µm. When the precision depends on magnification, the listing of magnification is desirable.

6.9 *Operation Method* — List methods that can be used in auto, semi-auto, and manual.

6.10 *Transport Method* — List double-cassette supporting C to C method and/or SMIF supporting C to C method.

6.11 *Wafer Size* — List dimensions defined in SEMI M1. When creating guidelines, the dimensions are as follows: 2 inch, 3 inch, 100 mm, 125 mm, 150 mm, 200 mm, 300 mm, and 400 mm.

6.12 *Measurable Range* — List ranges that can be observed and measured through normal use in mm.

6.13 *Stage Stopping Error* — List the stopping error in mm when moving the maximum distance in both X and Y directions.

6.14 *Alignment Method* — List methods using optical microscopes, SEM images, and other.

6.15 *Alignment Precision* — List in µm.

6.16 *Measuring Pattern Identification Method* — List manual an auto and the content thereof.

6.17 *Pattern Edge Determination* — List manual an auto and the content thereof.

6.18 *Measuring Pattern Positioning Method* — List manual an auto and the content thereof.

6.19 *Measuring Pattern Positioning Accuracy* — List in µm.

6.20 *Magnification* — List range.

6.21 *Accelerating Voltage* — List range in V or kV units.

6.22 *Electron Gun* — List electron gun type.

6.23 *Vacuum Exhaust System* — List pump type, exhaust volume, and number of units.

6.24 *Communication Protocol* — List external computer and method of communication.

6.25 *Dimensions* — List block width, depth, and height per equipment block in mm. This may be listed in the standard layout diagram.

6.26 *Standard Layout Diagram* — List the standard layout when installing equipment. Equipment installation conditions can be listed in the diagram.

6.27 *Mass* — List in kg.

6.28 *Permissible Floor Weight* — List in kg/m^2.

6.29 *Permissible Stray Magnetic Field* — List in T, and list effective values or peak values separately.

6.30 *Permissible Floor Vibration* — List the maximum vibration level in dB in the 1~80 Hz frequency range. The vibration acceleration level La is found from the following equation:

$$La = 20\log(a/a_o)$$

Here,

a — Is the effective value of the vibration acceleration when the sensory vibration is not corrected:

a_o — (Standard vibration acceleration) (10^{-6} m/s^2)

6.31 *Permissible Air Vibration* — List the maximum sound level in dB in the 20 Hz ~ 8 kHz frequency range. The sound pressure level La is found from the following equation:

$La = 20\log(a/a_o)$

Here, a is the effective value for sound pressure in Pa units.

a_o (Standard sound pressure) (20 Pa)

6.32 *Reference Specification* — List guideline as the reference specification.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI P31-0997
PRACTICE FOR CATALOG PUBLICATION FOR CHEMICAL AMPLIFIED (CA) PHOTORESIST PARAMETER

1 Purpose

1.1 The purpose of this document is to provide a baseline for publication of chemical amplified (CA) photoresist parameters.

2 Scope

2.1 This document applies to CA photoresist used for semiconductor manufacturing.

2.2 This document is used as the guide to evaluate photoresist process parameters.

2.3 This document is not applicable for quality assurance.

3 Referenced Documents

None.

4 Terminology

4.1 *PEB* — post exposure bake

5 Description

NOTE: The following parameters for CA photoresist publication and test conditions should be described in the catalog.

5.1 Resist, overcoat and developer commercial name

5.2 Temperature and humidity

5.3 Environmental conditions (see Section 6)

5.4 Ammonia concentration measurement method (see Section 7)

5.5 Delay time dependency (see Section 8)

5.6 PEB temperature dependency (see Section 9)

5.7 PEB time dependency (see Section 10)

5.8 Substrate dependency (see Section 11)

5.9 *Measurement Conditions*

5.9.1 *Resist Coating and Development*

5.9.1.1 Resist baking method (contact baking or proximity baking)

5.9.1.2 Resist pre-baking temperature and time

5.9.1.3 Resist PEB temperature and time

5.9.1.4 Development time

5.9.1.5 Resist thickness

5.9.2 *Exposure*

5.9.2.1 Illumination conditions (NA, σ, etc.)

5.10 *Equipment Name*

5.10.1 Exposure equipment

5.10.2 SEM equipment

5.10.3 Ammonia concentration measurement equipment

6 Environmental Conditions

6.1 *Ammonia Concentration* — It is recommended to measure all CA photoresist parameters under the condition that the ammonia concentration is between 10–20 $\mu g/m^3$.

NOTE: CA photoresist is sensitive to the atmosphere, especially to ammonia. Acid from photoacid generator upon exposure is neutralized by the basic material in atmosphere like ammonia.

7 Ammonia Concentration Measurement Method

7.1 The ammonia concentration is measured by ion chromatography or another method which is capable to determine the ammonia concentration quantitatively in a range of 10–20 $\mu g/m^3$. The measurement equipment is calibrated with a standard ammonia solution.

8 Delay Time Dependency

NOTE: This section defines process conditions and procedures to obtain the delay time dependency.

8.1 *Resist Coating and Pre-baking* — Resist should be coated on the silicon substrate. After pre-baking, the resist thickness should be chose the bottom of swing curve of 0.7 μm. The actual thickness should be notified.

8.2 *Delay Time* — Delay time between resist coating and exposure, exposure and PEB, and PEB and development used for obtaining delay time dependency parameters are defined in Table 1.

Table 1 Delay Time Condition

Resist coating to exposure delay time						
0 min.			1 hour		6 hour	24 hour
NOTE: Normal sequential procedure without intentional delay between exposure and PEB as well as PEB and development.						
Exposure to PEB delay time						
0 min.	10 min.	30 min.	1 hour	2 hour		24 hour
NOTE: Normal sequential procedure without intentional delay between resist coating and exposure as well as PEB and development.						
PEB to development delay time						
0 min.	10 min.	30 min.	1 hour			24 hour
NOTE: Normal sequential procedure without intentional delay between resist coating and exposure time as well as exposure and PEB.						

NOTE: Zero minutes (0 min.) is defined as normal sequential procedure without intentional delay.

8.3 Measurement

8.3.1 After each time delay, fabricated 0.25 µm and 0.30 µm line and space patterns should be measured by SEM.

8.3.2 Record the measured pattern size.

8.3.3 Make the plotting of pattern size vs. delay time.

9 PEB Temperature Dependency

NOTE: This section defines process conditions and procedures to obtain the PEB temperature dependency.

9.1 *Resist Coating and Pre-baking* — Resist should be coated on the silicon substrate. After pre-baking, the resist thickness should be chose the bottom of the swing curve of 0.7 µm. The actual thickness should be notified.

9.2 *Measurement*

9.2.1 Ten points of temperature should be selected within ± 20 °C from the optimized PEB temperature. The fabricated 0.25 µm and 0.30 µm line and space patterns must be within the deviation of ± 20% from the optimized line width of 0.25 µm and 0.30 µm line and space patterns.

9.2.2 Record the measured pattern size.

9.2.3 Make the plotting of pattern width vs. PEB temperature. At least 6 to 8 points of pattern width should be plotted within the deviation of ± 10% from the optimized line width of 0.25 µm and 0.30 µm line and space patterns.

9.2.4 The cross section of resist patterns is observed and compared each other with standard sample. One should be selected from the optimized condition and the other one should be selected from the sample deviated around 10% from standard one.

10 PEB Time Dependency

NOTE: This section defines process conditions and procedures to obtain the PEB time dependency.

10.1 *Resist Coating and Pre-baking* — Resist should be coated on the silicon substrate. After pre-baking, the resist thickness should be chose the bottom of swing curve of 0.7 µm. The actual thickness should be notified.

10.2 *PEB Time* — PEB time should be selected from time 30 sec., 60 sec., 90 sec., 120 sec., 180 sec. on the optimized PEB temperature.

10.3 *Measurement*

10.3.1 Fabricated 0.25 µm and 0.30 µm line and space patterns should be measured by SEM.

10.3.2 Record the measured pattern size.

10.3.3 Make the plotting of pattern size vs. PEB time.

11 Substrate Dependency

11.1 *Resist Coating and Pre-baking* — Resist should be coated on a substrate. After pre-baking, the resist thickness should be chose the bottom of swing curve of 0.7 μm. The actual thickness should be notified.

11.2 *Observation* — Fabricated 0.25 μm and 0.30 μm line and space patterns and more than 1 μm isolated patterns should be observed by cross sectional SEM.

SEMI P32-0998
TEST METHOD FOR DETERMINATION OF TRACE METALS IN PHOTORESIST

1 Purpose

1.1 This document describes an outline of a quantitative analysis method on trace metal concentration. This standard is intended to promote communication between users and suppliers.

2 Scope

2.1 This document applies to a measurement of trace metal concentration in ppb level in photoresist by instrumental techniques, such as Atomic Absorption Spectrometry, Plasma Ion Source Mass Spectrometry, and Inductively Coupled Plasma Atomic Emission Spectrometry.

2.2 Object metals in this measurement are Al, Ca, Cr, Cu, Fe, Mg, Mn, Ni, K, and Na.

2.3 Either additional metals or fewer can be agreed upon between users and suppliers and are added to the measurement list.

2.4 The following method has given satisfactory results in determining trace metal impurities at the specified value for each of the target trace metals. Alternative methods or conditions may be used as long as appropriate studies demonstrate recovery between 75%–125% of a known sample spike for half the specification value. The results should be reported as within specification (below a certain value) or not in specification only (SEMI C1).

3 Referenced Documents

NOTE: As listed or revised, all documents cited shall be the latest publications of adopted standards.

3.1 *SEMI Standard*

SEMI C1 — Specifications for Reagents

3.2 *ASTM Standard*

ASTM D1193 — Standard Specification for Reagent Water

4 Summary of Method

4.1 Photoresist test solution is prepared by dry ashing method or direct method. Then trace metals in the test solution are measured by Atomic Absorption Spectrometry, Plasma Ion Source Mass Spectrometry, or Inductively Coupled Plasma Atomic Emission Spectrometry. The trace metal concentration is determined using a working curve, which is obtained by measuring a standard solution.

5 Terminology

5.1 *blank test* — a measurement without the subject photoresist, which is performed under the standard procedures.

5.2 *dilution factor* — numerical number that indicates final amount of solution divided by the initial amount of solution in the preparation of the photoresist process.

5.3 *direct method* — a sample preparation method for preparing samples for direct trace metal in photoresist. The materials are diluted with a solvent and then analyzed by the appropriate analytical instrument.

5.4 *dry ashing method* — a sample preparation method for preparing samples used in measuring trace metals in the photoresist. The photoresist is evaporated to dryness and decomposed to ash by heating. The ash is dissolved in a volumetric flask with acid and aqueous reagent, and then analyzed by the appropriate analytical instrument.

5.5 *plasma ion source mass spectrometry* — a method that isolates and measures quantitative metal element by mass spectrometer using plasma as excitation source. Inductively Coupled Plasma Mass Spectrometry (ICP-MS) and Microwave Induced Plasma Mass Spectrometry (MIP-MS) belong to this category.

5.6 *working curve* — the relationship between known metal concentrations prepared by standard solutions and the observed values of instrumental analysis.

6 Apparatus

6.1 *Measurement Equipment*

6.1.1 Flame Atomic Absorption Spectrometer (F-AAS) and ICP-MS can use the dry ashing method.

6.1.2 Graphite Furnace Atomic Absorption Spectrometer (GF-AAS), Electrothermal Atomization Atomic Absorption Spectrometer (ETA-AAS), ICP-MS, MIP-MS, and Inductively Coupled Plasma Atomic Emission Spectrometer (ICP-AES) can use the direct method.

6.1.3 *Instrument Condition* — Recommended instrumental conditions are summarized in Table 1 for each target metal.

Table 1 Measurement Equipment and Metal Elements

Element	*Atomic Absorption Spectroscopy*	*Plasma Ion Source Mass Spectrometry*		*ICP-Atomic Emission Spectrometer*
		ICP-MS (Note 1)	*MIP-MS (Note 2)*	
Al	309.2 nm	^{27}Al	^{27}Al	396.2 nm
Ca	422.7 nm	^{40}Ca ^{44}Ca (Note 3)	^{40}Ca	393.4 nm
Cr	357.9 nm, 359.4 nm	^{52}Cr ^{53}Cr (Note 3)	^{52}Cr	267.7 nm 283.6 nm
Cu	324.7 nm	^{63}Cu ^{65}Cu	^{63}Cu ^{65}Cu	324.8 nm
Fe	248.3 nm	^{56}Fe ^{54}Fe (Note 3)	^{56}Fe ^{54}Fe	259.9 nm
Mg	285.2 nm	^{24}Mg ^{25}Mg ^{26}Mg	^{24}Mg ^{25}Mg ^{26}Mg	279.6 nm
Mn	279.5 nm	^{55}Mn (Note 3)	^{55}Mn	257.6 nm
Ni	232.0 nm, 341.4 nm	^{58}Ni ^{60}Ni (Note 3)	^{58}Ni ^{60}Ni	221.6 nm, 231.6 nm
K	766.5 nm	^{39}K ^{41}K (Note 3)	^{39}K ^{41}K	766.5 nm
Na	589.0 nm	^{23}Na	^{23}Na	589.0 nm

NOTE 1: *ICP-MS* — Ar is used as the plasma generation gas.

NOTE 2: *MIP-MS* — N_2 is used as the plasma generation gas.

NOTE 3: Beware of interfering ion (see Table 2).

Table 2 Interfering Ions

Object Metal	*Interfering Ion*
^{39}K	$^{38}Ar^{1}H$
^{41}K	$^{40}Ar^{1}H$
^{40}Ca	^{40}Ar
^{52}Cr	$^{40}Ar^{12}C$ $^{36}Ar^{16}O$ $^{38}Ar^{14}N$
^{55}Mn	$^{40}Ar^{14}C^{1}H$ $^{40}Ar^{15}N$ $^{38}Ar^{16}O^{1}H$
^{56}Fe	$^{40}Ar^{16}O$ $^{38}Ar^{18}O$
^{58}Ni	$^{40}Ar^{18}O$

7 Vessels, Reagents, and Environment

7.1 *Vessel*

7.1.1 Quartz glass volumetric flask

7.1.2 Quartz glass measuring pipette

7.1.3 Quartz glass beaker

7.1.4 PTFE vessel

7.1.5 Platinum crucible

7.2 *Reagents*

7.2.1 *DI Water* — Resistivity ≥ 18.0 MΩ cm at 25°C per ASTM D 1193.

7.2.2 *Organic Reagent* — Use commercially guaranteed reagent for trace metal analysis. Use the reagent of the same production lot for all measurements.

7.2.3 *Inorganic Reagent* — Use commercially guaranteed reagent for trace metal analysis. Use the reagent of the same production lot for all measurements.

7.2.4 *Standard Reagent* — Use the commercially guaranteed reagents which have certified trace metals concentration.

7.3 *Environment*

7.3.1 The measurement is recommended to be performed in a clean room or clean zone at constant temperature. The stability of temperature should be better than ± 2°C. Dry ashing method should be performed in a draft chamber with HEPA filter, if possible.

7.3.2 In the case of volumetric analysis, the measurement environment is set to the standard temperature of measuring tools such as volumetric flask and measuring pipette.

7.3.3 Record the number of particles at different sizes at the measuring point, if possible.

8 Procedures

8.1 *Flow Chart of Measurement* — See Figure 1.

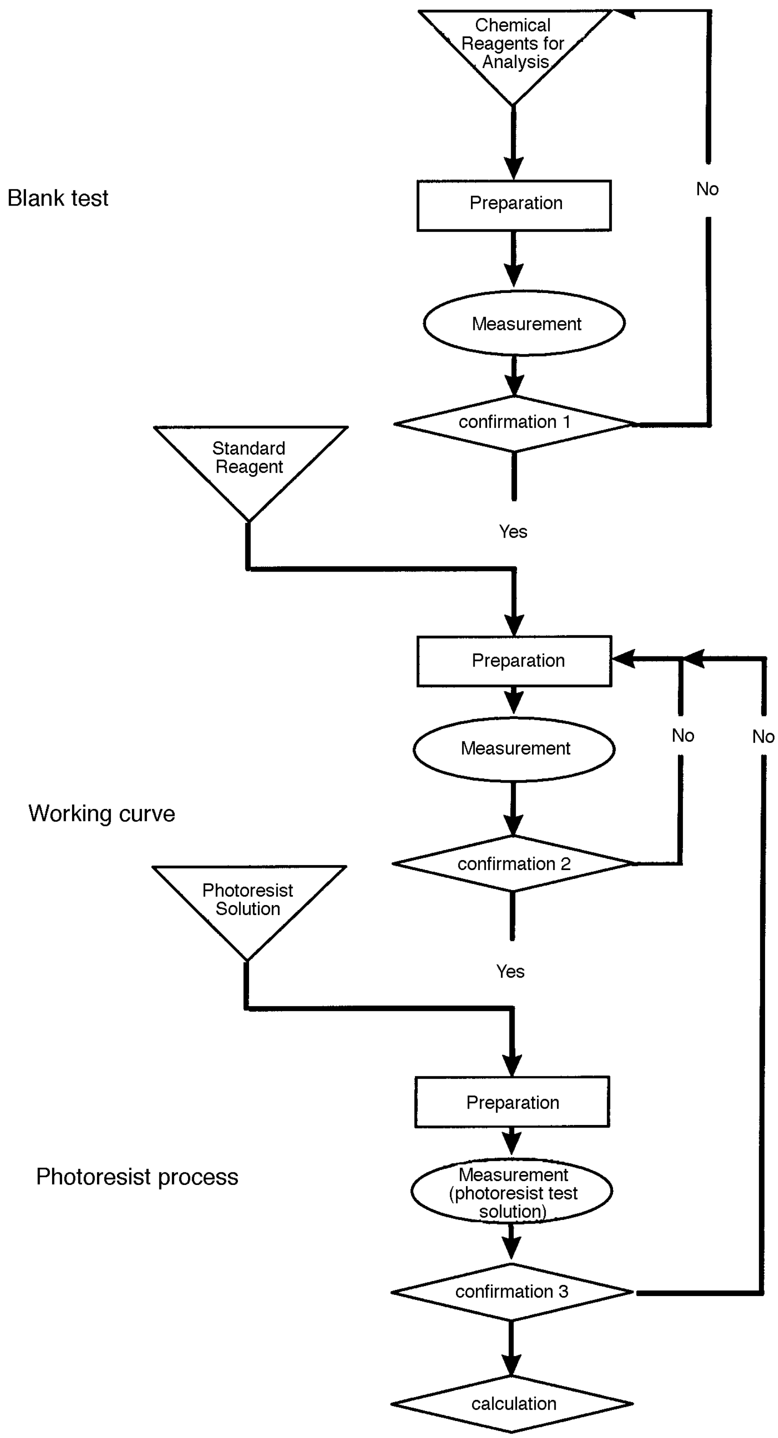

Figure 1
Flow Chart of Trace Metal Measurement

8.2 *Blank Test*

8.2.1 Prepare a blank test solution which is performed under the photoresist process without photoresist.

8.2.2 Measure each blank test solution for the same metals as measured in the photoresist.

8.2.3 The observed data should be adjusted for blank level and background corrections.

8.2.4 Determine the concentration of each metal element from the working curve (see Section 8.3).

8.2.5 *Confirmation 1* — Blank level should be equal or less than half the specification level in the photoresist.

8.3 *Working Curve*

8.3.1 The concentration range in the working curve should cover the anticipated concentration in photoresist test solution.

8.3.2 Prepare a standard solution with a known metal concentration using the reagents that are used in preparing the photoresist test solution. When checking for linearity (Section 8.3.6), more than three different concentrations should be used in preparing the standard curve.

8.3.3 Measure each metal element in the standard solution.

8.3.4 The observed data should be calibrated by the blank level correction and background correction.

8.3.5 Prepare a working curve for each metal element.

8.3.6 *Confirmation 2* — Working curve should be linear in the concentration range of standard solution.

8.4 *Measurement of Photoresist Test Solution*

8.4.1 *Dry Ashing Method*

8.4.1.1 Remove the solvent of photoresist by evaporation using Platinum crucible.

8.4.1.2 Ash the matrix by heating using Platinum crucible. Ashing temperature should be referred to Table 3. Resist cannot be ashed without possible loss of some elements, so loss of each element should be investigated before trace metal analysis.

Table 3 Recommended Ashing Temperature and Flame Component for F-AAS

Element	*Ashing Temperature (°C)*	*Flame Component*
Al	1000	N_2O-C_2H_2
Ca	800	Air-C_2H_2 N_2O-C_2H_2
Cr	800	Air-C_2H_2 N_2O-C_2H_2
Cu	800	Air-C_2H_2
F3 (NOTE 4)	600 300 (if $FeCl_3$ presents)	Air-C_2H_2 N_2O-C_2H_2
Mg	600	Air-C_2H_2 N_2O-C_2H_2
Mn	800	Air-C_2H_2 N_2O-C_2H_2
Ni	800	Air-C_2H_2
K (NOTE 5)	< 500	Air-C_2H_2 H_2-O_2
Na (NOTE 5)	< 500	Air-C_2H_2 H_2-O_2

NOTE 4: Iron can be present as ferric chloride and ferric chloride boils at 310°C.

NOTE 5: These elements tend to volatilize over 500°C.

8.4.1.3 Dissolve the ash in platinum crucible with acid.

8.4.1.4 Prepare a photoresist test solution in a volumetric flask with a constant volume of solvent.

8.4.1.5 In F-AAS analysis, analytical wavelength should be determined referring to Table 1. In ICP-MS analysis, analytical mass number should be determined referring to Table 1.

8.4.1.6 Measure each metal element in the photoresist test solution.

8.4.1.7 The observed data should be adjusted for blank level and background corrections.

8.4.1.8 Record the dilution factor, ashing temperature, acid, spike, and recovery for dry ashing. Record the analytical wavelength for F-AAS, or analytical atomic mass number for ICP-MS.

8.4.2 *Direct Method*

8.4.2.1 Prepare a photoresist test solution by diluting. Solvents such as PGMEA or EL are recommended.

8.4.2.2 Record the name of diluting solvent and dilution factor. Dilution factor is recommended to be in the range of 5 to 50.

8.4.2.3 In GF-AAS or ETA-AAS analysis, furnace program (step, temperature, lamp time, hold time) should be determined referring to Table 4 before trace metal analysis.

Table 4 Recommended Furnace Program for GF-AAS and ETA-AAS

Element	*Drying Temperature (°C)*	*Ashing Temperature (°C)*	*Atomization Temperature (°C)*
Al	130	1400	2700
Ca	130	1300	2600
Cr	130	1300	2700
Cu	130	900	1600
Fe	130	900	2500
Mg	130	900	2200
Mn	130	900	2600
Ni	130	1200	2700
K	130	800	2000
Na	130	800	2000

8.4.2.4 In GF-AAS, ETA-AAS, or ICP-AES analysis, analytical wavelength should be determined referring to Table 1. In ICP-MS or MIP-MS analysis, analytical mass number should be determined referring to Table 1.

8.4.2.5 Measure each metal element in the photoresist test solution.

8.4.2.6 The observed data should be calibrated by the blank level correction and background correction.

8.5 *Recommended Instrumental Conditions for Documentation*

8.5.1 Specify the equipment name.

8.5.2 Specify flame component and flow rate for F-AAS.

8.5.3 Specify carrier gas and flow rate for GF-AAS and ETA-AAS.

8.5.4 Specify plasma source gas and flow rate for ICP-MS, MIP-MS, and ICP-AES.

8.5.5 Specify furnace program (temperature for drying, ashing, atomization and cleaning, lamp time, hold time) for GF-AAS and ETA-AAS.

8.5.6 Specify analytical wavelength for F-AAS, GF-AAS, ETA-AAS, and ICP-AES.

8.5.7 Specify analytical atomic mass number for ICP-MS and MIP-MS.

8.6 *Concentration of Trace Metal in Photoresist*

8.6.1 The concentration of trace metal in a photoresist test solution is determined from the working curve. Determine the concentration of trace metal by multiplication of dilution factor to the observed concentration of a photoresist test solution. The unit of concentration should be represented in ppb.

8.6.2 The standard deviation should be calculated.

8.6.3 *Confirmation 3* — The observed concentration of photoresist test solution should be in the concentration range of working curve.

9 Suggested Reporting Information

9.1 Site

9.2 Test date

9.3 Company

9.4 Environment

9.4.1 Particle level

9.5 Sampling

9.5.1 Sample name (commercial name)

9.5.2 Lot No.

9.6 Results:

9.6.1 Element

9.6.2 Concentration (ppb)

9.6.3 Standard deviation 3 σ

9.6.4 Sample preparation method

9.6.4.1 Dry ashing method:

9.6.4.1.1 Ashing temperature

9.6.4.1.2 Dissolution acid

9.6.4.1.3 Dilution factor

9.6.4.2 Direct method:

9.6.4.2.1 Solvent name

9.6.4.2.2 Dilution factor

9.6.5 Measuring condition

9.6.5.1 Equipment name

9.6.5.2 Furnace program/temperature, lamp, and hold time for GF-AAS or ETA-AAS

9.6.5.3 Flame components and flow rate for F-AAS

9.6.5.4 Carrier gas and flow rate for GF-AAS or ETA-AAS

9.6.5.5 Plasma source gas for ICP-AES, ICP-MS, or MIP-MS

9.6.5.6 Analytical wavelength or analytical mass number

9.6.5.7 Blank level

9.6.5.8 Background correction

9.6.5.9 Correlation coefficient for working curve

PROVISIONAL SPECIFICATION FOR DEVELOPMENTAL 230 mm SQUARE HARD SURFACE PHOTOMASK SUBSTRATES

1 Purpose

1.1 To define the dimensional requirements for nominally square hard surface photomask substrates of 230 mm nominal edge length for research on, and development of, process and manufacturing equipment, pellicles, carriers, other accessory materials, and any related mask designs.

2 Scope

2.1 This specification covers information pertaining to glass substrates for 230 mm square hard surface photomasks. This information includes, but is not limited to, physical dimensions, testing criteria, and measurement criteria.

3 Referenced Documents

3.3 *Federal Standard*[3]

209E — Clean Room and Work Station Requirements, Controlled Environments

4 Terminology

4.1 *230 mm* — the nominal edge length for the reticle generation defined in this specification. Also referred to as "9 inch" size.

4.2 *critical side* — major side intended for patterning. The critical side has no chamfered corner(s) (see Section 9.2), and has flatness equal to or better than the non-critical side (see Section 8.1).

4.3 *non-critical side* — major side not intended for patterning. Any and all chamfered corners are on the non-critical side (see Section 9.2, Figures 5 and 6).

NOTE: Selected terms relating to photomasking are given for information only in Appendix 2, Related Information.

5 Ordering Information

5.1 Purchase orders for hard surface photomask substrates furnished to this specification shall include the following:

5.1.1 Nominal edge length, nominal thickness dimension, edge criteria, and parallelism of major sides (see Section 6);

5.1.2 Material (see Section 7);

5.1.3 Flatness quality area and flatness Total Indicated Reading (TIR; see Section 8);

5.1.4 Visual quality area (see Section 9); and

5.1.5 Lot acceptance criteria (see Section 10).

6 Dimensions and Permissible Variations

6.1 The substrates shall conform to the dimensional tolerances appropriate to the nominal edge length and thickness as listed in Table 1. Dimensions are illustrated in Figure 1, and a fixture for measuring the squareness dimensions is shown in Figure 2.

6.2 Substrates shall have beveled edges. The edges shall conform to the dimensional tolerances appropriate to the nominal thickness listed in Table 2. Dimensions are illustrated in Figure 3.

6.3 The major sides of square substrates shall be parallel within 5.0 µm along both major axes. Measurements are taken within the quality flatness area, along both major axes. Calculation of parallelism is illustrated in Figure 7.

7 Material Specifications

7.1 Substrate materials shall be specified "ultra low thermal expansion" (ULTE). An example of ULTE material is fused silica (quartz).

7.2 Selected physical properties of ULTE materials are provided for information only in Appendix 1.

8 Flatness Specifications

8.1 Substrates shall be supplied with two major sides having flatness (TIR) of 1, 2, or 5 µm over a square quality flatness area as defined in Figure 4. Sides are not required to have equivalent flatness. (NOTE: 0.5 µm is not yet available but is widely expected in the near future. Flatness of 0.5 µm is very desirable for semiconductor production, and equipment suppliers may want to consider this in their designs.)

9 Visual Criteria

9.1 A visual quality area, which may or may not correspond with the flatness area, shall be agreed upon between the user and supplier.

9.2 Fused silica (ULTE) substrates shall be identified with one corner chamfer as shown in Figure 5. Dimensions of the chamfer shall be as specified in Figure 6. The corner chamfer is made only on the non-critical side of the substrate.

10 Sampling

10.1 Unless otherwise specified, appropriate sample sizes shall be selected from each lot in accordance with ANSI/ASQC Z1.4. Each quality characteristic shall be assigned an acceptable quality level (AQL) in accordance with ANSI/ASQC Z1.4 definitions for critical, major, and minor classifications. If desired, and so specified in the contract or order, each of these classifications may alternatively be assigned cumulative AQL values. Inspection levels shall be agreed upon between user and supplier.

11 Test Methods

11.1 *Thermal Expansion* — Determine in accordance with ASTM E 228.

11.2 Flatness (to be agreed upon between user and supplier).

11.3 Visual (to be agreed upon between user and supplier).

11.4 Parallelism (to be agreed upon between user and supplier; non-contact methods are preferred).

12 Handling

12.1 Substrates are to be handled on the edges only. Substrates are to be handled with gloves approved for cleanroom use, when human handling is required.

13 Orientation

13.1 For ULTE substrates with a single corner chamfer (see Section 9.2), it is recommended that all orientation be performed referencing the corner of the substrate diagonally opposite the chamfer. See Figure 8 for more information.

14 Certification

14.1 Upon request of the purchaser in the contract or order, a manufacturer's or supplier's certification that the material was manufactured and tested in accordance with this specification, together with a report of the test results, shall be furnished at the time of shipment.

15 Packing and Marking

15.1 Substrates shall be packed in a class 100 environment as defined by Federal Standard 209. Containers shall be designed to prevent glass-to-glass contact, and to protect the substrates from contamination in handling and transit. Substrates shall be shipped with the critical side toward the front or bottom of the shipping carrier, depending on carrier configuration. The substrate shipping position shall be indicated on each container. Packaging shall comply with the applicable internal, national, state, and local laws and regulations required for shipping.

15.2 Containers shall be labeled "Warning: Open and Handle Under Cleanroom Conditions Only" as well as identified by user purchase order number (if applicable), drawing number (if applicable), quantity, supplier lot number, and material identification.

RELATED INFORMATION 1
TERMS AND DEFINITIONS

NOTE: This related information is not an official part of SEMI P33. The following terms and definitions are provided for information only. The Microlithography-related definitions identified herein were compiled from the Terminology sections of the Standards in the SEMI Microlithography Volume. The SEMI Microlithography Committee is currently updating all terminology through the Microlithography Terms and Definitions Task Force, and will eventually include the updated terminology in the SEMI Compilation of Terms.

SEMI makes no warranties or representations as to the suitability of the terms and definitions set forth herein for any particular application. The determination of the suitability of the terms and definitions is solely the responsibility of the user.

array rotation — the total array set rotated relative to substrate edges.

cavity — in pellicle technology, an unfilled space between the photomask and the optically transparent film within the mounted pellicle frame area.

coherence, spatial — the correlation of the electromagnetic fields at different points in space. Can be achieved with a non-monochromatic source.

coherence, temporal — the correlation of electromagnetic fields at different points in time but the same point in space (related to the non-monochromaticity of the source).

composite drawing — a large-scale drawing comprising all geometric forms required for a single device, arranged in proper relative positions. It is used as a guide for manual cutting by Rubylith, or for a digitizing guide for Computer Aided Design (see CAD). The set of colored overlay films made as work progresses to the reticle stage, can also be considered a composite, suitable for checking design errors. (SYN: Master Drawing, Engineering Drawing, Design Drawing.)

contact mask — in semiconductor fabrication, after the major diffusions, gates, and other active areas have been deposited, a glass insulating layer is placed over the whole die. Small holes are etched through this glass at points where the interconnecting metal conducts must ‘contact’ the active areas. The mask that defines these holes is characterized by many small squares (~0.2–0.4 mil) scattered throughout the die area.

contact printing — a process of reproducing an original by placing a photomask so that the coated side is in contact with the photoresist (or emulsion) surface of the area to be printed and then exposing the photoresist (or emulsion).

cure, photoresist — the process of eliminating undesirable properties of photoresists, such as tackiness, softness, the tendency to flow, lack of adhesion, etc.

dark area — an opaque area.

defect, gross photomask — a photomask defect that can be easily seen with the naked eye or under magnification no greater than 10×. Examples: large scratches, cracks in the glass substrate, drying marks, etc.

defect, photomask — any flaw or imperfection in the opaque coating or functional pattern of a photomask that will reproduce itself in a photoresist film to such a degree that it is pernicious to the proper functioning of the microelectronic device being fabricated.

degradation — reductions in image quality (measured as resolution, edge acuity, dimensional shifts, defect density, etc.) experienced in each generation of reproduction, as compared to the original or preceding generation. Generally, degradation increases with each generation, in a predictable manner.

diffraction pattern, spatial — intensity variations of light in the viewing plane caused by interference of waves undergoing diffraction.

element — a member of the set that makes up the photomask array; used either as a functional layer member for the fabrication of a single, integrated circuit or for test purposes. (Replaces chip, die, bar.)

emulsion — a suspension of a salt of silver in gelatin or collodion that is coated onto a photoplate and is exposed and developed to produce a photomask.

energy, minimum exposure — the energy corresponding to the total integrated energy of actinic radiation necessary to just completely render soluble a positive photoresist for a given replacement film thickness or just completely render insoluble a negative photoresist for a given single resist film thickness.

energy, optimum exposure — the energy per square centimeter corresponding to the total integrated energy of actinic radiation necessary to accurately reproduce photomask pattern dimensions in a photoresist of given thickness after exposure and development.

etch resistance — the ability of a photomask coating or protecting material, such as photoresist, in which the pattern is imaged or photoprinted.

etch time — the time required for the removal of a coating in an etching medium.

etchant — the chemically reactive solution used for removal of unwanted metallic coating from a substrate.

field — the background area of a device is defined as the area not being acted upon during the fabrication process. Thus, if a mask is to be used to produce metal interconnects, the area representing non-metal is the "field." The image polarity is named by the appearance of this field; thus, clear field, dark (opaque) field. This definition is very carefully stated because, in some devices, their gross appearance is very deceiving in that "field" cannot always be denoted as the major area. Some devices may have diffusion of buried layers, for instance, covering 80% of the area, the remaining 20% being the field. Some knowledge of the fabrication process is essential when determining field, as many of these ambiguous conditions exist where the field is less than 50% of the area. (ANT: active area; geometry; trace: diffusion area.)

film adhesive — adhesive between frame and film.

film thickness, dirt — fingerprint; mark touched by something; stain by liquid.

film thickness, particle — the particle state materials that can be distinguished from the film itself on the film surface or inside the film.

film thickness, pinhole — a small opening completely through a polymer film.

fixer — a chemical solution which makes an image permanent. In the case of silver emulsion processes, it dissolves and removes the unexposed/undeveloped silver halide crystals so that further darkening of the image cannot occur.

frame adhesive — adhesive between frame and photomask.

functional element — any contiguous fragment of a device that is necessary to the electrical operation of the finished device. Examples include diffused areas, traces, gates, contacts, etc.; excludes scribe lines, alignment marks, labels, etc. (SYN: active geometry.)

gel slug — a piece of clear, dried gelatin that has been trapped in a silver/gelatin emulsion during coating. A gel slug has the appearance, under a microscope, of a clear lens-like lump, generally 0.5 – 2 mils in size, and about twice as long as wide.

isolation layer — a partitioning, especially of bipolar devices, usually by diffusion, to electrically insulate functional components of an integrated circuit device. Isolation masks are usually layer 1 or 2, and characterized by thin lines defining open boxes all over the die area. (SYN: isolation mask.)

latent image — the invisible image formed on any photosensitive material after exposure. It requires some type of development to produce a useful, visible image.

layer — one of a sequential series of overlaying photomasks that make up a device series.

mask set — the complete series of masks for all layers, necessary to fabricate any given device.

master drawing — the original drawing from which the artwork is made.

master mask — original photomask, at 1× (final) scale, generated with a photorepeater from which submasters are printed. (SYN: master.)

matrix — the rectangular arrangement of die on a photomask. (SYN: array.)

mechanical strength — the physical condition a pellicle must meet to withstand a specified force from a blow-off gun without suffering any damage to the film.

mouse bite — see *mouse nip*.

mouse nip — in semiconductor imaging technology, a semicircular intrusion.

objective lens — in a microscope system, it is the lens closest to the test specimen (object). Usually provides the greatest amount of the total magnification and also limits system resolution. Most commonly several objectives, in typical powers of 10×, 20×, and 40×, are mounted on a turret for rapid magnification changes. See also *ocular*.

ocular — the set of microscope lenses closest to the observer's eye that produces final magnification of microscope. It usually contains graticules or filar-measuring apparatus. See also *objective lens*.

opacity — a direct measure of the light-stopping power of a semitransparent medium, as glass photographic emulsion or a thin chrome coating. Represented as the reciprocal of transmittance, O = 1/T. The common logarithm of opacity if used as Optical Density. $D = \text{Log}_{10}O$.

pellicle — a thin, optically transparent film, typically of nitrocellulose, attached to, supported by a frame, and attached to a photomask (or photomask reticle). NOTE: Its purpose is to seal out contaminants and reduce printed defects caused by contamination in the image plane of an optical exposure system.

photorepeater — a combination of a high-resolution reduction (usually 10× or 5×) camera and a programmable precision stage. The image from the camera is projected onto a photoplate, attached to the stage, and exposed in as many positions as required by moving the stage between exposures. The product of a photorepeater is the master mask. (SYN: image repeater; step-and-repeat camera.)

printing — the transfer of an image from one surface (substrate) onto another at 1× scale. Usually "printing" refers to the contact method, but it also can be accomplished using a 1-to-1 projection optical system. (SYN: contact printing.)

printing, contact — photoprinting photomask patterns by exposure of a photosensitive material coated on a supporting substrate to radiation passing through the photomask, which is in contact with the photosensitive material.

printing, off-contact — see *printing, proximity*.

printing, projection — a method of optically projecting an image onto a photosensitive material, thus eliminating the need for photomask/photosensitive-coating contact.

printing, proximity — photoprinting photomask patterns by exposure of photosensitive material coated on a supporting substrate to radiation passing through the photomask which is in the proximity of, but not in contact with, the photosensitive material being exposed.

reduction camera — a mechanism used to optically reduce the size of images and record them photographically. In two-step reduction, a copy camera is used for the range of 100× to 1000× reduced to 10×; the photorepeater reduces from 5× or 10× to 1×. Both are reduction cameras. See also *photorepeater.*

registration mark — a mark used to control placement of one layer relative to another.

repetitive defect — a defect (spot, pinhole, protrusion, or intrusion) introduced on the reticle so that in generating a master, it reproduces on every die.

reversal process — a photographic emulsion process that produces an image which is the same as the input image (i.e., clear areas remain clear, and opaque remain opaque). It is named 'reversal' because it yields the 'reverse' of the standard 'negative' process. Accomplished by developing the negative image, destroying this image by bleaching, and then subsequently developing all the original silver halide that represents the positive image. (SYN: positive-acting, process, positive process. ANT: negative acting process, normal process.)

rotation, of array — whole array is properly arranged (die relative to die), but placed on a blank which is rotationally mis-aligned. May occur during stepping or contact printing.

rotation, of die — on a master, misplacement of die by an angular displacement around the Z-axis. Usually caused by mispositioning of the reticle in a photorepeater so that it does not lie parallel to X- and Y-axis of stage travel.

run-in — a die placement error, where the die increment is less than the design dimension. This can occur during stepping, due to nonlinearity of miscalibration of the photorepeater stage scan scale, or during contact printing due to plate warpage.

shelf life — the period of time, at specified conditions of storage, in which the physical and chemical properties that affect a material's performance remain acceptable.

smear — a large area of partially removed coating or deposited foreign material.

space — area between image geometries; field between close-lying images. The space is often specified as the critical dimension. (SYN: field. ANT: digitized area; geometry.)

spinner — a device for holding a substrate and spinning it at a controlled rate of speed (usually 1000 to 6000 RPM), for applying extremely thin coating, as with photoresist.

submaster — a photomask printed in limited quantities from masters, and from which the working plates are printed. Used to reduce wear and tear on masters.

test device — a simplified, functional device (of the same process type as the majority die), inserted in several positions in any array, used for process control and monitoring during wafer fabrication.

torn image — image broken by movement of the image medium. Most often seen on emulsion images.

variable aperture — an aperture whose open area may be increased or decreased by movement of the elements forming the aperture.

visual defects — defects that can be identified by a skilled observer (with or without the aid of a microscope) without having to measure or compare (e.g., pinholes, slugs, spots, protrusions, etc.).

working plate — mask used selectively to expose photoresist on a wafer for IC fabrication. Usually printed from submasters or masters, thus preserving the master from excessive handling damage.

the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI P34-0200
SPECIFICATION FOR 230 mm SQUARE PHOTOMASK SUBSTRATES

This specification was technically approved by the Global Mask and Mask Equipment Committee and is the direct responsibility of the North American Microlithography Committee. Current edition approved by the North American Regional Standards Committee on September 3, 1999. Initially available at www.semi.org November 1999; to be published February 2000.

1 Purpose

1.1 To define the standard requirements for nominally square photomask substrates of 230 mm nominal edge length.

2 Scope

2.1 This specification covers information pertaining to substrates for 230 mm square photomasks. This information includes, but is not limited to, physical dimensions, material properties, and testing and measurement criteria.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Referenced Standards

3.1 *ANSI Standard*[1]

ANSI/ASQC Z1.4 — Sampling Procedures and Tables for Inspection by Attributes

3.2 *ASTM Standard*[2]

ASTM E228 — Standard Test Method For Linear Thermal Expansion of Solid Materials With a Vitreous Silica Dilatometer

3.3 *ISO Standard*[3]

ISO 14644-1 — Cleanrooms and associated controlled environments

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

4 Terminology

4.1 *230 mm* — the nominal edge length for the reticle generation defined in this specification. Also referred to as “9 inch” size.

4.2 *corner chamfer* — the bevel found in one corner of the substrate, in excess of the edge chamfer, as defined in Section 9.3 and Figure 6.

4.3 *critical side* — major side intended for patterning. The critical side has no chamfered corner(s) (see Section 9.3), and has flatness requirement equal or better than the non-critical side (see Section 8.1).

4.4 *edge chamfer* — the bevel found on all intersections between major and minor sides, as defined in Section 6.2 and Figure 3.

4.5 *non-critical side* — major side not intended for patterning. Any and all chamfered corners are on the non-critical side (see Section 9.3 and Figures 5 and 6).

5 Ordering Information

5.1 Purchase orders for photomask substrates furnished to this specification shall include the following:

5.1.1 Nominal edge length, nominal thickness, edge criteria including straightness and squareness, and parallelism of major sides (see Section 6); straightness shall be measured on all four minor sides;

5.1.2 Material (see Section 7);

5.1.3 Flatness quality area and flatness Total Indicated Reading (T.I.R.; see Section 8);

5.1.4 Visual quality area and defect limits (see Section 9); and

5.1.5 Lot acceptance criteria (see Section 10).

6 Dimensions and Permissible Variations

6.1 The substrates shall conform to the dimensional tolerances appropriate to the nominal edge length and thickness as listed in Table 1. Dimensions are illustrated in Figure 1 and a fixture for measuring the squareness dimensions is shown in Figure 2.

6.2 Substrates shall have chamfered edges between major and minor sides, and rounded corners between minor sides. The edges shall conform to the dimensional tolerances appropriate to the nominal thickness listed in Table 2. Dimensions are illustrated in Figure 3.

6.3 The major sides of substrates shall be parallel within 5.0 μm along both major axes. Measurements

1 American National Standards Institute, 11 West 42nd Street, 13th Floor, New York, NY 10036

2 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, PA 19428-2959

3 ISO Central Secretariat, 1, rue de Varembé, Case postale 56, CH-1211 Genève 20, Switzerland

are taken within the flatness quality area, along both major axes. Calculation of parallelism is illustrated in Figure 7.

7 Material Specifications

7.1 Substrate material shall be specified as fused silica (quartz). Fused silica is considered to be ultra low thermal expansion (ULTE) class material.

7.2 Substrate materials shall conform to thermal expansion and optical transmittance tolerances specified in Table 3.

7.3 Selected physical properties of fused silica are provided for information only in Appendix 1.

8 Flatness Specifications

8.1 Substrates shall be supplied with two major sides having a flatness (T.I.R.) of 1, 2, or 5 µm over a flatness quality area as defined in Figure 4a or Figure 4b. Sides are not required to have equivalent flatness.

NOTE 2: Flatness of 0.5 µm is very desirable for semiconductor production, and equipment suppliers may want to consider this in their designs.

9 Visual Criteria

9.1 A visual quality area, which may or may not correspond with the flatness quality area, shall be agreed upon between the user and supplier.

9.2 Each substrate shall not have more defects than listed in Table 4. This table includes limits for the following types of defects:

9.2.1 Internal defects in the visual quality area,

9.2.2 Critical side surface defects in the visual quality area,

9.2.3 Non-critical side surface defects in the visual quality area, and

9.2.4 Defects outside the visual quality area.

9.3 Fused silica substrates shall be identified with one corner chamfer as shown in Figure 5. Dimensions of the chamfer shall be as specified in Figure 6. The corner chamfer is made only on the non-critical side of the substrate.

NOTE 3: This configuration of corner chamfers is different than the configuration used for smaller ULTE class material substrates as defined in SEMI P1.

10 Sampling

10.1 Unless otherwise specified, appropriate sample sizes shall be selected from each lot in accordance with ANSI/ASQC Z1.4. Each quality characteristic shall be assigned an acceptable quality level (AQL) in accordance with ANSI/ASQC Z1.4 definitions for critical, major, and minor classifications. If desired, and so specified in the contract or order, each of these classifications may alternatively be assigned cumulative AQL values. Inspection levels shall be agreed upon between user and supplier.

11 Test Methods

11.1 Thermal Expansion — Determine in accordance with ASTM E228.

11.2 Transmission (to be agreed upon between user and supplier).

11.3 Flatness (to be agreed upon between user and supplier).

11.4 Visual (to be agreed upon between user and supplier).

11.5 Parallelism (to be agreed upon between user and supplier; non-contact methods are preferred).

12 Handling

12.1 Substrates are to be handled on the edges only. When human handling is required, substrates are to be handled with gloves approved for cleanroom use.

13 Orientation

13.1 For fused silica substrates with a single corner chamfer (see Section 9.3), it is recommended that all orientation be performed referencing the corner of the non-critical side diagonally opposite the corner chamfer. The corner for orientation signifies two orientation edges for positioning of the substrate. One edge shall be used for rotation baseline by two points. The other edge shall be used for positioning by one point. See Figure 8 for more information.

14 Certification

14.1 Upon request of the purchaser in the contract or order, a manufacturer’s or supplier’s certification that the material was manufactured and tested in accordance with this specification, together with a report of the test results, shall be furnished at the time of shipment.

15 Packing and Marking

15.1 Substrates shall be packed in a class 5 environment as defined by ISO 14644. Carriers shall be designed to prevent substrate-to-substrate contact, and to protect the substrates from contamination in handling and transit. Substrates shall be shipped with the critical side toward the front or bottom of the shipping carrier, depending on carrier configuration. The substrate shipping position shall be indicated on each carrier. Packaging shall comply with the applicable international, national, state, and local laws and regulations required for shipping.

15.2 Containers shall be labeled "Warning: Open and Handle Under Cleanroom Conditions Only" as well as identified by user purchase order number (if applicable), drawing number (if applicable), quantity, supplier lot number, and material identification.

Index of Refraction @ λ = 193 nm	1.5608
Thermal Optical Coefficient @ λ = 436 nm	10.6 ppm/°C @ 22°C
Thermal Optical Coefficient @ λ = 365 nm	11.2 ppm/°C @ 22°C
Thermal Optical Coefficient @ λ = 248 nm	14.2 ppm/°C @ 22°C
Thermal Optical Coefficient @ λ = 193 nm	20.6 ppm/°C @ 22°C

NOTE 1: Thermal Optical Coefficient is the same as Temperature Coefficient of Index of Refraction.

SEMI P35-0200^E
TERMINOLOGY FOR MICROLITHOGRAPHY METROLOGY

This terminology was technically approved by the Global Metrology Committee and is the direct responsibility of the North American Microlithography Committee. Current edition approved by the North American Regional Standards Committee on December 15, 1999. Initially available at www.semi.org January 2000; to be published February 2000.

E This document was editorially modified in March 2000. Changes were made to Sections 5.2.3, 5.4, 5.9, and the footnotes.

1 Purpose

1.1 Clear and commonly accepted definitions are needed for efficient communication and to prevent misunderstanding between buyers and vendors of metrology equipment. The purpose of this document is to provide a consistent terminology for the study and discussion of metrology issues important to microlithography.

2 Scope

2.1 The scope of this document is limited to the definitions of metrology terms used in microlithography. Every attempt is made to keep these definitions consistent with relevant international standards and common usage. This document is not intended to describe a measurement procedure, but an approach to defining a measurand in a useful and unambiguous way.

2.2 This document will grow as more terms are added in future revisions.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Referenced Standards

3.1 *SEMI Standards*

SEMI P28 — Specification for Overlay-Metrology Test Patterns for Integrated-Circuit Manufacture

3.2 *ANSI/NCSL Standards*[1]

Z540-2 — US Guide to the Expression of Uncertainty in Measurement, ANSI/NCSL standard (the US version of Guide to the expression of uncertainty in measurement, ISO, 1995, 110 p., ISBN 92-67-10188-9)

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

4 Some Metrology Issues

4.1 *Measuring Linewidth* — Any measurement of length or position contains an unknown error whose influence on subsequent application of the measurement data is best described by the measurement uncertainty (reference Section 3.2). The problem of measuring feature size on photomasks or integrated circuit wafers (*e.g.*, linewidth) is complicated by the fact that a feature is a 3-dimensional object whose exact shape is generally not known. The metrology problem is further complicated when the object is microscopic and only its magnified image can be measured.

4.2 Feature measurement data are usually reduced to one or a few parameters because the additional data needed to describe the complex feature shape are seldom available and may be immaterial to the subsequent application of the measurement data.

4.3 The first rule of metrology is to define exactly what is to be measured. The approach used here, in light of the previous paragraphs, is to construct a simple idealized geometric shape, or model (Figure 1), which approximates a real object of complex shape. The model, whose size and center position are well defined, is substituted for the real feature in application of the measurement data. A model can be refined to better approximate the actual feature shape by adding degrees of freedom, requiring more parameters to describe the measurement. For example, a line might be represented by a rectangular cross section (with width and height) or better represented by a trapezoidal cross section (with base width, height, and two wall angles). The differences between the model and the actual shape of the feature contribute to the overall measurement uncertainty of the size or position of that feature.

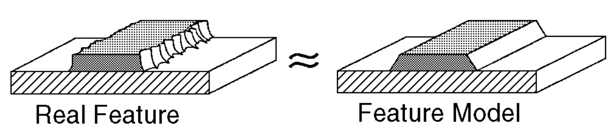

Figure 1
The Feature Model Approximates the Size and Shape of the Feature

1 American National Standards Institute, 11 West 42nd Street, 13th Floor, New York, NY 10036, website: www.ansi.org

5 Definitions

Defined terms appearing in the definitions of other terms are *italicized*.

5.1 *bounding box* — a user-specified *feature model* with a planar face lying in the *reference plane* and with user-specified orientation in the *reference plane*, intended to represent the position and size of the *feature*. See Figure 2 for an example. The bounding box need not be rectangular.

5.1.1 *outer bounding box* — smallest *bounding box* encompassing the *feature*.

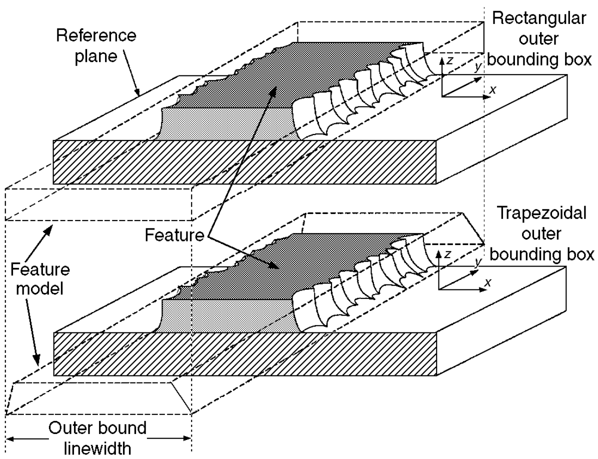

Figure 2
Two Possible Bounding Box Choices for a Line Feature

5.1.2 *best fit bounding box* — *bounding box* best fitting the *feature*, with user-defined criteria of best fit.

5.2 *feature (lithographic)* — region within a single continuous boundary, and attached to a *reference plane*, that has a physical property (parameter) that is distinct from the region outside the boundary. (Adapted from SEMI P28.)

NOTE 2: In general a feature is a 3-dimensional object, but some features can be adequately modeled as 2-dimensional objects.

5.2.1 *feature boundary* — surface defined by a user-specified property, such as a threshold, maximum gradient, *etc*., of the parameter distinguishing the *feature* from its surroundings. Open *features*, such as vias or spaces between lines, may be bounded in height by an additional plane parallel to the *reference plane*.

5.2.2 *feature height* — dimension of the specified *bounding box* perpendicular to the *reference plane*.

5.2.3 *feature model* — a solid geometrical shape, with well defined parameters: length, width, height, centroid, etc. (Figure 1), meant to approximate the actual shape of a *feature boundary*.

NOTE 3: A rectangular solid is often used to represent a line; a different extruded polygon may better represent the shape of the line. A hemisphere may best represent a solder bump. The more complex the model, more degrees of freedom are available to better fit the model to the feature, and more dimensional parameters are needed to describe the feature's size.

5.2.4 *feature placement* — coordinates describing the position of the centroid of the specified *bounding box* projected onto the *reference plane* relative to a coordinate system in that plane.

5.2.5 *feature size* — dimensions of the specified *bounding box*.

5.2.6 *nominal feature size* — the intended or specified dimension of a *feature*.

5.3 *linewidth* — (*a*) width of a specified rectangular *bounding box* constrained to the line *height* and bounding a specified line segment. Additional constraints, such as orientation parallel to the length direction, may be placed on the *bounding box*; (*b*) appropriate parameters describing the width of a different bounding box.

NOTE 4: Linewidth is sometimes referred to as critical dimension or CD.

5.3.1 *best fit linewidth* — width of constrained *best fit bounding box*.

5.3.2 *inner bound linewidth* — largest linewidth *bounding box* entirely inside the line segment.

5.3.3 *outer bound linewidth* — smallest linewidth *bounding box* encompassing the line segment.

5.3.4 *section linewidth* — width of the planar rectangle defining the intersection of a linewidth *bounding box* and a plane parallel to and a specified distance from the *reference plane*. See Section 5.3 (*b*).

5.4 *measurand* — particular quantity subject to measurement (reference Section 6.1).

5.5 *measurement uncertainty* — parameter, associated with the result of a measurement, that characterizes the dispersion of the values that could reasonably be attributed to the *measurand*. Numerically, it is a stated factor chosen to represent the desired confidence interval (usually 2 for 95% or 3 for 99%) times the square root of the sum of the variances of the probability distributions of all the possible errors (both random and systematic), as described in *ANSI/NCSL Z540-2-1997* (reference Section 3.2).

5.6 *overlay* — vector distance between the *feature placements* of two corresponding *features* created at different processing levels, in the *reference plane* coordinate system.

5.7 *pattern* — set of one or more *features*.

5.7.1 *pattern placement* — coordinates describing the centroid of the set of *features* comprising the *pattern* in the *reference plane* relative to a coordinate system in that plane.

5.8 *reference plane* — in the context of this document, a user-defined plane approximating the surface of a substrate and containing a coordinate system.

NOTE 5: All dimensional measurement data are referred to the reference plane coordinate system.

5.9 *traceability* — property of the result of a measurement or the value of a standard whereby it can be related to stated references, usually national or international standards, through an unbroken chain of comparisons all having stated *uncertainties* (reference Section 6.1).

SEMI P36-0600
GUIDELINE OF MAGNIFICATION REFERENCE FOR CRITICAL DIMENSION MEASUREMENT SCANNING ELECTRON MICROSCOPES (CD-SEMS)

This guideline was technically approved by the Global Metrology Committee and is the direct responsibility of the Japanese Metrology Committee. Current edition approved by the Japanese Regional Standards Committee on March 1, 2000. Initially available at www.semi.org May 2000; to be published June 2000.

1 Purpose

1.1 The purpose of this guideline is (1) to define common and important specifications of magnification references which are used for calibrating magnifications of critical dimension measurement scanning electron microscopes (CD-SEMs), and as the result (2) to provide magnification references which are easy for anyone to use.

2 Scope

2.1 It is preferable that design, manufacture and purchase specifications for CD-SEM magnification references conform to this guideline.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Referenced Standards

3.1 None.

4 Terminology

4.1 *CD-SEM magnification reference* — a CD-SEM magnification reference is defined as a standard for calibrating magnifications of a said CD-SEM through mounting the standard on the specimen stage, measuring the dimensions of reference patterns formed on the standard, determining the difference between the measurement value and the true or reference value of the reference patterns, and adjusting the CD-SEM parameters to bring the difference zero.

4.1.1 There are two types of CD-SEM magnification references: one is a wafer on which reference patterns are formed; another is a chip on which reference patterns are formed. Hereinafter, the former will be referred to as “wafer-type magnification reference,” and the latter will be referred to as “chip-type magnification reference.”

4.2 *edge roughness* — Edge roughness refers to edge variations seen in the SEM images, and is defined as the distance, within a field of view, between the peak line and the valley line, where the peak line means the line which runs through the highest peak and is parallel to the pattern-edge mean line, the valley line means the line which runs through the lowest valley and is parallel to the pattern-edge mean line, and the pattern-edge mean line conforms to the expected pattern-edge line. Here, a peak is the tip of a convex section, and a valley is the deepest part of a concave section (See Figure 1).

5 Ordering Information

5.1 Specify whether a said CD-SEM magnification reference is a wafer-type magnification reference or a chip-type magnification reference.

6 Requirements

6.1 *CD-SEM Magnification References and Their Structure*

6.1.1 CD-SEM Magnification References are either wafer type or chip type. Chip types are composed of a chip (or chips) and a stub to hold the chip (or chips). Wafer type include a 'drop-in' wafer which is a wafer with a thinned section where a die with the reference calibration pattern can be dropped in.

6.2 *Shape, Size and Mounting Method of CD-SEM Magnification References*

6.2.1 Shape and size of wafer-type magnification references, and method of mounting them on the specimen stages in CD-SEMs must follow the shape, size and mounting method of product wafers.

6.2.2 Shape and size of chip-type magnification references, and method of mounting them on the specimen stages of CD-SEMs are defined as follows:

6.2.2.1 Size and shape of chip-type magnification references: See Figure 2.

6.2.2.2 Mounting method of chip-type magnification references:

6.2.2.2.1 A magnification reference should be mounted on a specimen stage as markers made on the stub fit in markers made on the specimen stage, and be fixed by using a screw. The markers made on the stub should show the direction of reference patterns at an accuracy of within ± 1°.

6.2.2.2.2 The markers made on the specimen stage should show the X- and Y-direction of specimen-stage movement, and the angle between the two markers should be 90° ± 0.1° (See Figures 2 and 3).

6.2.2.3 Chip surface height for chip-type magnification references:

6.2.2.3.1 The height of chip surface (or reference pattern surface) from the specimen stage surface should be 1.7 ± 0.05 mm as the magnification reference is mounted on the specimen stage.

6.3 *Materials for Magnification References* — Materials for magnification references must be non-magnetic and conductive.

6.3.1 Wafers for wafer-type magnification references and chips for chip-type magnification references are preferable to be silicon.

6.3.2 Materials of the stub for chip-type magnification references are preferable to be aluminum, copper, or carbon.

6.4 *Properties of Magnification Reference Pattern*

6.4.1 Reference patterns do not change or degrade in use.

6.4.2 The block area of reference patterns (or every block area, in the case where there are some reference pattern blocks) must be larger than 100 µm × 100 µm, and the block should be placed so that it is easily recognizable.

6.4.3 The pattern-edge roughness must be within the calibration uncertainty described in Section 6.5.5.

6.5 *Report*

6.5.1 Suppliers of CD-SEM magnification references must report the following to the purchaser.

6.5.2 Wafer material for wafer-type magnification references, or chip and stub materials for chip-type magnification references: e.g., silicon chip, aluminum stub, etc.

6.5.3 Type of reference patterns: e.g., dense lines, etc.

6.5.4 Figures and/or pictures of the reference patterns with pattern dimensions which show top and/or cross sectional view.

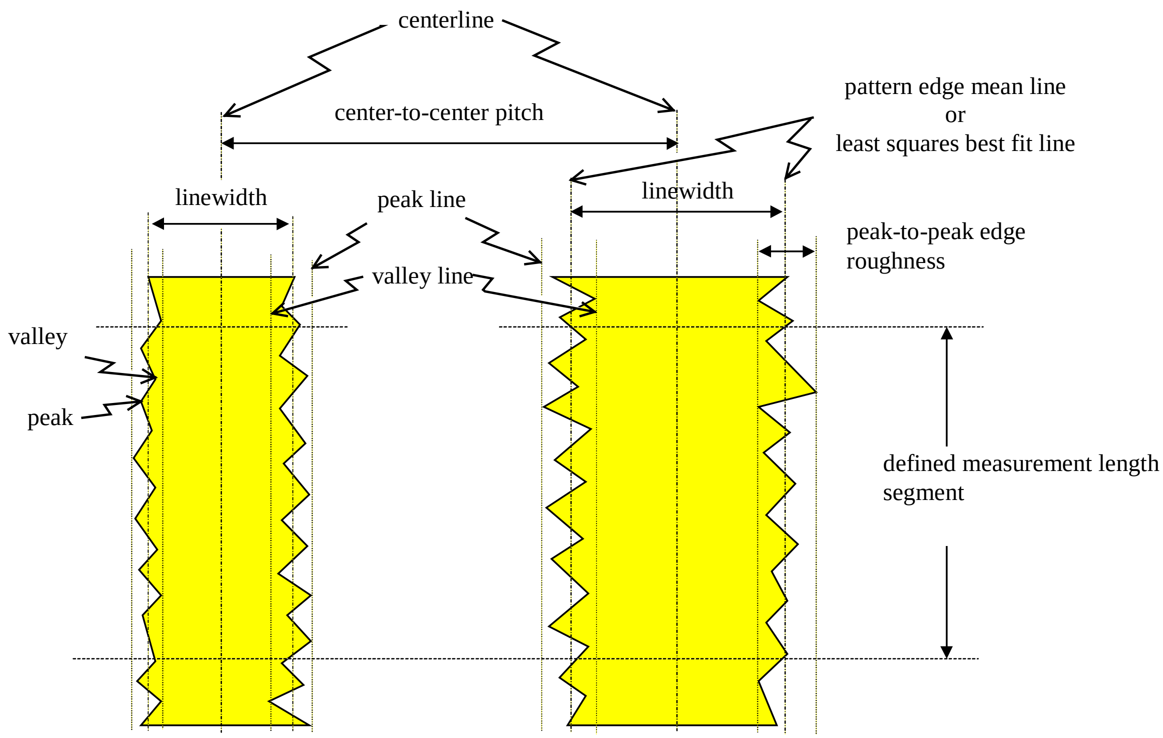
6.5.5 Calibration uncertainty of reference patterns: e.g., line pitch 180 ± 1 nm at 95% confidence level, etc.

6.5.6 Traceability and its certification organization, and measurement method used for deciding the calibration uncertainty of reference patterns: e.g., the uncertainty was decided in terms of mean value and variation obtained by means of a precise diffraction angle measurement using a He-Cd laser beam of a 2 mm spot diameter, and was certified by NMI (National Metrology Institute), etc.

NOTE 1: Traceability is the property of the calibration of the reference patterns whereby it can be related to stated references, usually national or international standards, through an unbroken chain of comparison of all having stated uncertainties. Refer to the international vocabulary of basic and general items in metrology, ISO, 1993, 60 p., ISEN 92-67 01075-1.

6.5.7 Applicable magnification range: e.g., 50k×–200k×, etc.

6.5.8 Notices of caution for cleaning and maintenance: e.g., whether cleaning is possible or not, and if possible, the process of cleaning, procedures for storage, etc.



NOTE 1: The figure ignores that fact that the SEM image is gray-scale and not black and white. Use the same intensity threshold setting for measuring pitch as for line width The center-to-center pitch averaged over the measurement length segment is to be certified and used for SEM magnification calibration

APPENDIX 1
NOTES

NOTE: The material in this appendix is an official part of SEMI P36 and was approved by full letter ballot procedures on March 1, 2000 by the Japanese Regional Standards Committee.

A1-1 Reference patterns for adjusting CD-SEM magnification using their pitches and reference patterns for optimizing pattern-edge determination parameters using their widths

A1-2 The following procedures are generally applied to critical dimension measurements using CD-SEMs: an electron beam linearly scans across the measured pattern, secondary and/or reflected electrons emitted from every electron-beam incident point are collected to form its intensity profile, pattern edges are determined on the intensity profile using a designated pattern-edge determination method, and the measurement value of the width of the pattern is obtained from the distance between the two pattern edges.

A1-3 Therefore, measurement errors of CD-SEM measurements can be partitioned into two components: one is magnification error and another is pattern-edge determination error. Magnification error is caused by variation of the equipment conditions such as the sampling pitch and incident angle of electron beam. Pattern-edge determination error is affected by the manner of measurement such as pattern-edge determination algorithm used and pattern-edge determination parameters used, and the properties of the specimen such as pattern topography (e.g., pattern-edge slope) and pattern material.

A1-4 Magnification error, including inter-machine magnification error, can be detected and corrected through measuring pitches of reference patterns, and pattern-edge determination error could be detected and corrected through measuring widths of the reference patterns practical reference patterns are available for measuring their widths. However, it seems extremely difficult to produce practical reference patterns for measuring their widths; the source of the problem lies in the physics of electron beam image formation and not because the reference patterns are somehow inadequate because of the following reasons: (a) reference pattern can not be determined uniquely, since intensity profiles obtained are different from each other dependent on pattern topography and pattern materials even if the width of every reference pattern is the same, (b) it is technologically difficult to solve the problem of width change due to the contamination which changes the measurement value of pattern width dependent on measurement time.

SEMI P37-1101
SPECIFICATION FOR EXTREME ULTRAVIOLET LITHOGRAPHY MASK SUBSTRATES

This specification was technically approved by the Global Micropatterning Committee and is the direct responsibility of the North American Micropatterning Committee. Current edition approved by the North American Regional Standards Committee on August 27, 2001. Initially available at www.semi.org September 2001; to be published November 2001.

1 Purpose

1.1 This specification covers the general requirements of the substrate for Extreme Ultraviolet Lithography (EUVL) masks.

2 Scope

2.1 This standard details the physical characteristics required for EUVL mask substrates. The specific material is not specified to allow for innovation in materials and substrates.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Referenced Standards

3.1 *ISO Standard*[1]

ISO 14644-1 — Cleanrooms and Associated Controlled Environments Part 1: Classification of Air Cleanliness

3.2 *ANSI Standard*[2]

ANSI/ASQC-Z1.4 — Sampling Procedures and Tables for Inspection by Attributes.

NOTE 1: Unless otherwise indicated, all documents cited shall be the latest published versions.

4 Terminology

4.1 None.

5 Ordering Information

5.1 Purchase orders for EUVL mask substrates furnished to this specification shall include the following:

5.1.1 Material coefficient of thermal expansion (see Section 7);

5.1.2 Defect quality area dimensions and defect limits (see Section 9); and

5.1.3 Lot acceptance criteria (see Section 10).

6 Dimensions and Permissible Variations

6.1 The square substrates shall conform to the dimensional tolerances appropriate to the nominal edge length and thickness as listed in Table 1. Dimensions are illustrated in Figure 1.

6.2 Substrates shall have chamfered or rounded edges. The edges shall conform to the dimensional tolerances appropriate to the nominal thickness listed in Table 2. Dimensions are illustrated in Figure 1.

6.3 Substrates shall be identified with notches at three corners on the backside of the substrate as shown in Figure 1. Dimensions of notches shall be as defined in Figure 1.

6.4 Figure 2 shows three datum points on the edges of the mask substrate. Three datum points are also shown on the back surface of the mask substrate. These datum points serve as reference locations for all dimensional measurements listed in Table 1.

7 Material Specifications

7.1 Substrate materials shall be identified as near zero thermal expansion (NZTE). Examples of NZTE materials are titania doped silica glass or two phase glass ceramics.

7.2 Substrate materials shall conform to thermal expansion characteristics defined in Table 3 over the entire range of temperature listed and at all spatial points within the substrate.

7.2.1 The thermal expansion properties of the substrate are defined in four classes. The particular class of thermal expansion material used shall be agreed upon between user and supplier. The thermal expansion properties of the substrate are defined over the entire temperature range shown in Table 3.

---

1 International Organization for Standardization, ISO Central Secretariat, 1, rue de Varembé, Case postale 56, CH-1211 Geneva 20, Switzerland. Telephone: 41.22.749.01.11; Fax: 41.22.733.34.30 Website: www.iso.ch

2 American Society for Quality Control, 611 East Wisconsin Avenue, Milwaukee, WI 53202, USA

7.2.2 Table 3 defines the permissible range of the mean and the permissible range of the coefficient of thermal expansion.

7.3 The substrate material shall have specific stiffness as defined in Table 3.

7.4 Selected physical properties of NZTE materials are provided for information only in Appendix 1.

7.5 The front, sides, and or back surfaces of the substrate may be coated with layers that are agreed upon between user and supplier. The substrate including these optional additional layers must meet all requirements outlined in this standard.

8 Flatness Specifications

8.1 Substrates shall be supplied with front and back sides having flatness as listed in Table 4 over a flatness quality area as defined in Figure 3. The flatness error is defined as the deviation of the surface from the plane that minimizes the maximum deviation, which is illustrated in Figure 4.

8.2 The global flatness requirement for the front and back sides, which includes the region excluded from the flatness quality area (defined in Figure 3), is shown in Table 4.

8.3 Substrates shall be supplied with wedge angle defined in Table 4 and defined in Figure 5.

8.4 Substrates shall be supplied with local slope angle as defined in Table 4 and defined in Figure 4.

8.5 A low order thickness variation (LOTV) requirement is defined over a range of spatial periods (shown in Table 4) composing the surface profile power spectral density. This thickness variation may be determined from the residual flatness error of the front and back surfaces after removing the wedge angle from the data.

8.6 The surface roughness requirements for the front and backside are listed in Table 4, and they are defined over a range of spatial periods.

9 Visual Criteria

9.1 A defect quality area, which may or may not correspond with the flatness area, shall be agreed upon between the user and supplier. Figure 6 shows the labeling of the dimensions of the defect quality area.

9.2 Each plate shall not have more defects than listed in Table 5 inside the defect quality area defined in Figure 6 on the front side. Dimensions of the quality area shall be agreed upon between user and supplier. Each plate shall not have more defects than listed in Table 5 outside the defect quality area defined in Figure 6 on the front side.

9.3 Each plate shall not have more defects than listed in Table 5 on the back side within the flatness quality area defined in Figure 3.

10 Sampling

10.1 Unless otherwise specified, appropriate sample sizes shall be selected from each lot in accordance with ASQC-Z1.4. Each quality characteristic shall be assigned an acceptable quality level (AQL) in accordance with ASQC-Z1.4 definitions for critical, major, and minor classifications. If desired, and so specified in the contract or order, each of these classifications may alternatively be assigned cumulative AQL values. Inspection levels shall be agreed upon between user and supplier.

11 Test Methods

11.1 *Thermal Expansion* — to be agreed upon between user and supplier.

11.2 *Flatness and Wedge Angle* — to be agreed upon between user and supplier.

11.3 *Visual* — to be agreed upon between user and supplier.

11.4 *Surface Roughness* — to be agreed upon between user and supplier.

12 Certification

12.1 Upon request of the purchaser in the contract or order, a manufacturer's or supplier's certification that the material was manufactured and tested in accordance with this specification, together with a report of the test results, shall be furnished at the time of shipment.

13 Packing and Marking

13.1 Substrates shall be packed in a class 1 environment as defined by ISO 14644-1. Containers shall be designed to protect the substrates from contamination in handling and transit. Substrates shall be shipped with the acceptable flatness side toward the front of the box. This orientation shall be indicated on each container. Packaging shall comply with the applicable internal, national, state, and local laws and regulations required for shipping.

13.2 Containers shall be labeled “Warning: Open and Handle Under Cleanroom Conditions Only” as well as identified by user purchase order number (if applicable), drawing number (if applicable), quantity, supplier lot number, and material identification.

Poisson's Ratio	ν	0.17–0.25
Index of refraction	n	1.4–1.6
Electrical conductivity at 20°C	σ (Siemens/m)	10^{-14}–10^{-18}
Dielectric constant	ε at 1 KHz	3.5–9.0

SEMI PR7-0302
PROPOSED PHOTOMASK QUALIFICATION TERMINOLOGY

This proposed terminology was technically approved by the Global Micropatterning Committee and is the direct responsibility of the European Micropatterning Committee. Current edition approved by the European Regional Standards Committee on December 20, 2001. Initially available at www.semi.org January 2002; to be published March 2002.

1 Purpose

1.1 This standard is aiming to define a unique language in the field of specification for, and qualification of, photomasks for use in optical lithography within the semiconductor industry.

2 Scope

2.1 At present only the International Technology Roadmap for Semiconductors (ITRS) serves as a universally accepted working document how to specify photomasks, however the definitions used are subject to interpretation. Different tool makers, mask makers and mask users are hindered in the communication with each other, as they first need to know and understand each others terminology. The lack of a common terminology complicates comparison of tools. A uniformly used, and universally accepted terminology, with a minimum of ambiguity, is required.

2.2 The definitions listed are for mask qualification, incorporating 3 possible types of value for a given qualification parameter:

- *<(true) qualification parameter>*, which would be the result of an ideal measurement of the total population of features of interest[1].
- *<measured qualification parameter>*, the result of a given population of measurements. It is hereby mentioned that a measured value (for example the mean, the standard deviation, the range) is always subject to the sample size of the measured population and the measurement method. Therefore both the sample size and the measurement method are mandatory information.
- *<qualification parameter spec(ification)>*, the maximum or minimum value that may not be exceeded for the selected population of measurements which must be defined as mandatory information.

2.2.1 The first two types of value for a given parameter will be defined in the present document.

2.2.2 The third parameter type will not be discussed here, since it is an upper limit to the measured qualification factor, and subject to the agreement between the individual parties of the mask qualification process.

2.3 *Restricted Scope For The First Version* — The present version of the document is restricted to the consideration of one-dimensional qualification in the mask pattern plane, i.e. parameters related to width measurement.

2.4 To assist users, the major differences in recommended default values between this standard and the ITRS mask table definitions are noted where applicable.

2.5 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety health practices and determine the applicability or regulatory limitations prior to use.

3 Limitations

3.1 The definitions listed are specific to state-of-the-art photomasks, with a focus on reduction reticles. They may therefore overrule any related terminology in other standards, with a more general scope. Application to other type of masks, e.g. for next generation lithography, may be feasible, but is NOT intended to be within the scope of the present document.

SEMI Compilation of Terms

1 See reference document in Section 4.2.

4.2 *ISO Standards* [2]

International Vocabulary of Basic and General Terms in Metrology

4.3 *International Technology Roadmap for Semiconductors (ITRS)* [3]

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Interpretation of Related General Terminology

NOTE 2: This paragraph includes general terms, as a basis for the specific mask related terminology, which is the main subject of this document.

5.1 *feature* — as defined in SEMI P35.

5.2 *proximity range* — distance over which a feature influences another significantly (criterion to be stated). It applies to mask fabrication, mask metrology and/or printed wafer image, defining 3 types of proximity range (terminology for example *mask fabrication proximity range*). It is mandatory to state which of the 3 is referred to.

NOTE 3: Further in this document *proximity range* will refer by DEFAULT to the first type mentioned.

5.3 *line* — a clear field, dark feature of semi-infinite length (>> *proximity range*) determined by its width (called a 1D feature, see Figure 1). Such feature may also be called a line when it is shorter, insofar its length:width ratio is larger than 2 (called a 2D feature, as the width may be affected by the feature-ends)

5.4 *space* — in analogy to line, but dark field, clear feature (see Figure 1).

5.5 *contact* — a dark field, clear feature with length:width ratio ranging from 0.5 (1 is default) to 2 maximum (see Figure 1). The width of such feature may be measured 1D-wise, but for enhanced relevance it requires 2D or, more specifically, area assessment. A large contact can be called a *window*.

5.6 *dot* — in analogy to contact, but clear field, dark feature (see Figure 1). A large dot can be called a *pad*.

5.7 *isolated feature* — feature that has no neighbors within a distance smaller than the proximity range.

5.8 *dense features* — features that influence each other (all that are not isolated). Clarification is required to describe the proximity, either by detailing the feature pitch and number of lines, for regular arrays (pitch = design values of line width and space width added), or by describing the surrounding area (see Section 7). In absence of such clarification dense is regarded by default as equal lines and spaces (or “half pitch” in general) in a semi-infinite array size, insofar that the feature width does not exceed the proximity range.

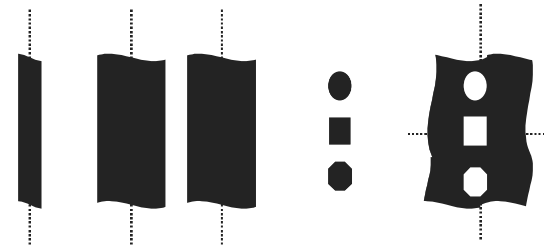

Figure 1
Nomenclature feature types (as designed)
Default contact (dot) is square.

6 Coordinate System

6.1 The coordinate system XYZ for this document is defined in Figure 2. It is defined with patterned mask side upwards and mask orientation as it was patterned. XY determines the mask plane. Z is the direction perpendicular to it. z = 0 for the absorber–substrate interface and z < 0 to the substrate side. Absorber is for example chrome or embedded material.

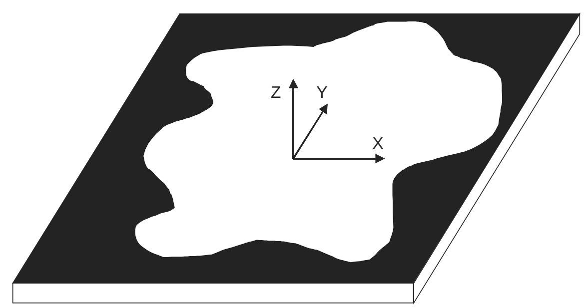

Figure 2
Mask coordinate system

6.2 Features are called vertical when their length is along Y. Feature width is then measured in X. This corresponds to Figure 2 of SEMI P35. Horizontal features have their length along X. Feature width is then measured in Y. See Figure 3.

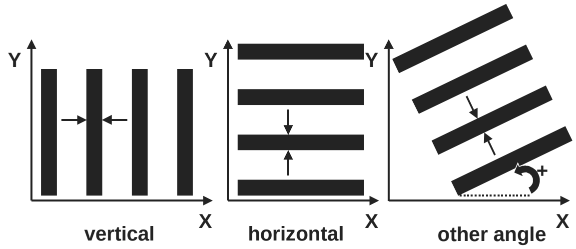

Figure 3
Orientation of Mask Features

7 Mask Qualification Terminology

7.1 *feature width* — Width of a cross section of a mask feature at a certain height defined by an appropriate bounding box model as described in SEMI P35, to be mentioned (see Figure 4). DEFAULT is at z = 0.

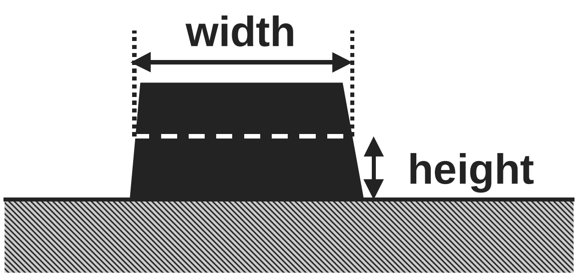

Figure 4
Cross section of a mask feature

7.2 *measured feature width* — Width determined from the measured signal obtained on the mask feature. For example width determined at a certain level of the signal.

To be stated as mandatory information:

- region of interest. For 1D features this corresponds to the specified line segment (SEMI P35),
- measurement method used (SEM, optical reflection, optical transmission, AFM, …),
- calibration and/or correlation used, and
- precision (SEMI P24).

and as optional information:

- measurement tool, and
- measurement algorithm used.

NOTE 4: The bounding box could be infinitely short as in the special situation of a measurement of a feature using a cross-section.

7.3 *feature edge* — Position of the material boundary of a mask feature at a certain height of the physical cross section (see Figure 2 of SEMI P35), to be stated as mandatory information. DEFAULT is feature/substrate interface.

7.4 *measured feature edge* — Position determined from the measured signal obtained on the mask feature edge. For example position determined at a certain level of the signal, as defined by the bounding box model of SEMI P35. Same mandatory/optional information must be stated as for *measured feature width.*

7.5 *critical dimension (abbreviated to CD)* — A user defined feature width of interest, mainly used for further qualification. Can be plural. DEFAULT is one width and one pitch. Mandatory information is width. (see *feature width uniformity*)

NOTE 5: The ITRS mask table assumes multiple pitches.

7.6 *feature width uniformity* — The spread of the distribution of the width of all mask features of a given design size selected as detailed hereafter. To be stated as mandatory information:

- its targeted feature width,
- all type and tone of features considered (line, contact, space, …as defined in SEMI P19),

  NOTE 6: Several could be combined, but the recommendation is one tone and one type, DEFAULT is lines for clearfield, spaces for darkfield.

- all orientations considered (adopting a pre-determined mask orientation), for example horizontal and vertical together, horizontal only, vertical only, including other angles, horizontal-and-vertical separately, …DEFAULT is horizontal and vertical together,
- the pitch of the feature (or in general: a description of the surrounding area, see further), e.g. equal lines and spaces, isolated line, …, or (if wished, but not recommended) an interval of pitches, and

  NOTE 7: In the latter case the defined feature width uniformity would not be proximity free. DEFAULT is one fixed pitch, to be mentioned. (The ITRS mask table assumes multiple pitches.)

- The considered area of interest on the mask.

7.7 *measured feature width uniformity* — Measured value of *feature width uniformity*, stating as mandatory information in addition to that of *measured feature width*:

- the number of measurement points used,
- the criterion used (range, 3-sigma, maximum deviation, ..), where sigma stands for standard deviation. Recommendation: Before 3-sigma is relevant, the distribution needs to be “normal” or

"near normal", and the number of measurements should be > 30, and

- the measured area on the mask.

and as optional information:

- the spatial distribution of measurement locations. DEFAULT is spread evenly over the measurement area.

7.8 *(measured) CD uniformity* is the special case of *feature width uniformity* where the selected feature is the *critical dimension*.

7.9 *mean-to-target* — The difference between the mean width of features, selected as detailed, and the targeted feature width, stating the same information as for *feature width uniformity*. (DEFAULT: selecting the same values as for *feature width uniformity*)

7.10 *measured mean-to-target* — The difference between the mean of measured feature widths and the targeted feature width, stating the same information as for *feature width uniformity* and in *measured feature width uniformity* (DEFAULT: selecting the same values as selected therein)

7.11 *(measured) CD mean-to-target* is the special case of *mean-to-target* where the selected feature is the *critical dimension*.

7.12 *maximum feature width deviation from target* — Maximum deviation from target in the total population of features considered, stating the same information as in *feature width uniformity*. (DEFAULT: selecting the same values as used therein)

7.13 *measured maximum feature width deviation from target* — Maximum deviation from target in the population of measurements, stating the same information as in *feature width uniformity* and in *measured feature width uniformity.* (DEFAULT: selecting the same values as used therein)

NOTE 8: (measured) maximum feature width deviation from target combines (measured) feature width uniformity and (measured) mean-to-target.

7.14 *mean X-Y deviation* — The difference between the mean of considered feature widths in X and Y directions (horizontal and vertical direction), stating the same information as *feature width uniformity*. (DEFAULT: selecting the same values)

7.15 *measured mean X-Y deviation* — The difference between the mean values of measured feature widths in X and Y directions, stating the same information as for *feature width uniformity* and in *measured feature width uniformity* (DEFAULT: selecting the same values as used therein)

7.16 *X-Y deviation uniformity* — The spread of the distribution of the difference between the width of all considered feature widths in X and Y directions (horizontal and vertical direction), stating the same information as *feature width uniformity*.

7.17 *measured X-Y deviation uniformity* — The spread of the distribution of the difference between the width of the measured feature widths in X and Y directions (horizontal and vertical direction), including/stating the same information as *feature width uniformity* and in *measured feature width uniformity*.

7.18 *feature linearity error* — Range of the deviations between the mask feature width and the respective target width on a range of feature widths, stating as mandatory information:

- the range of feature widths used (at mask level) (DEFAULT is the interval from the critical dimension to 5 times this).

  NOTE 9: The ITRS uses a wider interval.

- all type and tone of features considered, e.g. line, contact, space, …(see Section 5). It is a strong recommendation to fix on 1 tone/ 1 type to reach a useful number. DEFAULT is on lines ("*line linearity error*"). Contacts may be more challenging *("contact linearity error*"),

- all orientations considered, e.g. horizontal and vertical together, horizontal only, vertical only, including other angles, horizontal-and-vertical separately, …(see Figure 5)

- the pitch of the feature (or in general: a description of the surround(ing mask area), see further), e.g. equal lines and spaces, isolated line, …, or (if wished, but not recommended) an interval of pitches. DEFAULT is isolated features only, which is defined as *feature intra-proximity error.*

  NOTE 10: If a range of pitches is included, the resulting definition will include (inter)proximity effects. (The ITRS mask table assumes multiple pitches.)

7.19 *measured feature linearity error* — Measured value of *feature linearity error*, stating as mandatory information in addition to that of *measured feature width*:

- the number of measurement points used per feature width (which is recommended > 1. Then the mean value for each feature width is used).

and as optional information:

- the quality area, and
- the spatial distribution of measurement locations.

7.20 *feature inter-proximity error* — Range of the deviations between the mask feature width of a given size and the respective target width, on a variation of local pattern density and configuration (= of surround), stating as mandatory info:

- The nominal feature width at mask level,
- all type and tone of features considered, e.g. line, contact, space..(see Section 5). It is a strong recommendation to fix on 1 tone/ 1 type to reach a useful number. DEFAULT is on lines (*line inter-proximity error),*
- all orientations considered, e.g. horizontal and vertical together, horizontal only, vertical only, including other angles, horizontal-and-vertical separately, …
- range of feature pitches. DEFAULT is equal lines-and-spaces to isolated features. If only lines-and-spaces and isolated features themselves (and nothing in-between) also *iso-dense deviation* can be used, and
- In more general cases an alternative detailed description of the surround(ing mask area), preferably clarified with a drawing, will replace the pitch information.

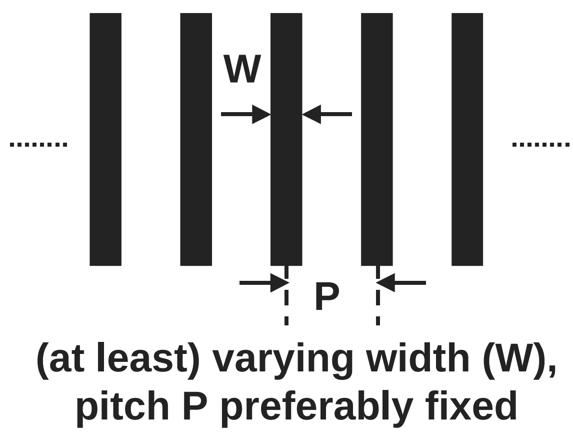

Figure 5
Feature Linearity

7.21 *measured feature inter-proximity error* — Measured value of *feature inter-proximity error*, stating as mandatory information in addition to that of *measured feature width*:

- the number of measurement points used per pitch or surrounding mask area (recommendation is > 1. Then the mean value is used).

and as optional information:

- the measured area on the mask, and
- the spatial distribution of measurement locations.

7.22 *feature proximity error* — Range of the deviations between the mask feature width and the respective target width on a range of feature widths and on a variation of local pattern density and configuration (= of surround), stating as mandatory info: … (to be adopted from linearity and inter-proximity)

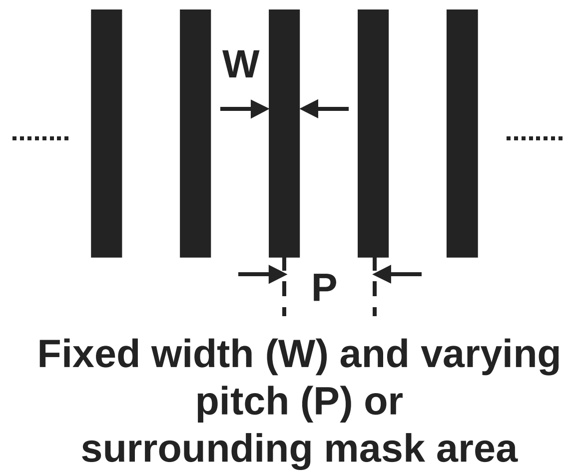

Figure 6
Feature Inter-proximity

7.23 *measured feature proximity error* — Measured value of *feature inter-proximity error*, stating as mandatory information in addition to that of *measured feature width*:

- the number of measurement points used per pitch or surrounding mask area (recommendation is > 1. Then the mean value is used).

and as optional information:

- the measured area on the mask, and
- the spatial distribution of measurement locations.

SEMI G1-96
SPECIFICATION FOR CERDIP PACKAGE CONSTRUCTIONS

NOTE: This entire document was revised in 1996.

1 Purpose

This specification defines the materials and acceptance criteria for the components (bases, window frames, and caps) or sub-assemblies (leadframes mounted in a sandwich between bases and window frames) used for cerdip package constructions.

NOTE 1: Materials and acceptance criteria for leadframes, purchased separately for these constructions, are described in SEMI G2.

2 Scope

This specification applies to all cerdip (dual-in-line) packages which have either:

- A leadframe sandwiched between two ceramic pieces — the base and a window frame — and sealed by a solder glass layer, and a cap with a similar seal; or,
- A leadframe mounted into a solder glass layer on a ceramic base, and a cap with a similar glass seal layer.

NOTE 2: The base, leadframe, and, if required, the window frame may be purchased as separate components or as a sub-assembly.

3 Units

This specification uses U.S. Customary (inch pound) units as the prime unit.

4 Referenced Documents

4.1 *Order of Precedence*

To avoid conflicts, the order of precedence when ordering components or sub-assemblies for cerdip packages shall be as follows:

- Purchase order
- User's package drawings
- This specification
- Reference documents
- Related documents

4.2 *Referenced Documents*

4.3 *SEMI Specifications*

5 Terminology

5.1 *blister (bubble) metallization* — An enclosed, localized separation of the metallization from its base material (such as ceramic or other metallization layer component) that does not expose the underlying layer.

5.2 *burr* — An adherent fragment of parent material at a component edge. In leadframes, the metal burr, due to the stamping operation, may be in the horizontal or vertical direction to the surface. In ceramic packages, this type of characteristic is called a fin.

1 American National Standards Institute, 1430 Broadway, New York, NY 10018

2 Joint Electronic Development Engineering Council, 2001 Eye Street, N.W., Washington, D.C. 20006

3 Military Standards, Naval Publications and Form Center, 5801 Tabor Avenue, Philadelphia, PA 19120

5.3 *camber (ceramic)* — Arching of a nominally flat ceramic body.

5.4 *chip* — A region of material missing from a component (e.g., ceramic from a package, or solder from a preform). The region does not progress completely through the component and is formed after the component is manufactured. Chip size is defined by its length, width, and depth from a projection of the design planform. Also called chipout (see Figure 1).

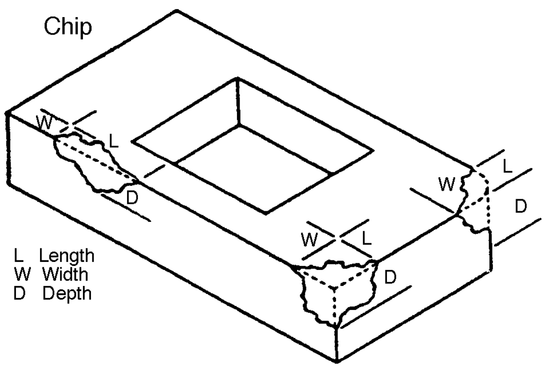

Figure 1

5.5 *crack* — A cleavage or fracture that extends to the surface of a semiconductor package or solder preform.The crack may or may not pass through the entire thickness of the package or preform.

5.6 *critical seal area* — On a semiconductor package, the area bounded by the shortest nominal design distance from the largest cavity, usually the wire bond cavity, to the edge of the package or ceramic layer forming the seal area (see Figure 2).

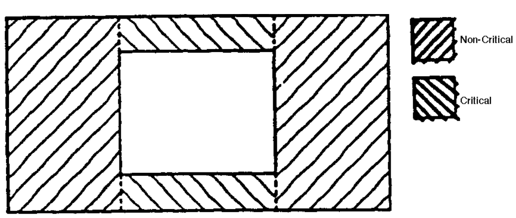

Figure 2
Critical and Non-Critical Seal Area

5.7 *fin* — On a ceramic package or cap, a fine feathery-edged projection of parent ceramic material on the corner of the ceramic body.

5.8 *foreign material* — An adherent particle that is not parent material of the component. Adherence means that the particle cannot be removed by an air or nitrogen blast at 20 psi.

5.9 *glass flow* — On a semiconductor package or cap, the heating process which just removes all the screen printing mesh marks in the sealing glass when viewed at 10× magnification.

5.10 *glass void* — The absence of a sealing glass layer from a designated area.

5.11 *metallization void* — The absence of a clad, evaporated, plated, or screen-printed metal layer or braze from a designated area.

5.12 *non-critical seal area* — On a semiconductor package that uses a lid, cap, or cover to effect the seal, the area of the sealing surface outside the critical sealing area (see Figure 2).

5.13 *overhang* — On a semiconductor package, the horizontal extension of the sealing glass past the vertical wall of a cavity cut into the ceramic layer on which the glass is printed (see Figure 3).

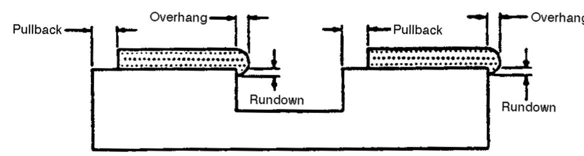

Figure 3
Glass Misalignment

5.14 *peeling (flaking)* — Any separation of a plated, vacuum-deposited, or clad metal layer from the base metal of a leadframe, pin heatsink, or seal ring, from an underplate or from a refractory metal on a ceramic package. Peeling exposes the underlying metal.

5.15 *projection* — On a semiconductor package (plastic or ceramic) leadframe or preform, an irregularly raised portion of a surface indigenous to the parent material.

5.16 *pullback* — On a semiconductor package, the linear distance between the edge of a cavity cut into a ceramic layer and the first measurable glass or metallization layer interface coated onto the top surface of that layer. The total pullback may be the result of the high-temperature processing required to manufacture the package or to coat the surface. It may also be the result of design considerations (see Figure 3).

5.17 *rundown* — On a semiconductor package, the linear distance from the upper surface of a ceramic cavity layer to the bottom point of the overhang into the cavity, of a sealing glass or metallization layer that has been screened onto that surface (see Figure 3).

5.18 *seal area* — On a semiconductor package, the area designated for sealing a cover or lid to a cofired ceramic package, to a cap to a cer-pack base.

5.19 *void* — An absence of metallization or glass from a designated metallized or glassed area on a ceramic surface.

6 Ordering Information

Purchase orders for cerdip components or sub-assemblies furnished to this specification shall include the following items:

6.1 Current drawing revision detailing:

6.1.1 All dimensions and tolerances per ANSI Y14.5M practices

6.1.2 Type and color of ceramic

6.1.3 Type and thickness of glass

6.1.4 Type and thickness of die pad metallization

NOTE 3: If sub-assemblies are purchased, the leadframe details shall be as described in SEMI G2. In some cases, unlike the frames described in SEMI G2, the leadframes may also have a die-attach pad. If required, the external lead plating requirements for these sub-assemblies shall also be specified. (See SEMI G20 for general details of lead finishes.) If sub-assemblies are purchased, leadframe inspection shall follow the requirements detailed in Section 9.

6.2 *Incoming Inspection and Functional Tests* — See Sections 9 and 10.

6.3 *Incoming Sampling Procedures* — See Section 11.

6.4 *Packaging and Marking Requirements* — See Section 12.

6.5 *Vendor Certification Requirements* — See Section 13.

6.6 Any additions to, or variations from, this specification.

7 Dimensions

The components or sub-assemblies described in this specification shall produce packaged devices that conform to the outline dimensions and lead numbering for cerdip package constructions detailed in:

— JEDEC Publication 95 and

— MIL-STD-1835.

Package manufacturing tolerances shall be agreed upon between user and supplier and detailed in the drawings.

Typical dimensions and tolerances for standard bases and caps are shown in the appendices at the end of this specification.

8 Materials

The definitions defect criteria and functional tests described in this specification relate to package components made with the following materials:

8.1 *Bases, Window Frames, and Caps*

8.1.1 *Material* — Ceramic with 90% alumina, minimum content.

8.1.2 *Color* — Black, dark brown, or dark violet.

8.2 *Sealing Material*

8.2.1 *Material* — Solder glass designed to seal metal (typically Iron-Nickel-Cobalt alloy per MIL-M-38150, Type A or Iron-Nickel alloy per MIL-M-38150 Type B) to ceramic.

8.3 *Die-Attach Pad*

8.3.1 *Material* — Thick film gold or other specified material.

8.4 *Leadframe*

8.4.1 Leadframes, whether purchased as component or in sub-assemblies, shall conform to the requirements of SEMI G2 as required.

9 Defect Limits

The following defects shall be cause for rejection if the limits shown are exceeded:

NOTE 4: The criteria apply to purchased components and pre-assemblies, as applicable, or, where applicable, to units assembled by the user to process conditions agreed upon between the user and supplier.

9.1 *Ceramic Components*

9.1.1 *Cracks* — Any crack.

9.1.2 *Chips* — See Figures 1 and 2.

9.1.2.1 *Corner Chips* — 0.030" (0.762 mm) × 0.030" (0.726mm) × 25% of the package element thickness.

9.1.2.2 *Edge Chips* — 0.100" (2.54 mm) × 0.030" (0.726mm) × 25% of the package element thickness.

9.1.2.3 *Critical Seal Area* — Chips shall not reduce the critical seal path, at any point, more than 30%. No more than four chips are allowed in this area, regardless of loss of seal length.

9.1.3 *Burrs, Projection (Fins), and Blisters*

9.1.3.1 *Bases, Caps, and Window Frames* — 0.005" (0.127 mm) maximum allowable dimension in the plane of the component, or greater than 0.003" (0.076 mm) in height.

9.1.3.2 *Die-Attach Surface (on Base Ceramic)* — 0.005" (0.127 mm) dimension in the plane of the component, or greater than 0.001" (0.254 mm) above the surface of the metallization excluding a zone, 0.010" (0.254 mm) wide, around the periphery of the cavity.

9.1.4 *Camber* — Shall be agreed upon between user and supplier and specified on the component or sub-assembly drawing. Standard limits shall be 0.003"/inch (0.003 mm/mm), maximum, with a minimum allowable camber of 0.002" (0.051 mm).

9.1.5 *Foreign Material* — 0.020" (0.508 mm) maximum allowable surface dimension or 0.005" (0.127 mm) in height. No more than three sites allowed and a minimum separation of 0.030" (0.762 mm) between sites.

9.2 *Glass Sealant*

9.2.1 *Chips and Voids* — 0.010" (0.025 mm) maximum allowable dimension. In the critical seal, there shall be no more than four acceptable chips or voids. In critical and non-critical seal areas, there shall be no voids after a glass flow cycle.

9.2.2 *Glass Misalignment* — (After glass flow on components, see Figure 3, or on sub-assemblies.)

9.2.2.1 *Glass Overhang* — 0.015" (0.381 mm) maximum extension from the ceramic edge.

9.2.2.2 *Glass Rundown* — 50% of the package element thickness.

9.2.2.3 *Glass Rundown into the Die-Attach Cavity* — 0.010" (0.254 mm) maximum extension from the ceramic surface into the cavity.

9.2.2.4 *Glass Pullback (After Glass Flow)* — See Table 1 and Figure 3.

Table 1 Maximum Allowable Pullback

Area of Package	*Package Row Spacing*	*Package Row Spacing*
	0.300" (7.500 mm) and 0.400"(10.16 mm)	0.600" (15.24 mm) and larger
Side external (critical seal area)	0.010" (0.254 mm)	0.015" (0.381 mm)
Side external (non-critical seal area)	0.015" (0.381 mm)	0.015" (0.381 mm)
End external	0.020" (0.508 mm)	0.020" (0.508 mm)
Side cavity	0.010" (0.254 mm)	0.015" (0.381 mm)
End cavity	0.010" (0.254 mm)	0.015" (0.381 mm)
Maximum allowable critical seal length reduction on any one side, as measured between the cavity and the external side	0.015" (0.381 mm)	0.020" (0.508 mm)

NOTE 5: Regardless of the maximum criteria noted in Table 1, the critical seal length at any point shall not be reduced any more than 30%.

9.2.2.5 *Foreign Material* — 0.020" (0.508 mm) maximum allowable surface dimension in the plane of the glass, but 0.010" (0.254 mm) in the critical seal area, with no more than three sites allowed and a minimum separation of 0.030" (0.762 mm) between sites.

9.3 *Die-Attach Cavity Metallization (0n Ceramic Base)* — Excluding a 0.010" (0.254 mm) wide zone around the periphery of the cavity, the following criteria shall apply:

9.3.1 *Foreign Material, Including Glass Splatters* — 0.005" (0.130 mm) maximum in the plane of the metallization or greater than 0.001" (0.025 mm) in height with no more than three sites allowed and a minimum separation of 0.030" (0.763 mm) between sites.

9.3.2 *Metallization Nodules* — No more than three allowed. If the metallization is gold and gold-silicon eutectic die attach is to be used, the bumps may not exceed 0.010" (0.254 mm) in the surface dimension or 0.005" (0.130 mm) in height. If silver glass or resin bonding is to be used, the nodules shall be treated as foreign material per Section 9.3

9.4 *Leadframe*

NOTE 6: The criteria described in this section generally apply to leadframe inspection for purchased sub-assemblies. Where appropriate, the criteria may be used for sub-assemblies manufactured in-house with purchased components. For information on the criteria for leadframes purchased separately, see SEMI G2.

9.4.1 *Lead Bond Areas* — The minimum lead bond area on the lead tip is defined in Figure 4.

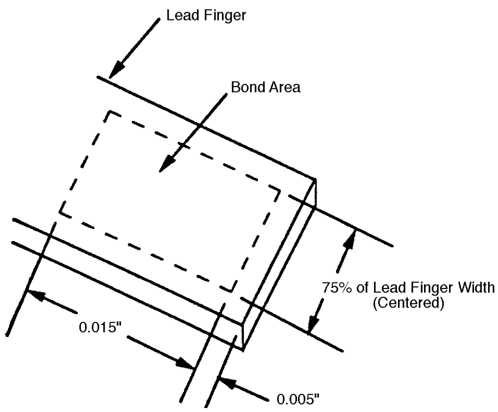

Figure 4

9.4.1.1 *Voids or Pits* — Exposure of base metal with any dimension greater than 0.001" (0.025 mm).

9.4.1.2 *Discoloration, Blistering, or Peeling of the Metallization*

9.4.1.3 *Scratches or Scrapes* — Any build-up of metallization or exposure of base metal.

9.4.1.4 *Foreign Material, Including Glass Splatter or Projections* — No more than three sites, each with a maximum dimension in any plane of 0.001" (0.025 mm).

9.4.1.5 *Glass Wetting or Cracking* — For purchased sub-assemblies, any lead finger which is not firmly embedded in the glass.

9.4.1.6 *Glass Pullback from the Lead Tip* — 0.010" (0.254 mm) maximum.

9.4.1.7 *Glass Bulge between Lead Fingers (Purchased or In-House Sub-Assemblies)* — 0.005" (0.127 mm) height above the fingers except as agreed upon between user and supplier for narrow pitch leads where this limit may cause wire bond interference problems.

9.4.1.8 *Lead Tip Coplanarity* — 0.006" (0.15 mm) maximum allowable difference in the position of the top surface of the lead from highest lead to lowest lead.

9.4.1.9 *Lead Tip Pitch* — ± 0.002" (0.508 mm) maximum allowable variation from true position.

9.4.2 *Internal Lead Areas, Excluding Lead Bond Areas*

9.4.2.1 *Burrs, Projections, and Pits* — 0.002" (0.508 mm) maximum allowable depth or height.

9.4.2.2 *Foreign Material, Including Plating Discoloration* — 0.015" (0.381 mm) maximum surface dimension or exceeding 0.002" (0.508 mm) in height.

9.4.2.3 *Voids* — Any exposure of base metal with a major dimension greater than 0.002" (0.508 mm).

9.4.2.4 *Blistering or Peeling of Metallization*

9.4.2.5 *Scratches and Scrapes* — Any build-up of metallization or exposure of base metal.

9.4.3 *External Lead Areas — Unplated*

NOTE 7: Non-functional areas of the leadframe, such as tie bars, shall not be subjected to inspection unless they interfere with handling equipment.

9.4.3.1 *Scratches* — Any scratch causing a loss of more than 25% of the leadframe thickness.

9.4.3.2 *Voids* — Any void which violates the criteria of Section 9.4.3.1 or causes a loss of more than 10% of the design width of a leadframe detail.

9.4.3.3 *Burrs* — In excess of 0.002" (0.051 mm) in height and 0.005" (0.127 mm) in the major dimension.

9.4.4 *External Leads — Plated*

NOTE 8: Non-functional areas of the leadframe, such as tie bars, shall not be subjected to inspection unless they interfere with handling equipment.

9.4.4.1 *Scratches* — Any scratch causing a loss of more than 25% of the leadframe thickness.

9.4.4.2 *Voids* — Any void which violates the criteria of Section 9.4.3.1 or causes a loss of more than 10% of the design width of leadframe detail.

9.4.4.3 *Burrs* — In excess of 0.002" (0.051 mm) in height and 0.005" (0.127 mm) in the major dimension.

9.4.4.4 *Scratches and Scrapes* — Any exposure of the base metal or loss of plating integrity over more than 5% of a lead finger.

9.4.4.5 *Voids* — Any exposure of base metal.

9.4.4.6 *Blistering or Peeling*

9.4.5 *Leadframe/Base/Window Assembly*

9.4.5.1 *Lead Tip Overhang* — 0.010" (0.254 mm) maximum from the cavity wall (see Figure 5).

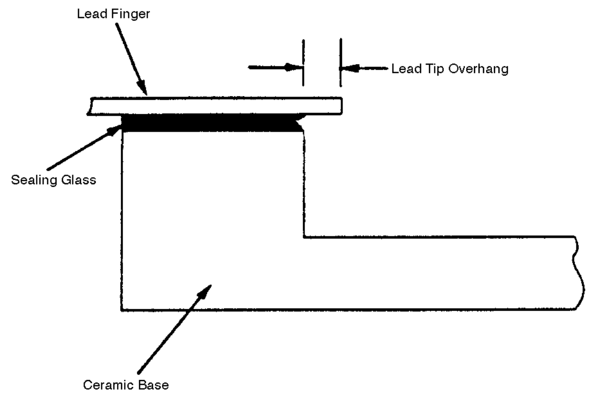

Figure 5

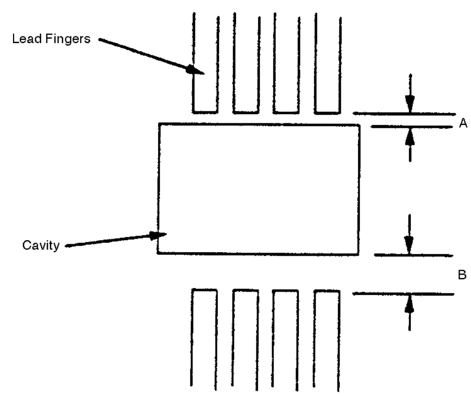
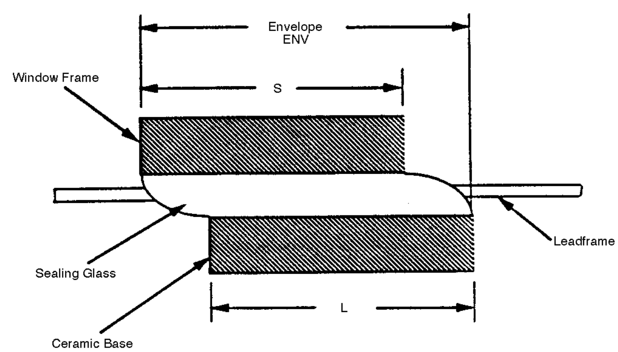
9.4.5.2 *Lead Misalignment to Ceramic Base* — 0.010" (0.254 mm) maximum (see Figure 6).



$\frac{A - B}{2} \leq 0.010"$

Figure 6

9.4.5.3 *Window Assembly Misalignment* — 0.015" (0.358 mm) maximum (see Figure 7).



$ENV - L + \frac{L - S}{2} \leq 0.015"$

Figure 7

9.4.6 *Die-Attach Pad (Leadframe)*

9.4.6.1 Flatness across the pad and parallelism to the base and window shall be agreed upon between user and supplier.

9.4.6.2 *Voids or Pits* — Exposure of base metal with any dimension greater than 0.001" (0.025 mm).

9.4.6.3 *Discoloration, Blistering, or Peeling of the Metallization*

9.4.6.4 *Scratches or Scrapes* — Any build-up of metallization or exposure of base metal.

9.4.6.5 *Foreign Material, Including Glass Splatter or Projections* — No more than three sites, each with a maximum dimension in any plane of 0.001" (0.025 mm).

9.4.7 *Mechanical Damage — Leads*

9.4.7.1 *Broken, Kinked, or Missing Leads*

9.4.7.2 *Twist* — Any lead twisted by more than 10° from the untwisted condition.

9.4.7.3 *Bottom-Formed Width* — Any sub-assembly with the bottom-formed width of the leadframe exceeding ± 0.010" (0.254 mm).

9.4.7.4 *Top-Formed Width* — Any sub-assembly with the top-formed width of the leadframe exceeding ± 0.010" (0.254 mm).

10 Incoming Inspection and Functional Tests

10.1 *Incoming Inspection*

10.1.1 Dimensional Inspection per Section 7.

10.1.2 Visual inspection per Section 9 at 10× magnification with vertical lighting.

10.1.3 *Metallization*

10.1.3.1 *Die-Attach Metallization* — Thickness shall be measured by standard cross-sectioning without smearing or by X-ray fluorescence.

10.1.3.2 *Lead Bond Metallization* — Thickness shall be measured by X-ray fluorescence.

10.1.3.3 *External Lead Plating (If Applicable)* — Thickness shall be measured by X-ray fluorescence.

10.1.4 *Lead Solderability (If Applicable)* — Tested in accordance with MIL-STD-883, Method 2003.

10.2 *Functional Testing*

NOTE 9: All procedures to functionally test the components or sub-assemblies shall be agreed upon between user and supplier.

The sequence of functional testing (and subsequent environmental testing) shall be as shown in Figure 8.

10.2.1 *Die Attach*

10.2.1.1 *Visual Inspection*

- Eutectic Bonding — Visually inspect the alloy wet-out after die attach. The minimum wet out requirement shall be 100% of the die perimeter.
- Silver Glass or Resin Bonding — 100% die perimeter coverage shall be required.

NOTE 10: 100% coverage for silver glass or resin bonding is not a function of base acceptability but is required to standardize die shear testing. The inability of the resins to wet the surface of the die attach area due to contamination is cause for rejection.

10.2.1.2 *Die Shear Test* — Perform destructive testing in accordance with MIL-STD-883, Method 2019.

NOTE 11: Test may also be performed after environmental testing. In the case of very large die, this test may not be appropriate to fully evaluate the package. In these cases, die sizes agreed upon between user and supplier shall be used. Alternatively, die pull testing may be used by agreement between user and supplier. Inspection for die attach voids may be performed radiographically in accordance with Section 10.2.1.3 in order to ensure that the die attach process does not contribute to an incorrect evaluation of the shear or pull test results. In the case of eutectic die attach, the results from these methods may also be indicative of poor functionality of the gold die-attach metallization.

10.2.1.3 *Void Inspection* — Inspection for die-attach voids may be performed radiographically in accordance with MIL-STD-883. Method 2012 or ultrasonically in accordance with MIL-STD 883, Method 2030.

10.2.2 *Wire Bond* — On wire bonds which meet the requirements of MIL-STD-883, Method 2010, perform destructive pull testing in accordance with MIL-STD-883, Method 2011, Test Condition D.

NOTE 12: Bonds which cause lifted metallization from the lead fingers shall also be cause for rejection.

NOTE 13: This test may be performed at pre seal and post-seal.

10.2.3 *Seal*

10.2.3.1 *Visual Inspection* — The glass sealant appearance and flow shall be visually inspected for conformance to criteria agreed upon between user and supplier.

10.2.3.2 *Hermeticity* — Performed in accordance with MIL-STD-883, Method 1014, Test Condition A or B and C, the package must maintain hermetic integrity after each environmental test or sequence of tests.

NOTE 14: Internal water-vapor content may also be measured in accordance with MIL-STD-883, Method 1018.

10.2.3.3 *Cap Torque Test* — The failure criteria shall be agreed upon between user and supplier.

10.2.4 *Lead Finish* — Plate according to a process agreed upon between user and supplier.

10.2.5 *Lead Trim*

10.3 *Environmental Testing* — Environmental evaluation shall include, but not be limited to, the following tests:

NOTE 15: The sequence of testing and the sample sizes for each sub-group shall be agreed upon between user and supplier.

10.3.1 *Temperature Cycle* — In accordance with MIL-STD-883, Method 1010, Condition C.

10.3.2 *Thermal Shock* — Per MIL-STD-883, Method 1011, Condition B.

10.3.3 *Vibration Fatigue* — In accordance with MIL-STD-883, Method 2005, Test Condition B.

10.3.4 *Mechanical Shock* — In accordance with MIL-STD-883, Method 2002, Test Condition B.

10.3.5 *Constant Acceleration* — In accordance with MIL-STD-883, Method 2001, Test Condition A.

10.3.6 *Moisture Resistance* — In accordance with MIL-STD-883, Method 1004.

10.3.7 *Additional Testing* — Additional tests performed during package qualification may include evaluation of electrical and thermal characteristics, corrosion resistance and alpha particle emissions. These tests may be performed on a periodic basis to maintain package qualification. These tests may include, but are not limited to, the following:

10.3.7.1 *Insulation Resistance* — In accordance with MIL-STD-883, Method 1003, to test conditions agreed upon between user and supplier.

10.3.7.2 *Lead Inductance* — In accordance with SEMI G23 or using an impedance analyzer by a method agreed upon between user and supplier.

10.3.7.3 *Lead-to-Lead Capacitance* — Per SEMI G24.

10.3.7.4 *Lead Resistance* — Per SEMI G25.

10.3.7.5 *Junction-to-Case Thermal Resistance* — In accordance with SEMI G30 or a wind tunnel method agreed upon between user and supplier.

10.3.7.6 Alpha particle emission shall be tested by a method and to limits agreed upon between user and supplier.

10.3.7.7 *Salt Atmosphere (Corrosion) Testing* — In accordance with MIL-STD-883, Method 1009, 10.3.7.8 Condition A shall be performed to conditions agreed upon between user and supplier.

11 Sampling

The sampling plan used at incoming inspection shall be based on MIL-STD-105 and agreed upon between user and supplier (see Figure 8).

12 Packaging, Marking, and Packing List

12.1 *Packaging* — The shipping containers and materials shall be suitably designed to provide the components or sub-assemblies with protection against normal transportation damage risks which include crushing, spillage, and exposure to moisture and other corrosive gases.

The inner packaging materials must not cause particulate contamination of the components or sub-assemblies and shall be cleanroom compatible as defined by the user. The components or sub-assemblies, in packing trays, shall be vacuum-sealed in a bag with a desiccant.

12.2 *Marking*

12.2.1 *Internal Packages* — Each internal package shall be clearly marked with the following information, as appropriate:

- User's part number,
- User's purchase order number,
- Drawing number (user's and/or supplier's, as requested by user),
- Quantity, and
- Date of manufacture.

The package shall also contain any agreed upon certification data.

12.2.2 *External Packages* — The packing list on the outside of the external package shall contain the following information:

- User's part number,
- User's purchase order number,
- Quantity,
- Shipping date, and
- Any specific instructions for receiving dock personnel.

13 Certification

13.1 Upon request of the user in the contract or purchase order, a supplier's certification that the product was manufactured and tested in accordance with this specification, together with a report of the test results, shall be furnished at the time of shipment. However, if the user does perform inspection and test on a certified shipment, and the product fails to meet the requirements, the product shall be subject to rejection.

13.2 If the user and supplier agree, the product may be certified as capable of meeting this specification. In this context, capable of meeting signifies that the supplier is not required to perform all the inspections and tests. However, if the user does perform inspection and test on a certified shipment, and the product fails to meet the requirements, the product shall be subject to rejection.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI G2-94
SPECIFICATION FOR METALLIC LEADFRAMES FOR CER-DIP PACKAGES

1 Preface

1.1 *Purpose* — This specification defines the materials and dimensions for the metallic leadframe (stamped or etched) used in the construction of Cer-DIP Package.

1.2 *Scope* — The criteria detailed in this document applies to the iron-nickel leadframe (MIL-M-38510 Type A or Type B) used in Cer-DIP packages.

1.3 *Units* — U.S. Customary (inch-pound) or metric (SI) units may be used at the customer's discretion. This specification uses the U.S. Customary units as the prime unit.

2 Referenced Documents[1]

2.1 This document specifically refers to:

MIL-I-23011 — Iron/Nickel Alloys for Sealing to Glasses and Ceramics

MIL-M-38510 — General Specifications for Microcircuits

MIL-STD-883 — Test Methods and Procedures for Microelectronics

2.2 Related information may also be found in:

MIL-STD-105 — Sampling Procedures and Tables for Inspection by Attributes

3 Terminology

bonding area — Coined area on bond fingers within a distance of 0.762 mm (0.030") from lead tips.

bottom formed width — See Figure 3.

bow — Curvature of the leadframe strip in the vertical plane; see Figure 1.

burr — Fragment of excess parent material attached to the leadframe edges.

camber — Curvature of the leadframe strip edge in the horizontal plane; see Figure 2.

coined area — The area of the bond fingers planished to produce a flattened area for functional use; see Figure 3.

coplanarity — The total indicator reading difference of the lead tips in the Z direction.

datum plane — M is datum plane; see Figure 3.

discoloration — A darkening or staining of the aluminum (metallization).

foreign material — Any adhering residue which is not part of the leadframe composition.

pit — A shallow surface depression or crater with a visible edge.

planarity — Total indicator reading of the lead tips in the Z direction relative to datum M.

projection — A raised portion of the surface indigenous with the parent material, other than a burr.

slug marks — Random dents in the leadframe.

stamped leadframe terminology — See Figure 3.

tilt — The deviation of the plane of the coined area from a condition parallel to the plane on datum M.

top formed width — See Figure 3.

twist — The angular rotation of one end of the leadframe or strip with reference to the other end; see Figure 4.

void — An absence of aluminization from a designated area of the leadframe.

4 Ordering Information

Purchase order for Cer-DIP metallic leadframes furnished to this specification shall include the following items:

4.1 Current drawing of the leadframe showing all dimensions and tolerances, including the location of the metallization layer.

4.2 Material,

4.3 Number of leads,

4.4 Material tensile strength,

4.5 Metallization thickness and type,

4.6 Form of leadframes (i.e., singles, scored strips, or unscored strips),

4.7 Number of frames per strip; as applicable,

4.8 Material certification,

4.9 Packaging and marking.

1 Military Standards, Naval Publications and Form Center, 5801 Tabor Ave., Philadelphia, PA 19120

5 Dimensions

All Dimensioning and tolerancing shall conform to Y14.5. Table 1 presents standard leadframe dimensions.

6 Materials

6.1 *Leadframe Base Material* — Tensile strength shall be specified per MIL-I-23011.

6.1.1 *Chemical Composition* — Shall conform to the requirements of MIL-M-385l0, Type A or B.

6.1.2 *Material Tensile Strength* — Shall be supplied per MIL-I-23011.

6.2 *Metallization* — Aluminum

6.2.1 *Thickness* — 100 microinches minimum, 600 microinches maximum (micromin, micromaximum).

6.2.2 *Coverage* — 0.030" (0.762 mm) minimum; measured from lead tip. Maximum to be determined by ceramic size.

6.2.3 *Composition*

6.2.3.1 *Clad Material* — 99.4% minimum aluminum.

6.2.3.2 *Vapor Deposition* — 99.9% minimum aluminum.

NOTE: The two types of aluminum may exhibit different visual appearances and non-functional characteristics after processing.

7 Defect Limits

7.1 *Burrs*

7.1.1 *Horizontal*

7.1.1.1 *Bonding Area* — 0.001" (0.025 mm) max.

7.1.1.2 *Other Areas* — 0.002" (0.051 mm) max.

7.1.2 *Vertical*

7.1.2.1 *Bonding Area* — 0.001" (0.025 mm) max.

7.1.2.2 *Other Areas* — 0.002" (0.051 mm) max.

7.2 *Planarity/Coplanarity* — Shall not exceed the limits shown in Table 2.

7.3 *Foreign Materials* — Leadframes shall be clean and free from foreign material such as photoresist, lubricants, solvent residue, water marks, and rust spots. Protective coatings acceptable to both vendor and user are not considered foreign material.

7.4 *Pits and Slug Marks*

7.4.1.1 *Bonding Area* — 0.001" (0.025 mm) max. surface dimension × 0.0005" (0.013 mm) maximum depth.

7.4.1.2 *Other Areas* — 0.010" (0.254 mm) max. surface dimension × 0.0005" (0.013 mm) maximum depth.

7.5 *Projections*

7.5.1 *Bonding Area* — None allowed.

7.5.2 *Other Areas* — .010" (.254 mm) max. surface dimension × 0.002" (0.015 mm) maximum height.

7.6 *Scratches* — There shall be no scratches in the aluminum metallization that penetrate to the underlying base material.

7.7 *Voids* — All metallized areas of the leadframe within the bonding area shall have no voids larger than 0.001" (0.025 mm) in any dimension.

7.8 *Twist* (formed leadframe strip) — 0.004 inch per inch (0.102 mm).

7.9 *Coining*

7.9.1 *Coined Depth* — Minimum 0.0005" (0.013 mm); maximum 0.002" (0.051 mm). Minimum coined depth may be controlled by minimum flat area.

7.9.2 *Coined Flat Area* — Minimum of 80% of normal lead width; measured 0.005" (0.127 mm) back from lead tip.

7.9.3 *Coined Length* — Minimum 0.025" (0.635 mm) from lead tip.

7.10 *Lead Position*

7.10.1 *Lead Position* — A 0.007" (0.178 mm) diameter circle must be 100% within nominal lead position when centered at lead nominal centerline and 0.007" (0.178 mm) back from lead tip.

7.10.2 *Minimum Spacing* — 0.006" (0.152 mm) minimum.

7.11 *Bowing*

7.11.1 *Convex* — 0.0025 inch per inch (0.0025 mm per mm) maximum.

7.11.2 *Concave* — 0.0025 inch per inch (0.0025 mm per mm) maximum.

7.12 *Camber* — 0.005 inch per inch (0.005 mm per mm) maximum.

NOTE: Items 7.11 and 7.12 refer to scored strips only.

8 Sampling

Sampling will be determined between vendor and customer.

9 Test Methods

9.1 *Sequence of Events and Tests*

The sequence of testing should be:

9.1.1 Degrease

9.1.2 Metallurgical Bond Adhesion (Section 9.3.1)

9.1.3 Frame Attach

9.1.4 Die Attach

9.1.5 Bond

9.1.6 Pre-Seal Bond Pull (Section 9.3.2)

9.1.7 Seal

9.1.8 Mechanical Testing (Section 9.2)

9.1.9 Lead Trim

9.1.10 Post-Seal Bond Pull (Section 9.3.2)

NOTE: It is acknowledged that the leadframe manufacturer may not perform all these tests due to equipment and component limitations. Regardless, leadframes must fulfill these requirements, subject to the influence of the testing facility and associated components.

9.2 *Mechanical and Thermal*

9.2.1 *Temperature Cycling* — Per MIL-STD-883, Method 1010.4, Condition C.

9.2.2 *Thermal Shock* — Per MIL-STD-883, Method 1011.2, Condition C.

9.2.3 *Centrifuge* — Per MIL-STD-883, Method 2001.2, Condition E.

9.2.4 *Lead Integrity*

9.2.4.1 A 500°C ± 20° - 55% R.H. heat soak for 15 minutes ± 1 minute. Cooled at no more than 50°C per minute. Afterwards the frame is clamped between plates of a suitable size for the lead spacing (see Section 9.2.4.2). Then (3) 90° cycles are performed. Frames are examined at 20× magnification and if cracks are observed at the Apex A (Figure 3), then the frame is rejected.

9.2.4.2 Plate shall be of equivalent plan-form to the ceramic being employed for the particular frame. An edge radius equivalent to 2T, where T is the leadframe thickness, shall be on the contacting surface of the plate.

9.3 *Functional Test Methods*

9.3.1 *Metallurgical Bond Adhesion Aluminization* — The metallurgical bond between the aluminization and the base metal shall permit the leadframe to be heated in air to 525°C ± 10°C for five (5) minutes minimum without evidence of aluminum peeling, blistering, or discoloring when viewed at 20× magnification. (Discoloration must not jeopardize the user's standard part reliability.) Subsequently, the aluminized layer must pass the following two adhesion tests:

9.3.1.1 A cellophane type adhesive tape is firmly applied to the aluminization and removed toward the center of the cavity in a continuous rapid motion. This test is to be performed over the same area three times. No evidence of aluminum separation from the base metal shall be visible at 20× magnification

9.3.1.2 The aluminization shall be capable of passing a functional wirebond test without separating.

9.3.2 *Lead Bond Quality* — Minimum pre-seal and post-seal bond strength test per MIL-STD-883, Method 2011.2, Test Condition D. Applicable failure categories: A-4 and A-6.

10 Packaging and Marking

10.1 *Packaging* — The shipping containers and materials shall be suitably designed to provide the singulated components with protection against normal transportation damage risks which include crushing, abrasion and spillage, and exposure to moisture and other corrosive gases. The inner packing materials must not cause particulate contamination on the components and shall be clean-room compatible as defined by the customer. The components, in packing trays, shall be sealed in a vacuum bag with a dessicant.

10.2 *Packing List*

10.2.1 *Internal Packages* — Each internal package shall be marked as follows:

User Part Number

User Purchase Order Number

Drawing Number (User's and Supplier's, if appropriate)

Supplier Shipping Lot Number

Quantity

Date of Manufacture

10.2.2 *External Packages* — The Packing List, located on the outside of the container, shall provide the following information:

User's Part Number

User's Purchase Order Number

Quantity

Shipping Date

Any specific instructions for receiving dock personnel.

Stamped Leadframe Terminology

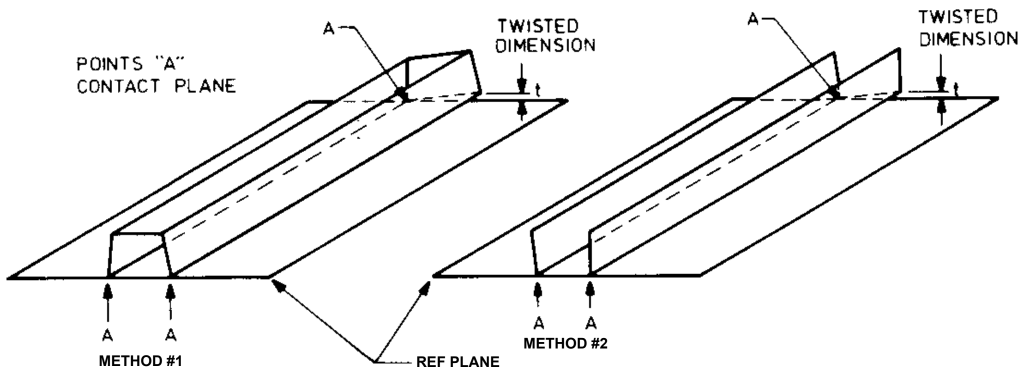

Figure 4
Twist Strip

Using surface plate, establish a reference plane the whole length of the frame strip. Place frame strip, either method 1 or 2, whichever method gives a 3 point contact with reference plane A, using thickness gauges to determine height between reference plane and 4th point noted as t. This measurement will determine frame twist over entire length.

SEMI G3-90
SPECIFICATION FOR SIDEBRAZED LAMINATES

1 Preface

This specification covers laminated ceramic sidebrazed packages of 7.62 mm (0.003"), 10.16 mm (0.400"), 15.24 mm (0.600") and 22.86 mm (0.900") nominal widths. The leadframe which is brazed to this type of package is included in this specification.

2 Applicable Documents[1]

2.1 This following applicable documents, of the revision currently in effect, are part of this specification to the extent referenced herein.

MIL-STD-105 — Sampling Procedures and Tables for Inspection by Attributes

MIL-STD-883 — Test Methods and Procedures for Microelectronics

MIL-G-45204 — Gold Plating, Electro-Deposited

MIL-M-38510 — General Specification for Microcircuits

3 Selected Definitions

burr — An adherent fragment of excess parent material at the component edge.

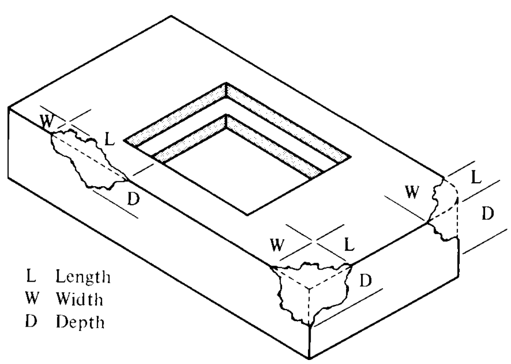

Figure 1
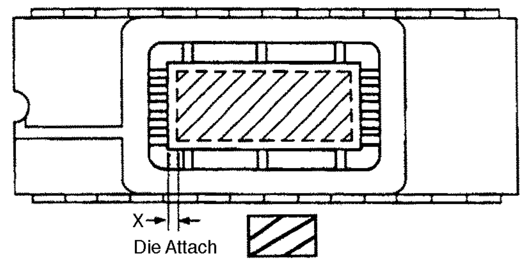
Chip Illustration

chip — A region of ceramic missing from the surface or edge of a package which does not go completely through the package. Chip size is given by its length, width and depth from a projection of the design plan-form. (See Figure 1.)

crack — A cleavage or fracture that extends to the surface of a package. It may or may not pass through the entire thickness of the package.

die attach surface — See Figure 2.



Package Row Spacing			
7.62 mm (.300")	10.16 mm (.400")	15.24 mm (.600")	22.86 mm (.900")
X = .203 mm (.008")	X = .254 mm (.010")	X = .381 mm (.015")	X = .508 mm (.020")

Figure 2
Die Attach Surface

discoloration — Any change in the color of the package plating as detected by the unaided eye after the application of heat per Section 9.1.1.

foreign material — An adherent particle other than parent material of that component.

LSI — Large scale integration.

layer — A ceramic or metallized layer that performs a discrete function as a part of the package. Should a layer be comprised of more than one ceramic laminate, all of those laminates shall be considered as comprising one layer if all are common in both plan-form and function. Leadframes shall not be considered as layers.

MSI — Medium scale integration.

projection — An adherent fragment of excess material on the component surface.

pullback — The linear distance between the edge of the ceramic and the first measurable metallization interface. (See Figure 3.)

rundown — See Figure 3.

1 Military Standards, Naval Publications and Form Center, 5801 Tabor Ave., Philadelphia, PA 19120

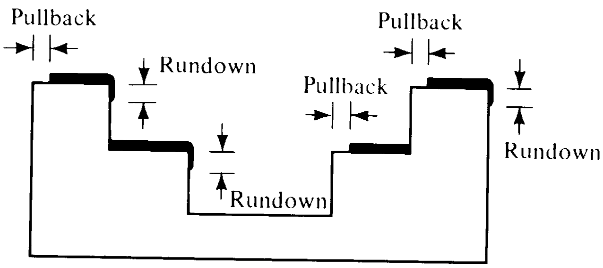


Figure 3
Metallization Misalignment

SSI — Small scale integration.

seal area — A dimensional outline area designated for either metallization or bare ceramic to provide a surface area for sealing. (See Figure 4.)

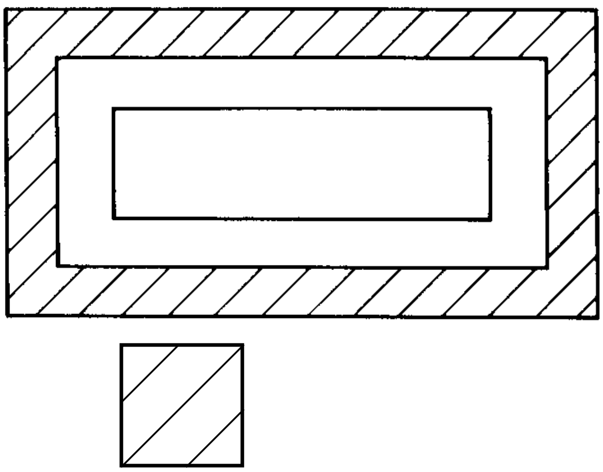

Figure 4
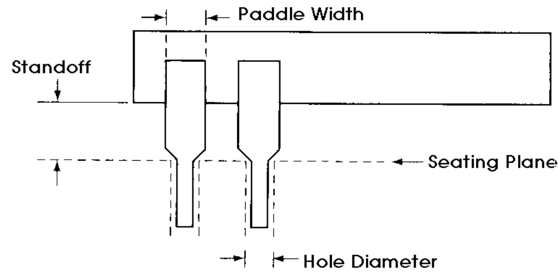
Seal Area

seating plane — See Figure 5.

standoff — Residual air gap after inserting the leads into a ground steel plate with a specific size hole and applying a specified downward pressure. (See Figure 5.)



NOTE: When determining the seating plane a downward of 10 grams is to be applied to the package.

Figure 5
Leadframe Paddle Width and Standoff

TIR — Total indicator reading.

VLSI — Very large scale integration.

void — An absence of metallization or plating from a designated area.

4 Ordering Information

Purchase orders for sidebrazed laminated packages furnished to this specification shall include the following items:

1. Drawing number and revision level
2. Number of leads and lead series spacing
3. Type and color of ceramic
4. Type and thickness of plating
5. Description (See Table 1.)
6. Thickness of individual layers of ceramic
7. Internal finger bonding pattern layout
8. Minimum exposed metallized bond finger length and width
9. Leads common to die attach area and/or seal ring
10. Sealing dimensions and flatness
11. Certification
12. Method of test and measurements (See Section 9.)
13. Lot acceptance procedures (See Section 8.)
14. Packaging and Marking (See Section 10.)

5 Dimensions and Permissible Variations

The dimensions of the sidebraze laminate packages shall conform as specified in Table 1.

6 Materials

6.1 *Ceramic*

6.1.1 Alumina content 90% minimum.

6.1.2 *Color* — Opaque or white.

6.2 *Metallization*

6.2.1 Refractory metallization (provide adequate bond strength to ceramic).

6.2.2 Nickel plating (if designated).

6.2.3 Precious or noble metal plating.

6.2.4 Nickel/gold per MIL-M-38510 except gold plating shall conform to MIL-G-45204, Type III and have a thickness of 60 microinches minimum.

6.3 *Braze Material* — An alloy with a melting point equal to or greater than 750°C which will provide specified bond strength of the lead to the ceramic.

6.4 *Lead Material*

6.4.1 Iron nickel cobalt alloy per MIL-M-38510, Type A.

6.4.2 Iron nickel alloy per MIL-M-38510, Type B.

7 Defect Limits

7.1 *Ceramic*

7.1.1 *Cracks* — None allowed.

7.1.2 *Chips*

7.1.2.1 *Corner* — 0.762 mm (0.030") × 0.762 mm (0.030") × 0.762 mm (0.030") max.

7.1.2.2 *Edge* — 2.54 mm (0.100") × 0.762 mm (0.030") × 0.762 mm (0.030") max. (Chips can not be encroached or exposed any metallized area.)

7.1.2.3 *Seal Area*

7.1.2.3.1 7.62 mm (0.300") and 10.16 mm (0.400") Row Spacing Parts — .762 mm (0.030") × 2.54 mm (0.100")

7.1.2.3.2 *15.24 mm (0.600") Row Spacing Parts* — 1.27 mm (0.050") × 0.381 mm (0.015") × 0.381 mm (0.015") max.

7.1.2.3.3 *22.86 mm (0.900") Rowing Spacing Parts* — 1.52 mm (0.060") × 0.508 mm (0.020") × 0.508 mm (0.020") max.

7.1.2.3.4 Chips cannot reduce the seal width by more than 1/3 of the design width.

7.1.3 *Burrs and Projections*

7.1.3.1 *Top Plane Excluding Seal Area* — 0.102 mm (0.004") max.

7.1.3.2 *Seal Area* — 0.025 mm (0.001") max. above metallization.

7.1.3.3 *Wire Bond Finger Areas* — 0.025 mm (0.001") max. above metallization.

7.1.3.4 *Die Attach Surface* — 0.025 mm (0.001") max. above metallization excluding a 0.203 mm (0.008") perimeter on 7.62 mm (0.300") centerline packages, 0.254 mm (0.010") perimeter on 10.16 mm (0.400") centerline packages and 0.381 mm (0.015") perimeter on 15.24 mm (0.600") centerline packages, 0.508 mm (0.020") perimeter on 22.86 mm (0.900") row center package.

7.1.4 *Camber* — Ceramic-maximum of 0.004 inch/inch (mm/mm).

7.1.5 *Flatness*

7.1.5.1 *Seal Area* — 0.050 mm (0.002") TIR on 7.62 mm (0.300") row center packages, 0.0635 mm (0.0025") TIR on 10.16 mm (0.400") and 15.24 mm (0.600") row center packages.

7.1.5.2 *Die Attach* — Die attach pad to be flat to within 0.051 mm (0.002") TIR to exclude a 0.203 mm (0.008") perimeter on 7.62 mm (0.300") centerline packages, 0.254 mm (0.010") perimeter on 10.16 mm (0.400") centerline packages and 0.381 mm (0.015") perimeter on 15.24 mm (0.600") centerline packages.

7.2 *Metallization*

7.2.1 *Voids*

7.2.1.1 *Seal Area* — On the outer half of the seal area width, maximum of 3 voids no larger than 0.127 mm (0.005") in diameter are permissible. On the inner half, maximum of 3 voids no larger than 0.381 mm (0.015") in diameter or larger than 1/3 of the seal area width, whichever is the smaller. The distance between any 2 voids shall be at least 0.762 mm (0.030").

7.2.1.2 *Wire Bond Fingers* — A 0.254 mm (0.010") × 0.010" (0.254 mm) void free area within the specified wire bond finger area as defined be the procurement drawing.

7.2.1.3 *Die Attach Surface* — Maximum 0.010" (0.254 mm) diameter by a distance greater than 0.030" (0.762 mm) with no more than 3 voids.

7.2.2 *Metallization Misalignment* — See Figure 3.

7.2.2.1 *Seal Plane Rundown* — Internal cavity — not to exceed 25% of the cavity layer thickness. External cavity — not to be less than 0.010" (0.254 mm) outside the cavity.

7.2.2.2 *Wire Bond Finger Pullback* — A 0.010" (0.254 mm) maximum from the cavity edge and the minimum exposed wire bond lead length must meet the dimension on the procurement drawing or specification.

7.2.2.3 *Wire Bond Finger Rundown* — Not to exceed 25% of the ceramic layer thickness or 0.005" (0.127 mm), whichever is the smaller.

7.3 *Lead Attachment*

7.3.1 *Voids in Braze*

7.3.1.1 *Gold Plated Leadframes* — 75% of the braze fillet will be void free.

7.3.1.2 *Nickel or Bare Leadframes* — 75% of the braze fillet will be void free.

7.3.2 *Lead Alignment*

7.3.2.1 *Misalignment Leads to Braze Pads* — The leads shall not overhang the braze pads by more than 25% of the measured paddle width nor reduce the clearance between adjacent pad or lead to less than 50% of the clearance between adjacent metallizations.

7.3.2.2 *Lead Offset* — Lead centerlines must be aligned to within 0.015" (0.381 mm) relative to the position of the leads on the opposite side of the package.

7.3.2.3 *Lead-to-Lead Alignment* — 0.010" ± 0.010" (0.254 mm ± 0.254 mm) measured at the base of the ceramic on the same side.

8 Sampling

Sampling sizes must meet the requirements of MIL-STD-105; although single, double, or multiple samples may be used.

9 Test Methods

9.1 *Mechanical, Electrical and Thermal Test Methods*

9.1.1 *Gold Plating Quality*

9.1.1.1 Purity and adhesion of the gold plated package shall be tested by placing parts on a calibrated heater block at:

Condition A — 450°C ± 10°C for two minutes in air, or

Condition B — 470°C ± 10°C for one minute in nitrogen.

9.1.1.2 After cooling at room temperature the packages will be visually examined for the following criteria:

9.1.1.2.1 Blisters on the leadframe are acceptable only on the tie bar (that portion removed during trim). Blisters on the bonding fingers shall not exceed 0.003" (0.076 mm) diameter with a maximum of 1 blister per finger and 5 blisters per package of any size. Blisters on the seal ring shall not exceed 0.005" (0.127 mm) diameter. Blisters on the die attach pad shall not exceed 0.010" (0.254 mm) diameter with a maximum of 5 blisters per package greater than 0.005" (0.127 mm) diameter.

9.1.1.2.2 Slight discoloration of the gold at the die attach pad edges up to 0.025" (0.635 mm) from the cavity walls is acceptable. Discoloration of the bonding fingers, seal ring surface or external leads is not acceptable.

9.1.1.2.3 There shall be no flaking or peeling of the package plating when viewed at 15× magnification.

9.1.1.2.4 Superficial stains left during drying or prior operations is not cause for rejection.

9.1.2 *Lead Pull* — Four pounds (1.8 kg) minimum at a 45° angle from the lead's original plane.

9.1.3 *Lead Fatigue* — Test per MIL-STD-883, Method 2004.2, Test Condition B2, Section 3.2.

9.1.4 *Thermal Characteristics* — Test per MIL-STD-883, Method 1012, Test Conditions A, B, C, D, and E.

9.2 *Functional Test Methods*

9.2.1 *Die Attach Quality* — Perform destructive die shear test post environmental testing per MIL-STD-883, Method 2019.1, Section 3.2C.

9.2.2 *Wire Bond Quality* — Perform minimum pre-seal and post-seal bond strength test per MIL-STD-883, Method 2011.2, Test Condition D. Reject for bonds which cause plating to lift from the base metal of the die attach surface or bonding fingers.

9.2.3 *Solderability* — Test per MIL-STD-883, Method 2003.2.

9.2.4 *Insulation Resistance* — Test per MIL-STD-883, Method 1003.

9.2.5 *Hermetic and Environmental Testing*

9.2.5.1 The hermetic integrity of the package must be maintained after all environmental testing. Hermetic checks shall comply with MIL-STD-883, Method 1014.3, Test Condition A_1 or B and C.

9.2.5.2 Environmental testing shall include, but not be limited to, the following:

1. *Temperature Cycle* — MIL-STD-883, Method 1010.2 Condition C
2. *Thermal Shock* — MIL-STD-883, Method 1011.2, Condition C

3. *Centrifuge* — MIL-STD-883, Method 2001.2, Condition E
4. *Mechanical Shock* — MIL-STD-883, Method 2002.2, Condition B

9.2.6 *Sequence of Events and Incoming Testing* — During incoming inspection the sequence of testing shall be:

1. Die Attach
2. Wire Bond
3. Pre-Seal Bond Pull
4. Seal
5. Environmental Test
6. Fine Leak
7. Gross Leak
8. Trim
9. Post-Seal Bond Pull
10. Radiography
11. Die Shear
12. Solderability

NOTE: An initial vendor qualification on the thermal and electrical characteristics of the package may be performed. The characteristics tested will be:

1. *Insulation Resistance* — MIL-STD-883, Method 1003, Test Condition D
2. *Thermal Dissipation* — MIL-STD-883, Method 1012

10 Packaging and Marking

10.1 *Packaging* — Containers selected shall be strong enough and suitably designed to provide maximum protection against crushing, spillage, and other forms of damage to the container or its contents. Containers shall afford protection of the contents to contamination from exposure to excessive moisture or oxidation by gases. Packaging materials shall be so selected to prevent any contamination of the ceramic component parts with paper fibers or organic particles.

10.2 *Marking* — The outer containers shall be clearly marked to identify the user stock number, user purchase order number, drawing number, quantity, and vendor lot number.

11 Product Design

11.1 *Leadframe Paddle Width and Standoff* — (See Figure 5.)

NOTE: A geometric symbol adjacent to an identifying lead number 1 shall be considered appropriate for packages with all leads isolated from the die attach.

NOTE: Lead number 14 is common to die attach surface and is identified by placing this number where lead number 1 is located.

11.1.1 Leadframe paddle width shall be 1.14 mm (0.045") ± 0.178 mm (0.007").

11.1.2 Standoff shall be 1.02 mm ± 0.254 mm (0.040" ± 0.010").

11.1.3 Hole Diameter shall be 0.032" – 0.033" (0.813 mm – 0.838 mm).

11.2 *Substrate/Terminal Commonality on Sidebrazed Laminate Packages* — If no leads are common to the die attach surface, the lead one identification shall be a geometric symbol (Figure 6).

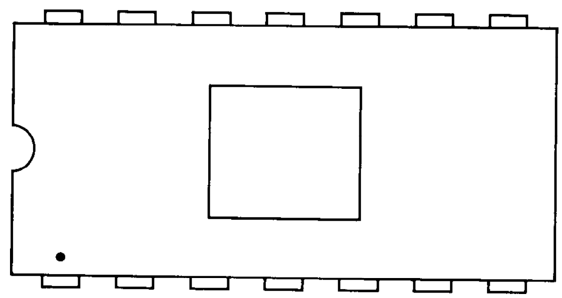


Figure 6
Lead Identification

Layers shall be designated by letter beginning with “A” as that layer nearest terminal insertion plane. Layers, regardless of function, shall be designated by succeeding letters, (B, C, D, etc.) as being progressively remote from the terminal insertion plane.

Should any lead be common to the die attach surface, that lead number will serve both as lead one identificationand as an indicator as to the lead that is common to the die attach surface (Figure 7).

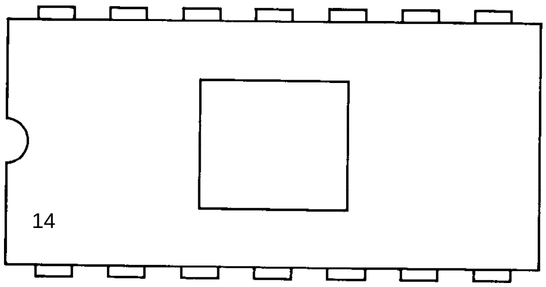

Figure 7
Lead Identification

11.3 *Sidebraze Ceramic Package Layer Design* — (See Figure 8).

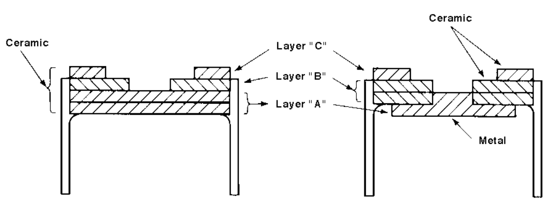

Figure 8
Layer Designation

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI G4-0302
SPECIFICATION FOR INTEGRATED CIRCUIT LEADFRAME MATERIALS USED IN THE PRODUCTION OF STAMPED LEADFRAMES

This specification was technically approved by the Gobal Assembly and Packaging Committtee and is the direct responsibility of the Japanese Assembly and Packaging Committee. Current edition approved by the Japanese Regional Standards Committtee on November 26, 2001. Initially available at www.semi.org December 2001; to be published March 2002. Originally published in 1994.

1 Scope

1.1 This specification covers the special requirements for a metal strip to be used to fabricate integrated circuit leadframes by stamping.

2 Applicable Documents

Regional standards such as ANSI/ASTM,CEN, EN ISO, JIS, and MIL.

2.1 *ANSI*[1]*/ASTMStandard*[2]

ASTM B 193 — Test Method for Resistivity of Electrical Conductor Materials

ASTM B 601 — Standard Practice for Temper Designations for Copper and Copper Alloys — Wrought and Cast

ASTM E 8 — Standard Test Methods of Tension Testing of Metallic Materials

ASTM E 228 — Standard Test Method for Linear Thermal Expansion of Solid Materials with a Vitreous Silica Delatometer

ASTM E 290 — Test Method for Semi-Guided Bend Test for Ductility of Metallic Materials

ASTM E 384 — Test Method for Microhardness of Materials

ASTM E 527 — Practice for Numbering Metals and Alloys (UNS)

2.2 *CES Standard*

CES M0002-5 — Method of W-Bend Test for Metallic Materials

2.3 *EN Standard*

EN 10 002 Part 1 — Metallic Materials, Tensile Testing, Part 1: Method of Testing (at ambient temperature)

EN 133/10 — Copper and Copper Alloys: Plate, Sheet, Strip, and Circles for General Purposes

EN 133/12 — Copper and Copper Alloys: Plate, Sheet, and Circles for Boilers, Pressure Vessels, and Hot Water Storage Units

2.4 *ISO Standard*[3]

ISO 197-3 — Copper and Copper Alloys, Terms, and Definitions, Part 3: Wrought Products

ISO 1190 Part 1 — Copper and Copper Alloys, Code of Designation, Part 1: Designation of Materials

ISO 4287 Part 1 — Surface Roughness, Terminology, Part 1: Surface and Its Parameters Trilingual Edition

ISO 6507 Part 1 — Metallic Materials, Hardness Test, Vickers Test, Part 1: HV 5 to HV 100

ISO 6507 Part 2 — Metallic Materials, Hardness Test, Vickers Test, Part 2: HV 0.2 to less than HV 5.

ISO 7438 — Metallic Materials, Bend Test

2.5 *JIS Standard*[4]

JIS B0601 — Definitions and Designation of Surface Roughness

JIS H0505 — Measuring Methods for Electrical Resistivity and Conductivity of Non-Ferrous Materials

JIS H3100 — Copper and Copper Alloy: Plates, Sheets, Strips

JIS H3110 — Phosphor Bronze and Nickel Silver: Plates, Sheets, Strips

JIS Z2201 — Test Pieces for Tensile Test for Metallic Materials

JIS Z2241 — Method of Tensile Test for Metallic Materials

JIS Z2244 — Method of Vickers Hardness Test

1 ANSI, 1430 Broadway, New York, NY 10018

2 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohoken, PA 19428-2959

3 ISO, 1 rue de Varembe, Case postale 56, CH01211 Geneva 20, Switzerland

4 JIS, 4-1-24 Akasaka Minato-ku Tokyo, Japan

JIS Z2251 — Method of Micro Hardness Test for Vickers and Knoop Hardness

3 Ordering Information

Orders for material under this specification shall include the following information:

1. Quantity of each size
2. Alloy name and number (see Section 4)
3. Temper or mechanical properties (see Section 4)
4. Dimensions: thickness and width (see Section 5)
5. How furnished: coils and coil size (see Section 10)
6. Special processing requirements
7. Certification or test report requirements (see Section 11).

4 Designations

4.1 Material designations shall be based on appropriate area standards based on country or area of material origin.

4.1.1 Europe ISO 1190 Part 1

4.1.2 Japan JIS H3100, JIS H3110

4.1.3 United States ASTM E 5.27

4.2 Temper designations shall be based on appropriate area standards based on country or area of material origin.

4.2.1 Europe EN133/10 and 133/12

4.2.2 Japan JIS H3100, JIS H 3110

4.2.3 United States ASTM B 601

5 Requirements

5.1 *General Requirements*

5.1.1 The materials covered by this specification shall conform to the requirements detailed herein, unless otherwise agreed upon by supplier and purchaser.

5.2 *Mechanical Properties*

5.2.1 The preferred method of designating mechanical properties of material covered under this specification is tensile strength. In addition to tensile strength, the 0.2% offset yield strength and percent elongation in 50 mm may be required if agreed between supplier and purchaser. The test shall conform to the appropriate area standards based on country or area of material origin.

5.2.1.1 Europe EN10 002 Part 1

5.2.1.2 Japan JIS Z2201, Z2241

5.2.1.3 United States ASTM E8

5.2.2 Should supplier and purchaser agree, microhardness may be used in lieu of tensile strength as the test for mechanical property. The test shall conform to the appropriate area standard based on country or area of material origin.

5.2.2.1 Europe ISO 6507 Part 1 and Part 2

5.2.2.2 Japan JIS Z2251, Z2244 (Test load shall be chosen from Table 1).

5.2.2.3 United States ASTM E 384

Table 1

Thickness of Metal Strip (mm)	*Test Load of Vickers Hardness*
0.100 to 0.160	1.961 N (200 gf)
over 0.160 to 0.500	4.903 N (500 gf)
over 0.500	9.807 N (1 Kgf)

5.3 *Thickness and Width Tolerance*

5.3.1 Thickness tolerance for material covered under this specification shall be chosen from Tables 2 and 3.

Table 2

Thickness	*Tolerance*
0.10 mm to 0.15 mm	± 0.005 mm
over 0.15 mm to 2.0 mm	± 3% of the ordered material thickness

Table 3

Thickness	*Tolerance*
0.10 mm up to 0.15 mm	± 0.005 mm
0.15 mm up to 0.3 mm	± 0.008 mm
0.3 mm up to 0.5 mm	± 0.010 mm
0.5 mm up to 0.8 mm	± 0.013 mm
0.8 mm up to 1.0 mm	± 0.015 mm
1.0 mm up to 1.5 mm	± 0.020 mm
1.5 mm up to 2.0 mm	±0.025 mm

* Table 3 is used in Europe.

5.3.2 Width tolerance shall be as shown in Tables 4 and 5.

Table 4

Width	*Thickness*	*Tolerance*
under 15 mm to 55 mm	0.1 mm to under 0.3 mm	± 0.05 mm
	0.3 mm to under 1.0 mm	± 0.08 mm
	1.0 mm to 2.0 mm	± 0.15 mm
over 55 mm to 100 mm	0.1 mm to under 0.3 mm	± 0.08 mm
	0.3 mm to under 1.0 mm	± 0.12 mm
	1.0 mm to 2.0 mm	± 0.15 mm

Table 5

Width	*Thickness*	*Tolerance*
under 15 mm	over 0.1 mm to 0.3 mm	± 0.05 mm
	over 0.3 mm to 1.0 mm	± 0.08 mm
	over 1.0 mm to 2.0 mm	± 0.15 mm
15 mm to 55 mm	over 0.1 mm to 0.3 mm	± 0.05 mm
	over 0.3 mm to 1.0 mm	± 0.08 mm
	over 1.0 mm to 2.0 mm	± 0.15 mm
Over 55 mm to 100 mm	over 0.1 mm to 0.3 mm	± 0.08 mm
	over 0.3 mm to 1.0 mm	± 0.12 mm
	over 1.0 mm to 2.0 mm	± 0.15 mm

* Table 5 is used in Europe.

5.4 *Surface Finish*

5.4.1 The material shall be commercially free of surface imperfections such as pits, nicks, dents, gouges, scratches, laminations, or inclusions.

5.4.2 The surface roughness of both sides shall be measured perpendicular to the direction of rolling and indicated as the arithmetic average height (R_a) and the maximum peak-to-valley roughness height (R_{max}).

5.4.2.1 Measurement and designations of surface roughness shall conform to appropriate area standards based on country or area of material origin.

5.4.2.1.1 Europe ISO 4287 Part 1

5.4.2.1.2 Japan JIS B0601

5.4.2.1.3 United States ANSI/ASME B46.1

5.4.2.2 Conditions for the measurement are shown in Table 6.

Table 6

Radius of Diamond Stylus: Less than 5mm	*(Record Actual Size)*
Cut Off:	0.8 mm
Stroke:	4 mm

5.4.2.3 Maximum acceptable values for surface roughness are shown in Table 7.

Table 7

Thickness	R_a	R_{max}
0.1 mm to under 0.3 mm	0.15 µm	1.0 µm (1.5 µm)
0.3 mm to 2 mm	0.20 µm	1.5 µm (2.0 µm)

* Values in parentheses are used in Europe.

5.5 *Camber (Edgewise Curvature)*

5.5.1 Camber is measured by placing a length of strip on a flat surface against the edge of a straight edge, as shown in Figure 1. The straight edge shall be of sufficient length to equal or exceed the length traditionally used in the area or country of origin of the material. The largest amount of separation of the strip sample from the straight edge shall be measured. Extreme care must be exercised with this test to ensure that the sample illustrates a uniform camber (no reverse curvature should be present in the sample), and also that it is not bent or kinked, as this could result in a grossly inaccurate measurement. The maximum camber per length allowable are shown in Table 8.

Table 8

Width	*Thickness*	*Max camber allowed in 1 meter*
Under 15 mm	0.1 mm to under 0.3 mm	1.8 mm (2.0 mm)
	0.3 mm to under 1.0 mm	2.2 mm (2.5 mm)
	1.0 mm to 2.0 mm	4.0 mm
15 mm to 55 mm	0.1 mm to under 0.3 mm	1.3 mm
	0.3 mm to under 1.0 mm	2.0 mm
	1.0 mm to 2.0 mm	3.0 mm
Over 55 mm to 100 mm	0.1 mm to under 0.3 mm	1.0 mm
	0.3 mm to under 1.0 mm	1.5 mm
	1.0 mm to 2.0 mm	2.5 mm

5.6 *Flatness*

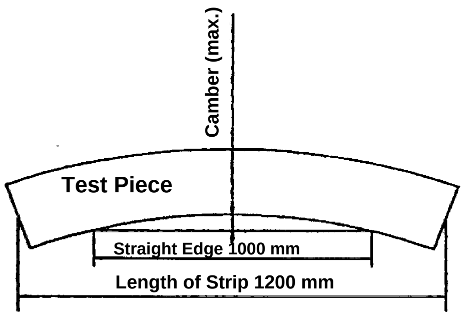

Figure 1
Camber

5.6.1 *Coil Set (Longitudinal Curl)*

5.6.1.1 Coil set shall be measured by attaching a length of strip, appropriate to the country or area of material origin, to a flat vertical surface as shown in Figure 2. The attachment shall be with a rigid block, wider than the strip. The block shall be so rigid as to ensure complete contact of the strip with the vertical surface. The distance between the flat surface and the free-hanging end of the strip (that is positioned for maximum distance from the flat vertical surface) shall be measured. The coil set shall be uniformly in the direction of coiling. Lengths shall be appropriate to the country or area of material origin. Maximum coil set for appropriate lengths are shown in Tables 9 and 10.

Table 9

Inside Diameter of Coil	*Thickness*	*Width*	*Max Coil Set in 1 m*
400 mm	under 0.3 mm	under 100 mm	100 mm

Table 10

Thickness	*Width*	*Max Coil Set in 0.3 m*
Under 0.3 mm	up to 15 mm	60 mm
	over 15 to 24 mm	50 mm
	over 24 to 55 mm	45 mm
	over 55 to 100 mm	40 mm
0.3 mm to 0.5 mm	up to 15 mm	70 mm
	over 15 to 24 mm	60 mm
	over 24 to 55 mm	55 mm
	over 55 to 100 mm	50 mm

* Table 10 is used in Europe.

5.6.2 *Crossbow (Dish)*

5.6.2.1 Crossbow shall be measured across the width of the strip, as shown in Figure 3. Burrs shall be removed or burr height excluded from this measurement. Crossbow shall be measured with a tool maker's microscope or equivalent. Crossbow maxima are listed in Tables 11 and 12.

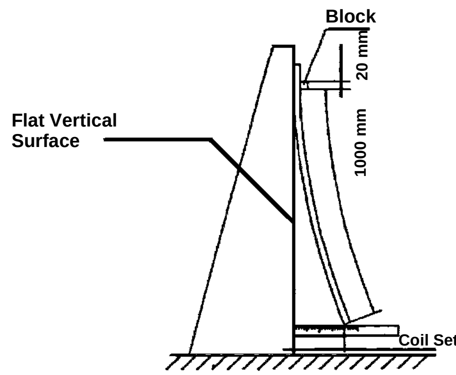

Figure 2
Coil Set

Table 11

Width	*Thickness*	*Crossbow Limit*
under 15 mm	0.1 mm to under 0.3 mm	0.5% of width
	0.3 mm to under 1.0 mm	1.0% of width
	1.0 mm to 2.0 mm	1.5% of width
15 mm to 55 mm	0.1 mm to under 0.3 mm	0.5% of width
	0.3 mm to under 1.0 mm	0.5% of width
	1.0 mm to 2.0 mm	0.5% of width
over 55 mm to 100 mm	0.1 mm to under 0.3 mm	0.4% of width
	0.3 mm to under 1.0 mm	0.4% of width
	1.0 mm to 2.0 mm	0.4% of width

Table 12

Width	*Thickness*	*Crossbow Limit*
from 15 mm to 24 mm	0.1 mm to under 0.3 mm	0.10 mm
	0.3 mm to under 1.0 mm	0.15 mm
	1.0 mm to 2.0 mm	0.20 mm
over 24 mm to 55 mm	0.1 mm to under 0.3 mm	0.15 mm
	0.3 mm to under 1.0 mm	0.20 mm
	1.0 mm to 2.0 mm	0.25 mm
over 55 mm to 100 mm	0.1 mm to under 0.3 mm	0.25 mm
	0.3 mm to under 1.0 mm	0.30 mm
	1.0 mm to 2.0 mm	0.35 mm

* Table 12 is used in Europe.

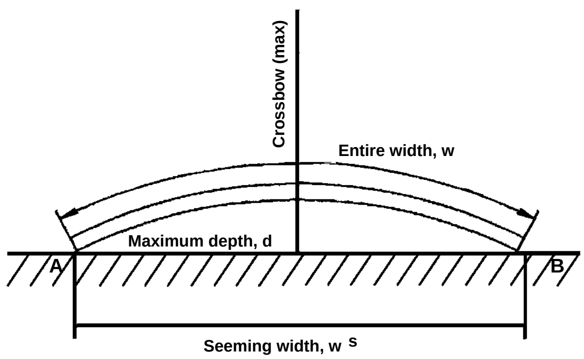

Figure 3
Crossbow

5.6.3 *Twist*

5.6.3.1 Twist shall be measured in a fashion similar to coil set, as shown in Figure 4A or Figure 4B. A length of strip, appropriate to the country or area of material origin, shall be attached at one end to a flat vertical surface. The attachment shall be with a rigid block, wider than the strip. The block shall be so rigid as to ensure complete contact of the strip with the vertical surface. At the free end of the strip, the distance from the vertical surface and both edges of the free strip end shall be measured. The maximum difference in these dimensions is shown in Table 13.

Table 13

Thickness	*Twist Maximum (Difference in Edge Distance)*
0.1 mm to 0.5 mm	Width × 0.2823 for 1000mm (Width × 0.2823 for 300mm)

* Value in parentheses is used in Europe.

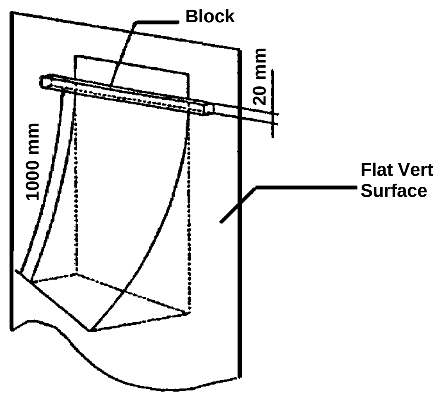

Figure 4
Twist Test

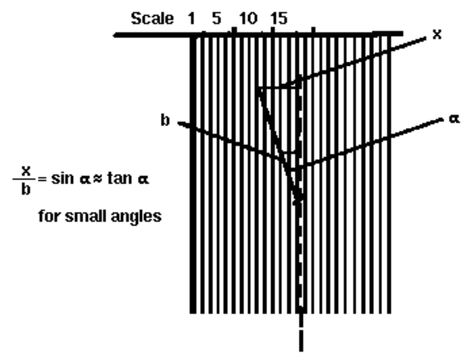

Figure 4B
Twist Test

5.7 *Burrs*

5.7.1 Edge burrs shall not exceed the values in Table 14 and 15. As shown in Figure 5, a-b shall be measured.

Table 14

Thickness	*Maximum Allowed Edge Burr*
0.1 mm to under 0.3 mm	Thickness x 10%
0.3 mm to under 1.0 mm	Thickness x 7%
1.0 mm to under 2.0 mm	Thickness x 5%

Table 15

Thickness	*Maximum Allowed Edge Burr Height*
0.1 mm to 0.3 mm	0.02 mm
Over 0.3 mm to 1.0 mm	0.03 mm
Over 1.0 mm to 2.0 mm	0.04 mm

* Table 15 is used in Europe.

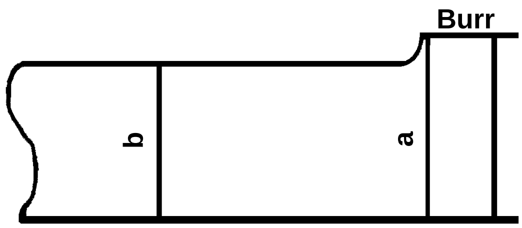

Figure 5
Burr

5.8 *Corrosion*

5.8.1 Visual inspection shall be performed within 60 days of receipt of material. The material shall be free of objectionable surface oxides which would render the product unusable for the intended application. The material shall have been stored for this period in the original supplier's package.

6 Bend Formability

6.1 When agreed between supplier and purchaser, a bend formability test shall be performed. This test shall be based on area standards based on country or area of material origin.

6.1.1 *Europe ISO 7438* — (Test jig is shown in Figure 2 of ISO 7438.)

6.1.2 *Japan CES M0002-5* — The test piece which shall be 10 mm wide and a minimum of 30 mm long will be put on the B type test jig with a bend radial of 0.15 mm and 0.25 mm and from 0–2.0 mm at interval of 0.2 mm. In this case, die pressure shall be 807N (1000Kgf) and over. The B type test jig is shown in Figure 2 of CES M0002-5.

6.1.3 *United States* — ASTM E 290.

7 Lead Bend Fatigue

7.1 When agreed between supplier and purchaser, a lead bend fatigue test shall be performed. This test shall be conform to the appropriate area standards based on the country or area of material origin.

7.1.1 *Europe* — MIL-STD-883.

7.1.2 *Japan* — Appendix 1

7.1.3 *United States* — MIL-STD-883.

8 Physical Properties

8.1 When agreed between supplier and purchaser, tests on physical properties shall be performed based on appropriate area standards based on country or area of material origin.

8.1.1 *Chemistry*

8.1.1.1 Chemical analysis of material shall be performed using accepted procedures such as X-Ray fluorescence spectroscopy, optical emission spectroscopy, and atomic absorption spectroscopy. These tests shall be performed based on appropriate area standards based on country or area of material origin.

8.1.1.1.1 *Europe* — ISO.

8.1.1.1.2 *Japan* — JIS.

8.1.1.1.3 *United States* — ASTM standards under preparation.

8.1.2 *Electrical Conductivity*

8.1.2.1 The test for electrical resistivity and conductivity shall be performed based on appropriate area standards based on country or area of material origin.

8.1.2.1.1 *Europe* — ASTM B193.

8.1.2.1.2 *Japan* — JIS H0505.

8.1.2.1.3 *United States* — ASTM B193.

8.1.2.2 Thermal conductivity shall be calculated from electrical conductivity using the law of Wiedemann and Franz, which is described as:

$k/\sigma T = L$, where:

k = thermal conductivity
σ = electrical conductivity
T = absolute temperature
L = Lorenz number = $2.44 \times 10^{-8} (V/K)^2$
where : V = voltage and K = Kelvin scale

8.1.3 *Coefficient of Thermal Expansion*

8.1.3.1 T he coefficient of thermal expansion shall be measured between 20°C and 300°C. The test shall be based on the appropriate area standard based on the country or area of material origin.

8.1.3.1.1 *Europe* — ASTM E 228.

8.1.3.1.2 *Japan* — ASTM E 228.

8.1.3.1.3 *United States* — ASTM E 228.

9 Silt Strain (Stress)

9.1 When agreed upon between supplier and purchaser, a test to determine internal stress distribution shall be performed. The test should be based on some form of chemical milling, sawing, or wire cutting to remove portions of the strip to form a pattern in the strip. As a guide to preparation of such tests, a procedure is shown in Appendix 2 or 3.

10 Coils

10.1 Unless otherwise specified, coils shall be supplied with an inside diameter that provides for good packing practice without resulting in excessive coil set.

10.2 All coils supplied shall be continuous, uniform lengths, and free of welds. Autogenous welds made at heavy gauge, prior to finish reductions that ultimately provide homogeneous structures, are allowed.

11 Certification or Test Reports

11.1 Requests for certifications or test reports shall be made at the time of order entry or contract agreement. They shall be furnished by the manufacturer within one week of date of shipment.

11.2 When certifications are required, the following information shall be supplied as a minimum:

1. Vendor name
2. Purchase order number
3. Vendor order number
4. Alloy name and number
5. Chemical analysis
6. Temper designation, reference only (for copper base alloys only)
7. Tensile strength
8. Elongation percent in 50 mm
9. Electrical conductivity % IACS (for copper base alloys only)

11.3 In the event of a disagreement between supplier and purchaser, an independent test shall be conducted on strip to verify the data provided in the certification.

12 Packaging and Marking

12.1 The material shall be separated by size, composition, and temper, and prepared for shipment in such a manner as to ensure acceptance by a common carrier for transportation at the lowest applicable rate.

12.2 The material shall be suitably packaged to protect from condensation, contamination, etc., and to afford protection from the normal hazards of transportation.

12.3 Each shipping unit shall be legibly marked with the purchase order number, alloy name or number, temper, size, gross and net weight, and name of the supplier. The specification number shall be shown when specified on the purchase order.

12.4 Any special packaging or shipping requirements shall be agreed upon between supplier and purchaser at the time of purchase.

13 Basis for Rejection

13.1 For the purposes of determining conformance with the requirements prescribed in the specifications, any measured value outside the specified limiting values shall be cause for rejection.

13.2 If objectionable material is found and rejected, samples of the questionable material, with the defects identified and marked, should be sent to the supplier along with information as to order number, quantity originally received, date received, and quantity rejected. Rejected material should be held with adequate protection and identification by the purchaser for a reasonable amount of time, pending investigation by the supplier.

APPENDIX 1
TEST METHOD FOR LEAD BEND FATIGUE OF METAL STRIPS

NOTE: The material in this appendix is an official part of SEMI G4.

A1-1 Preface

This is related to the test method for lead bend fatigue of metal strips of leadframe materials improving MIL-STD-883. Results of this test suggest the lead bend fatigue resistance of leadframes.

The following method is set up especially for the strips with the thickness of 0.25 mm ± 0.008 mm.

A1-2 Method of Measurement

A1-2.1 *Equipment* — Automatic or manual lead bend fatigue tester as shown in Figure A1-1.

A1-2.2 *Preparation of Specimen* — The specimen with the width of 0.5 mm ± 0.05 mm is made by either etching or stamping method. A wider portion on one end is recommended for a good grip as shown in Figure A1-2.

A1-2.3 *Procedure* — The specimen is clamped on both ends with clamp and weight as shown in Figure A1-3 and tested under the conditions listed in Table A1-1. The number of bending cycles (*) and other information (**) should be recorded.

*The number of bending cycles: The cycles until specimen breaks, and weight drops into pan.

0° – 90° – 0° bend on one side is counted as 1 cycle.

0° – 90° is counted as 0.5 cycle.

**Other information:

1. Rolling direction on the specimen.
2. Actually measured dimensional data of thickness and width.
3. Burr side related to bending corner (for stamped specimen only).

APPENDIX 2
TEST METHOD FOR SLITTER STRAIN OF STRIPS USED FOR LEADFRAME STAMPING

NOTE: The material in this appendix is an official part of SEMI G4.

A2-1 Preface

This is related to the general evaluation method for slitter strain of strips used for leadframe stamping. Such distortion could result in adverse effects on leadframes, such as coil set, lead twist, and camber.

A2-2 Evaluation Method

A2-2.1 *Equipment* — Tool microscope (×100).

A2-2.2 *Procedure*

A2-2.2.1 Collect flat samples approximately 150 mm in length from strips in a way that residual distortion can be overlooked. (Collection methods include wire cutting, etching, refined cutting, etc.) Thickness of samples should be either 0.25 mm, 0.20 mm, or 0.15 mm.

A2-2.2.2 Fashion each sample to the shape shown in Figure A2-1 by etching or wire cutting. Measure with the tool microscope to obtain coordinates of the leg end corner. The reading accuracy is to 0.1 mm (see Note 1).

A2-2.2.3 Using the coordinates of the leg end corner, for each leg obtain longitudinal curvature “A”, lead twist “B”, and camber “C”, as shown in Figure A2-2 (see Note 2).

Note 1: Specify the direction of slit burr, and for legs in which the longitudinal curvature A is reversed, measure by reversing the sample itself.

Note 2: Measured values are marked as shown in Figure A2-2.

Note 3: This method should be applied to only slitter strain. Do not apply to any other kind of strain (e.g., thermal inner strain).

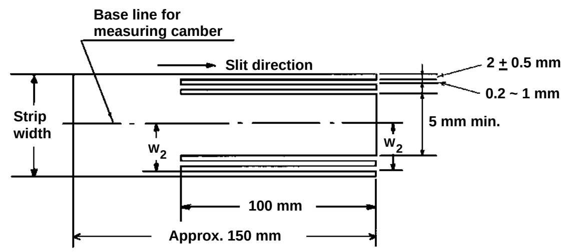

Figure A2-1
Shape for Evaluation of Slitter Strain

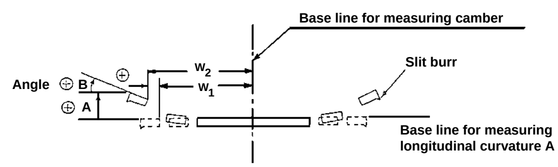

Figure A2-2
Evaluation Items

APPENDIX 3
TEST METHOD FOR SLIT STRAIN OF LEADFRAME STRIPS USED FOR STAMPING

NOTE: The material in this appendix is an official part of SEMI G4.

A3-1 Preface

A3-1.1 The method is used to evaluate the edge stress caused by slitting.

A3-1.2 This method is applied to thickness between 0.1 mm and 0.3 mm.

A3-2 Evaluation Method

A3-2.1 *Equipment* — Tool microscope (×100).

A3-2.2 *Procedure*

A3-2.2.1 A test piece of approximately 200 mm length is sawn, stamped, etched, wire cut, refined cut, etc., over a length of 100–150 mm parallel to the rolling direction of a distance of 2–5 mm from the edge of the strip. (See Figure A1-7.)

A3-2.2.2 The dislocation of the outer strips relative to the plane of the test piece measured as camber c, longitudinal curvature L, and twist T characterize the internal edge stress. (Note 1)

Note 1: The details of the test method and the maximum admissible values of c, L, and T shall be agreed between purchaser and supplier.

Test Method of Slit Stress

SEMI G5-87
STANDARD FOR CERAMIC CHIP CARRIERS

1 Scope

This specification defines the acceptance criteria for co-fired, ceramic chip carriers both leaded and lead-less.

2 Applicable Documents

2.1 *ANSI Specification*[1]

S Y 14.5 — Dimensioning and Tolerancing

2.2 *Federal Specification*[2]

QQ-N-290 — Nickel Plating

2.3 *JEDEC Specification*[3]

Pub. No. 95 — Registered and Standard Outline for Solid State Products

2.4 *Military Specifications*[4]

MIL-STD-105 — Sampling Procedures and Tables for Inspection by Attributes

MIL-STD-883 — Test Methods and Procedures for Microelectronics

MIL-STD-7883 — Brazing

MIL-M-38510 — General Specification for Microcircuits

MIL-STD-45204 — Gold Plating, Electrodeposited

2.5 *SEMI Specifications*

SEMI G8 — Test Method for Gold Plating Quality

SEMI G25 — Test Method for Measuring the Resistance of Package Leads

SEMI G6 — Test Method for Seal Ring Flatness

3 Selected Definitions

braze — An alloy with a melting point equal to or greater than 600°C.

castellation — That series of ribs and metallized indentations that define edge contact regions (see Figure 1).

fired — A process or technology to manufacture products in which the ceramic and refractory metallization are fired simultaneously.

contact pad — That metallized pattern that provides mechanical or electrical connection to the external circuitry.

die attach surface — See Figure 3.

footprint — Contact pad pattern.

layer — A dielectric sheet with or without metallization that performs a discrete function as a part of the package.

lead offset — Alignment of leads across the package.

pullback — The linear distance between the edge of the ceramic and the first measurable metallization and/or glass interface (see Figures 4 and 5).

rundown — See Figures 4 and 5.

seal-area — A dimensional outline area designated for either metallization or bare ceramic to provide a surface area for sealing (see Figure 3).

terminal — Case outline at point of entry or exit of an electrical contact.

TIR — Total Indicator Reading.

4 Ordering Information

Purchase order for ceramic chip carriers furnished to this specification shall include the following items:

1. Quantity
2. Drawing — The drawing(s) for ceramic chip carriers shall specify the following information:
   a. Drawing number and revision level.
   b. Number of terminals and terminal center line spacing.
   c. Lead material and dimensions.
   d. Critical material properties.
   e. Type and thickness of plating.
   f. Package dimensions per ANSI Y14.5.
   g. Internal bonding patterns.
   h. Minimum exposed metallized bond finger length and width.

1 ANSI, 1430 Broadway, New York, NY 10018

2 Military Standards, Naval Publications and Form Center, 5801 Tabor Ave., Philadelphia, PA 19120

3 JEDEC, 2001 Eye Street, N.W., Washington, D.C. 20006

4 General Services Administrator, 4th and D Streets, SW, Room 6039, Washington, D.C. 20407

i. Portion of external footprints connected to die attach area and/or seal ring.

j. Terminal #1 position, internal and external.

k. Certification (optional).

l. Method of test and measurements.

m. Electrical, mechanical, environmental requirements.

3. Reference to this specification

4. Any exception to print or specification

5 Dimensions and Permissible Variations

5.1 The dimensions of ceramic chip carriers shall conform to those specified in the customer drawing, and be within the outline of JEDEC Publication No. 95.

NOTE: A dimensioning scheme and measurement fixture are under task force review.

5.2 *Critical Material Parameters*

5.2.1 *Ceramic*

5.2.1.1 Alumina, content 90% minimum.

5.2.1.2 *Color* — Dark or white.

5.2.2 *Metallization*

5.2.2.1 Refractory metallization.

5.2.2.2 Plating (if designated) per MIL-M-38510.

5.2.2.3 Nickel per QQ-N-290

5.2.2.4 Gold per MIL-STD-45204, Type III.

5.2.2.5 Gold Plating Quality see SEMI G8.

5.2.3 Braze per MIL-STD-7883.

5.2.4 Lead per MIL-STD-23011.

5.2.4.1 Iron Nickel Cobalt alloy per MIL-M-38510, Type A.

5.2.4.2 Iron Nickel alloy per MIL-M-38510, Type B.

6 Functional Testing

The following tests are recommended for functional evaluation of ceramic chip carriers. (The conditions of acceptance to be negotiated between the customer and the vendor.)

6.1 *Die Attach*

6.2 *Pre-Seal Die Shear* — (See Section 10.1.6.)

6.3 *Wire Bond*

6.4 *Pre-Seal Bond Pull* — (See Section 10.1.7.)

6.5 *Seal*

6.6 *Environmental Test* — (See Sections 10.1.1 through 10.1.13.)

6.7 *Hermeticity* — (See Section 10.1.14) Lid Torque or Shear (for glass seal parts).

6.8 *Post-Seal Bond Pull* — (See Section 10.1.7.)

6.9 *Post-Seal Die Shear* — (See Section 10.1.6.)

7 Incoming Testing

7.1 *Visual* — (See Section 8.)

7.2 *Dimensions*

7.3 *Functional* — (See Section 6.)

7.4 *Standard Tests*

7.4.1 *Electrical* — (See SEMI G25.)

7.4.2 *Gold Plating Quality* — (See SEMI G8.)

7.4.3 *Trim*

7.4.4 *Lead Integrity* —(See Section 10.1.15.)

7.4.5 *Solderability* — (See Section 10.1.16.)

8 Visual

8.1 *Applicable Definitions*

blister (bubble) ceramic — Any separation within the ceramic which does not expose underlying ceramic material.

blister (bubble) metal — Any localized separation within the metallization or between the metallization and ceramic which does not expose underlying metal or ceramic material.

burr — An adherent fragment of excess parent material at the component edge.

chip — A region of ceramic missing from the surface or edge of a package which does not go completely through the package. Chip size is given by its length, width, and depth from a projection of the design plan-form (see Figure 2).

crack — A cleavage or fracture, internal or external.

die attach surface — See Figure 3.

discoloration — Any non-uniform color change of the package plating.

foreign material — An adherent particle other than parent material of that component.

LSI — Large scale integration.

void, dielectric — An absence of screen printed ceramic from a designated area greater than 0.76 mm (0.003") in diameter.

void, metallization — An absence of refractory metallization, braze, or plating material from a designated area greater than 0.076 mm (0.003") in diameter.

8.2 *Visual Criteria* — (10× magnification) (See Section 8.1.)

8.2.1 *Ceramic* — Unmetallized Surfaces

8.2.1.1 *Cracks* — None allowed per MIL-M-38510, Method 1014.

8.2.2 *Chips*

8.2.2.1 *Corner* — 0.762 mm (0.030") × 0.762 mm (0.030") × one tape layer thickness, maximum.

8.2.2.2 *Edge* — 2.54 mm (0.100") × 0.762 mm (0.030") × one tape layer thickness, maximum.

8.2.2.3 Chips cannot encroach upon seal area, or contact pad, or expose any buried metallization.

8.2.3 *Burrs, Projections, and Blisters*

8.2.3.1 *Top Plane, Excluding Seal Area* — 0.102 mm (0.004") maximum.

8.2.3.2 *Seal Area* — 0.025 mm (0.001") maximum.

8.2.3.3 *Heat Exchanger Attach Area* — 0.076 mm (0.003") maximum (if designated).

8.2.3.4 *Contact Surface* — 0.051 mm (0.002") maximum.

8.2.3.5 *Edges* — 0.152 mm (0.006")

8.2.3.6 Burrs, projections, and blisters must fit within the outline tolerances.

8.2.4 *Camber* — Ceramic of 0.1 mm/25.4 mm (0.004 inch/inch), maximum. None to be specified less than 0.076 mm (0.003") along any planar dimension of the part.

8.2.5 *Flatness* — See table below:

Table 1 Flatness

Flatness: Seal Area: Seal Ring Size	*Flatness (TIR)*
0–6.35 mm (0"–0.250")	0.051 mm max. (0.002")
6.37–12.7 mm (0.251"–0.500")	0.076 mm max. (0.003")
12.72 –25.4 mm (0.501"–1.000")	0.101 mm max. (0.004")
25.42 mm and up (1.001")	0.004 in/in

8.3 *Ceramic Metallized Surfaces*

8.3.1 *Voids*

8.3.1.1 *Seal Area* — maximum of 3 voids permitted. No more than two voids per side of 0.010" diameter maximum each. Any two voids must be separated by 0.030" (0.762 mm) minimum, not to degrade the seal width by more than 25%.

8.3.1.2 *Footprint* — Two voids per pad 0.254 mm (0.010") diameter maximum. A contiguous path must never be reduced by more than 1/3 the minimum design width.

8.3.1.3 *Wire Bond Fingers* — A void-free area 0.254 mm (0.010") × 0.254 mm (0.010") or as defined by the customer drawing.

8.3.1.4 *Heat Exchange Attach Area* — (if designated) The major dimension of a void shall not exceed 0.508 mm (0.020") and all voids must be separated by 0.762 mm (0.030"). Total void area to be equal or less than 10%.

8.3.1.5 *Die Attach Surface* — Three voids of 0.010" diameter are the maximum allowed separated by 0.030" minimum.

NOTE: Voids within 0.015" of a cavity wall 0.381 mm are excluded from this requirement.

Table 2 Die Attach Area Flatness Limits

Die Attach Pad Dimension	*TIR Flatness*
0-12.7 mm (0–0.500")	0.51 mm (0.002" max.)
12.72–19.5 mm (0.501"–0.750")	0.088 mm (0.0035" max.)

8.3.1.6 *Internal Metallization* — Voids shall not break continuity between wire bond fingers and the corresponding contact pad. The user may specify additional resistance and capacitance parameters for each application.

8.3.2 *Burrs and Projections* — Shall not exceed the specification of Table 3.

Table 3 Maximum Height of Burrs and Projections

	Maximum Inches	*Height mm*
Wire Bond Finger Area	0.001	(0.025)
Seal Area	0.001	(0.025)
Die Attach Surface	0.001	(0.025)
Contact Pad	0.002	(0.051)
Heat Exchanger Attach Area	0.003	(0.076)

8.3.3 Pattern Definitions (Cavity Packages) — (See Figure 4.)

8.3.3.1 *Seal Plane Rundown* — internal cavity — Not to exceed 25% of the cavity layer thickness.

8.3.3.2 *External to the Cavity* — Separation shall not be less than 0.254 mm (0.010") or 50% of the design width, whichever is less.

8.3.3.3 *Wire Bond Finger Pullback* — Not to exceed maximum from the cavity edge. The minimum exposed lead length must meet the dimension per applicable drawing.

8.3.3.4 *Wire Bond Finger Rundown* — Not to exceed 25% of the ceramic layer thickness or 0.127 mm (0.005"), whichever is smaller.

8.3.4 *Pattern Separation* — Minimum shall not be reduced by more than 50% of the design.

8.4 *Lead Attachment*

8.4.1 *Voids in Braze* — 66% of the braze fillet must be void-free.

8.4.2 *Lead Alignment* — Misalignment leads to braze pads — The leads shall not overhang braze pads.

8.4.2.1 *Lead Offset* — To be specified on user drawing. Lead center lines must be aligned to within .178 mm (.007").

8.4.2.2 *Lead-to-Lead Misalignment* — To exceed ± 10% of nominal lead spacing.

8.4.2.3 *Dimensional Criteria* — To be specified on user drawing.

9 Sampling

Sample sizes must meet requirements of MIL-STD-105 or MIL-M-38510 as agreed to between vendor and customer. Single, double, or multiple samples may be used.

10 Test Methods

10.1 *Mechanical, Electrical, and Thermal Test Methods* — Per MIL-STD-883, unless otherwise noted.

10.1.1 Gold plating thickness shall conform to MIL-STD-45204. Gold thickness may be determined using the Beta Backscatter Radiation Method or X-Ray Fluorescence.

10.1.2 Nickel plating shall conform to MIL-STD-45204. Nickel thickness may be determined using the Beta Backscatter Radiation Method.

10.1.3 *Seal Ring Flatness* — See SEMI G6.

10.1.4 *Electrical Trace Resistance* — See SEMI G25.

10.1.5 *Gold Plating Quality* — See SEMI G8.

10.1.6 *Die Shear* — Destructive — Method 2019.

10.1.7 *Wire Bond* — Method 2011, Condition D. Reject for bonds which cause plating to lift from the base metal of the die attach surface or bonding fingers.

10.1.8 *Temperature Cycle* — Method 1010, Condition C.

10.1.9 *Thermal Shock* — Method 1011, Condition C.

10.1.10 *Constant Acceleration* — Method 2001, Condition E.

10.1.11 *Mechanical Shock* — Method 2002, Condition B.

10.1.12 *Insulation Resistance* — Method 1003.

10.1.13 *Internal Water Vapor Content* — Method 1018.

10.1.14 *Hermeticity* — Method 1014, Conditions A, B, and C. The hermetic integrity of the package must be maintained after all environmental testing.

10.1.15 *Lead Integrity* — Method 2004, Condition B.

10.1.16 *Solderability* — 2003.

10.1.17 *Moisture Resistance Testing* — Method 1004.

11 Packaging and Marking

11.1 *Packaging* — Containers selected shall be strong enough, and suitably designed, to provide maximum protection against crushing, spillage, and other forms of damage to the container or its contents. Containers shall afford protection of the contents to contamination from exposure to excessive moisture or oxidation by gases. Packaging materials shall be so selected to prevent any contamination of the ceramic component parts with paper fibers or organic particles. Regardless of packaging, all parts should be cleaned before testing or use.

11.2 *Marking* — The outer containers shall be clearly marked identifying:

1. Vendor Part #
2. Customer Part #
3. Quantity
4. Date
5. Vendor Lot #
6. User P.O. number (optional)
7. Drawing number (optional)

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI G6-89
TEST METHOD FOR SEAL RING FLATNESS

1 Purpose

This specification covers the method for determining the maximum deviation between the seal ring and a reference plane defined by three fixed points on the seal ring. This method will not work on parts smaller than 0.330" × 0.330".

2 Equipment

2.1 Flat plate (black granite calibrated at ± 0.000025" (± 0.000835 mm) or equivalent).

2.2 *Fixture Clamps* — Three required (See Figure 1).

2.3 *Fixture Base* — (See Figure 1).

2.4 *Test Indicator* — (Hamilton Kwik Check or equivalent).

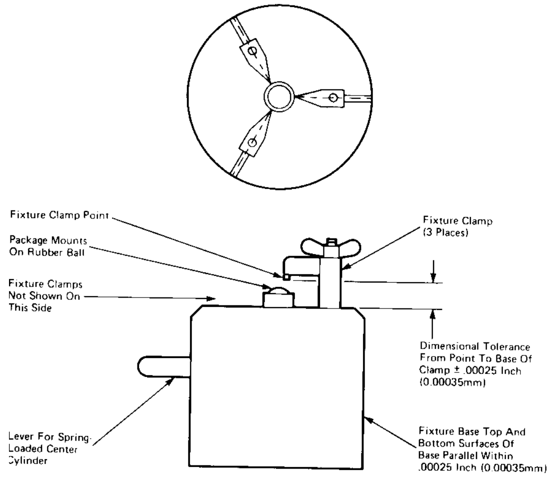

Figure 1
Fixture Base and Clamp Assembly

3 Preparation

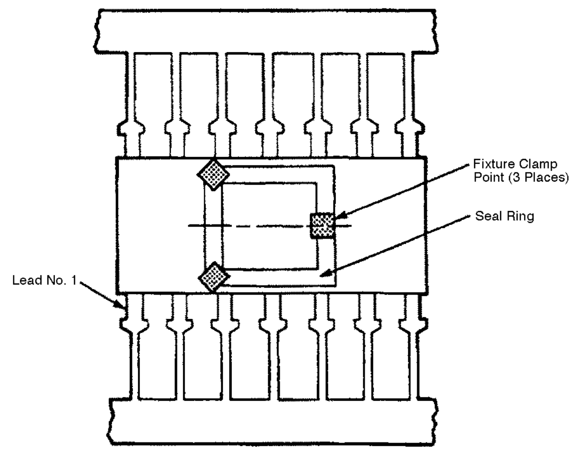
3.1 Fixture clamps shall be adjusted for part to be measured (see Figure 2).

3.2 The gaging fixture is to be calibrated with a precision ground gage block before each sample is measured.

3.2.1 Place gage block under the three fixture clamp points and release center cylinder to hold in place.

3.2.2 Position fixture base so the point of the test indicator is on the gage block.

3.2.3 Move fixture base so the point of the test indicator traverses the entire surface of the gage block. The total deviation read on the test indicator shall not exceed 0.0005" (0.013 mm).



Fixture clamp points aligned on seal ring diagonals on end closest to lead No. 1 and on ceramic center line opposite end.
Points aligned on diagonals shall not extend beyond the outside corners of the seal ring. Point aligned on the centerline shall not extend beyond the outside edge of the seal ring.

Figure 2
Fixture Clamp Orientation

4 Procedure

4.1 Place the package under the three fixture clamp points and release cylinder to hold in place (see Figure 2) for orientation of package seal ring and fixture clamp points.

4.2 Position fixture base so the point of the test indicator is on the package seal ring.

4.3 Move fixture base so the point of the test indicator traverses the length of the seal ring.

4.3.1 Move fixture base so the point of the test indicator stays in the middle of the seal ring.

4.3.2 Test indicator shall be relocated twice to get around fixture points.

5 Evaluation

If material buildup on the seal ring is visible with the unaided eye, the part shall not be used for this measurement.

SEMI G8-94
TEST METHOD FOR GOLD PLATING

1 Preface

1.1 *Purpose* — This test method describes procedures to determine gold plating quality.

1.2 *Scope* — These methods apply to gold plating on cofired ceramic or metal packages. The grade, hardness, and thickness of the gold plating shall be specified per MIL-G-45204 unless otherwise agreed between vendor and customer.

Note 1: The gold plate may be over refractory metal on cofired ceramic packages or over an underplate on metal packages.

2 Applicable Documents

2.1 *Referenced Documents*

2.1.1 *SEMI Specifications* — All SEMI package specifications

2.1.2 *ASTM Specifications*[1]

B 384 — Standard Test Method for Microhardness of Materials

B 487 — Test Method for Measurement of Metal and Oxide Coating Thicknesses by Microscopic Examination of a Cross-Section

B 567 — Method for Measurement of Coating Thickness by the Beta Backscatter Method

B 568 — Method for Measuring Coating Thickness by X-Ray Spectrometry

F 1269 — Test Methods for Destructive Shear Testing of Ball Bonds

2.1.3 *Military and Federal Specifications*[2]

MIL-STD-750 — Test Methods for Semiconductor Devices

MIL-STD-883 — Test Methods and Procedures for Microelectronics

MIL-G-45204 — Gold Plating, Electrodeposited

2.2 *Related Documents*

Military and Federal Specifications

MIL-STD-105 — Sampling Procedures and Tables for Inspection by Attributes

MIL-STD-202 — Test Methods for Electronic and Electrical Componenet Parts

MIL-STD-19500 — General Specification for Semicondutor Devices

MIL-M-38510 — General Specification for Microcircuits

3 Summary of Method

Various test methods are described or referenced to determine gold plating quality for the following items:

- Visual Appearance
- Plating Thickness
- Plating Adhesion
- Functional tests
- Salt Atmosphere
- Hardness

4 Significance and Use

4.1 *Significance* — Poorly plated components result in lowered yields during package assembly operations or to reliability problems.

4.2 *Use* — The methods described in this document may be used by vendors to test gold plated components as part of their process control program, or by customers at incoming inspections.

The methods are to used in conjunction with individual component specifications.

5 Terminology

5.1 *blister (metal)* — An enclosed, localized separation of a metallization layer from its base material (such as ceramic or another metal layer) that does not expose the underlying layer.

5.2 *discoloration* — The change in color of any plated metallization, gold, silver, aluminum, etc., as detected by the unaided eye after the application of heat to the metallization. The metallization may be over base metal, another plated layer, or on refractory metal.

5.3 *peeling (flaking)* — Any separation of the plated, vacuum deposited or clad metal from the base metal of a leadframe, lead, pin, heatsink, or seal ring, from an underplate, or from refractory metal on a ceramic package. Peeling exposes the underlying material. Also called flaking.

---

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohoken, PA 19428-2959

2 Military Standards, Naval Publications and Form Center, 5801 Tabor Avenue, Philadepphia, PA 19120

5.4 *pitting (plated metal layer)* — Unspecified depressions in the plated layer, not the underlying layer(s). Such pits may be caused by incorrect plating conditions.

5.5 *resin bleed-out (die attach)* — The surface creep of a resin used for die attach beyond the outer perimeter of the bulk of the resin (filler). For a given resin formulation, the resin creep may be exacerbated by the microstructure and cleanliness of the die attach surface.

5.6 *scratch* — An abrasion in the surface of a metallization layer which exposes the base material.

6 Interferences

6.1 Avoid contaminating the gold plated surface (e.g., with finger oils), prior to performing the tests. Such contamination may effect visual appearance, and die attach, wire bond, and solderability functional tests.

7 Equipment

7.1 Beta Backscatter system

7.2 Die Attach equipment

7.3 Eutectic Die Attach heater block or lot plate capable of 450 °C ± 10 °C.

7.4 Microscope 10-30× magnification with vertical lighting.

7.5 Micro Cross-Section equipment

7.6 Wire Bond equipment

7.7 X-Ray Fluorescence System

8 Sampling

8.1 Sampling plans shall be agreed between vendor and customer.

9 Test Sequence

When the test methods are used at incoming inspection the sequence of test shall be as follows:

9.1 *Visual Appearance* — See Section 10.1.

9.2 *Plating Thickness* — See Section 10.2.

9.3 *Plating Adhesion* — See Section 10.3.

9.4 *Functional Tests (Die Attach, Wire Bond, and Lead Solderability)* — See Section 10.4.

9.5 *Salt Atmosphere Test* — See Section 10.5.

9.6 *Plating Hardness* — See Section 10.6.

10 Test Procedures

10.1 *Visual Inspection*

10.1.1 Components shall be visually inspected according to the appropriate component specification for plating requirements.

10.1.2 *Surface Structure* — The gold plate shall be smooth matte to semi-bright in appearance. Minor variations in color are not cause for failure at this stage unless there is evidence of corrosion, peeling, or pitting in the plating layer.

Note 2: For the purposes of this test method, particular attention shall be observed in relation to blisters and adhesion problems with the plating layer.

10.2 *Plating Thickness*

10.2.1 Plating thickness shall be measured at locations agreed upon between vendor and customer.

10.2.2 Plating thickness may be measured by one of the following techniques, which are listed in order of preference.

ASTM Method B 568

ASTM Method B 567

ASTM Method B 487

Note 3: Method B 487 shall only be used for thicknesses greater than 100 microinches (0.0025 mm).

10.3 *Plating Adhesion*

10.3.1 Submit samples to 450 °C ± 10°C for two (2) minutes in air on a die attach heater block or hot plate.

10.3.2 Visually inspect the plating under the microscope set at 10× magnification for blistering, peeling, and discoloration.

Note 4: Discoloration after the heat testing is only allowable if the gold plate thickness is less than 20 micro-inches (508 micro mm) by design. Amount and type of discoloration shall be agreed upon between vendor and customer.

Note 5: 30× magnification may be used for confirmation.

10.3.3 *Adhesion Tape Test — Flat Surface*

10.3.3.1 Place a strip of tape across the plated area. Press firmly with finger tips or another smooth object.

10.3.3.2 Peel the tape quickly off the plated surface. If there is any plating on the tape the component shall be rejected.

10.3.4 *Lead Finish Adherence — Bend Test*

10.3.4.1 Bend the leads once through a 90° angle on a diameter equal to the lead diameter or thickness.

10.3.4.2 Visually inspect the plating under the microscope set at 10× magnification for evidence peeling or cracking of the plated layer.

10.4 *Functional Tests*

10.4.1 *Die Attach and Wire Bond*

10.4.1.1 Die Attach and Wire Bond tests shall be performed using materials and conditions agreed between vendor and customer.

10.4.1.2 Die Attach shall be evaluated for shear strength per MIL-STD-883, Method 2019 or by a method agreed between vendor and customer.

Resin bleed-out shall also be evaluated when the extent of the bleed may affect subsequent wire bonding processes.

10.4.2 *Solderability*

10.4.2.1 Solderability testing, with or without aging, shall be agreed between vendor and customer. Solderability testing shall be performed per MIL-STD-883, Method 2003.

10.5 *Salt Atmosphere Test*

10.5.1 *Salt Atmosphere Testing Requirements* — Applicability and condition shall be agreed between vendor and customer. Salt atmosphere testing shall be performed per MIL-STD-883, Method 1009 or MIL-STD-750, Method 1041 as appropriate.

10.6 *Plating Hardness*

10.6.1 If specified, the plating hardness shall be determined by one of the following methods as appropriate:

ASTM B 384

ASTM E 10

Note 6: Hardness testing for thin plating is difficult and not very reliable. The hardness specification shall be agreed between user and supplier.

SEMI G9-89
SPECIFICATION FOR STAMPED LEADFRAMES FOR PLASTIC MOLDED DUAL-IN-LINE SEMICONDUCTOR PACKAGES

1 Preface

This specification is a guideline for the stamping manufacture of leadframes for plastic molded dual-in-line semiconductor packages. It is a design guideline for packaging engineers, leadframe stampers and mold manufacturers, and has been developed to meet the requirements of automatic bonding.

2 Applicable Documents

2.1 This document specifically refers to:

SEMI G4 — Specification for Integrated Circuit Leadframe Materials Used in the Production of Stamped Leadframes

SEMI G10 — Standard Method of Mechanical Measurement

SEMI G21 — Specification for Plating Integrated Circuit Leadframes

2.2 Related information may also be found in:

MIL-STD-105[1] — Sampling Procedures and Tables for Inspection by Attributes

MIL-STD-883 — Test Methods and Procedures for Microelectronics

3 Selected Definitions

burr — A fragment of excess material either horizontal or vertical attached to the leadframe.

camber — Curvature of the leadframe strip edge (see Figure 1).

coil set — Longitudinal bowing of the leadframe strip length (see Figure 2).

coined area — Reference lead flat surface.

crossbow — Transverse bowing of the leadframe (see Figure 3.)

functional area — The die attach pad and the lead tips.

lead flat surface — Area on the lead tips that is suitable and available for wire bonding. This is generally achieved by coining on stamped leadframes and is also known as the coined area on such leadframes.

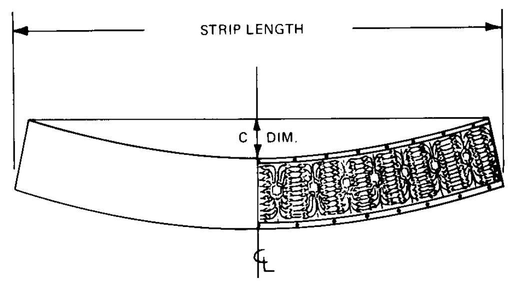


Figure 1
Camber

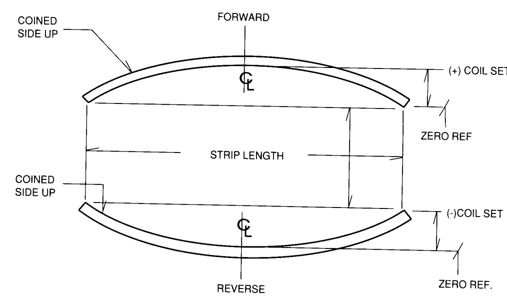

Figure 2
Coil Set

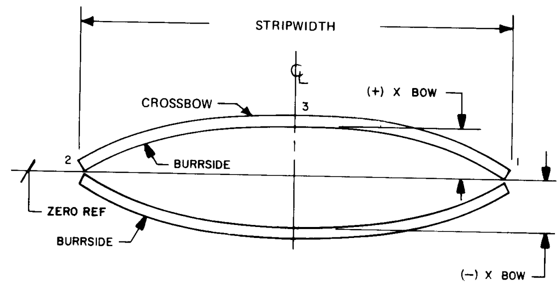

Figure 3
Crossbow

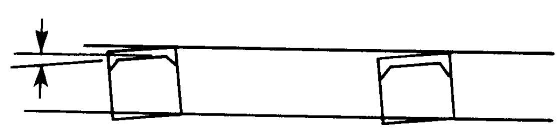

Figure 4
Lead Twist

1 Military Standards, Naval Publications and Form Center, 508 Tabor Ave., Philadelphia, PA 19120

(insert on received)

Figure 5
Stamped Leadframe Terminology

lead twist — Angular rotation on bonding fingers (see Figure 4).

pits — Shallow surface depressions or craters in the leadframe material.

slug marks — Random dents in the leadframe caused by foreign material in the stamping die.

stamped leadframe terminology — See Figure 5.

Z plane — Lead and pad planarity require a reference in the Z dimensions. The recommendation for the reference plane, hereafter called the "Z" plane, is the average of the two dambars when measured at their geometric center. This reference method is incorporated into SEMI G10.

4 Ordering Information

Purchase orders for leadframes for plastic molded dual-in-line semiconductor packages furnished to this specification shall include the following items:

1. Part Specification
2. Material
3. Number of Leads
4. Material Certification
5. Packaging and Marking (see Section 8)

5 Dimensions

See applicable part specification as referred to in Ordering Information, Section 4.

6 Defect Limits and Parameters(See SEMI G10 to Measure)

6.1 *Bond Targets*

6.1.1 Minimum area for bonding to allow placement of true position target of diameter taken (See Table below); 100% within the lead flat area and recommended to be 0.025" (0.63 mm) length from the tip, where plane geometry allows. (See SEMI G10, Section 14.)

Design Lead Width	*Design Lead Space*	*Minimum Lead Space*	*Minimum True Position Target*
≥ 0.011	≥ 0.011	0.006	0.007 Diameter
0.010	0.010	0.005	0.006 Diameter

NOTE: Tolerances for lead designs smaller than 0.010 should be negotiated between vendor and user.

6.1.2 Minimum metal to metal clearance to be as follows:

Material gage 0.010" (0.25 mm) – 0.006" (0.15 mm)

Material gage 0.008" (0.20 mm) – 0.004" (0.10 mm)

(See SEMI G10, Section 14)

6.1.3 Depth of coining on stamped leadframes to be no greater than 30% of material gage. (See SEMI G10, Section 15.)

6.1.4 Lead twist is not to exceed 3° 30' (0.0006" per 0.010" (0.016 mm per 0.25 mm)). (see SEMI G10, Section 3).

6.1.5 Lead tip will exhibit maximum 0.006" (0.15 mm) radius measured in the x-y plane at the lead flat surface (see Figure 6).

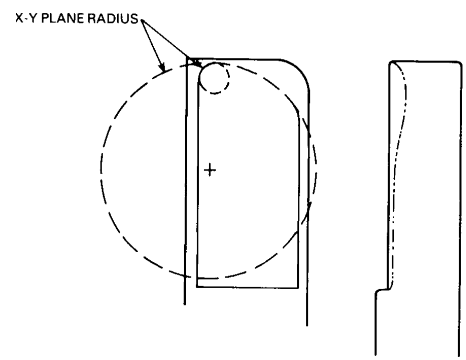

Figure 6
Lead Flat Radius

6.2 *Die Attach Pad Surface*

6.2.1 Die attach pad x-y axis location to be as follows:

rail-pad tie bar length	0.50" (12.5 mm) ± 0.002" (0.05 mm)
rail-pad tie bar length	0.50" (12.5 mm) ± 0.003" (0.08 mm)

from nominal drawing location. (See SEMI G10, Section 14.)

6.2.2 Die attach pad tilt to be as follows:

depressed pad — maximum 0.002" (0.05 mm) per 0.100" (2.5 mm)

undepressed pad — maximum 0.001" (0.025 mm) per 0.100" (2.5 mm) (see SEMI G10, Section 5)

6.2.3 Die attach pad flatness to be within 0.0002" (0.005 mm) T.I.R. per 0.100" (2.5 mm).

6.3 *Die Attach Pad Downset*

6.3.1 Die attach pad downset to be maximum ± 0.002" (0.05 mm) of nominal specified downset (see SEMI G10, Section 9).

6.4 *Lead and Die Attach Pad Planarity*

6.4.1 *Lead Planarity* — (See SEMI G10, Section 8)

6.4.1.1 Allowable tolerance is given by the following:

Strip Width	*Material Gage, 0.010" (0.25 mm)*	*Material Gage, 0.008" (0.20 mm)*
less than 1.000" (25.4 mm)	± 0.004" (0.10 mm)	± 0.003" (0.08 mm)
1.00" (25.4 mm) to 2.00" (50.8 mm)	± 0.005" (0.13 mm)	± 0.004" (0.10 mm)
greater than 2.00" (50.8 mm)	± 0.010" (0.25 mm)	± 0.008" (0.20 mm)

(See SEMI G10, Section 8.)

6.4.2 Die attach pad planarity (see SEMI G10, Section 11).

6.4.2.1 Allowable pad planarity tolerance, downset pad condition is given by the following:

Strip Width	*Tolerance*
Less than 0.75" (18.75 mm)	± 0.002" (0.05 mm)
0.75" (18.75 mm) to 1.00" (25.4 mm)	+0.003" (0.08 mm) to –0.005" (0.13 mm)
Greater than 1.00" (25.4 mm)	+0.006" (0.15 mm) to –0.003" (0.08 mm)

(See SEMI G10, Section 11.)

6.4.2.2 Allowable pad planarity tolerance, undepressed pad condition will not be specified in this document and is subject to vendor/customer negotiation.

6.5 *Material Tolerance*

6.5.1 Material dimensional tolerances are to be given by SEMI G4.

6.6 *Coil Set*

6.6.1 Coil set shall not exceed 0.020" over nominal length of the cut strip (see SEMI G10, Section 10).

6.7 *Crossbow*

6.7.1 Crossbow shall not exceed 0.5% of nominal strip width (see SEMI G10, Section 7).

6.8 *Camber*

6.8.1 Camber shall not exceed 0.002" (0.05 mm) over gage length of 6.00" (150 mm) (see SEMI G10, Section 6).

6.9 *Strip Pitch*

6.9.1 Strip pitch tolerance shall be ± 0.002" (0.05 mm) over the maximum measurable progression within the nominal strip length (see SEMI G10, Section 4).

6.10 *Burrs*

6.10.1 Burrs shall be firmly attached and able to withstand a probe force of 10 grams. Vertical burrs inside the dambar shall not exceed 0.001" (0.025 mm). Vertical burrs outside the dambar and horizontal burrs in any location shall not exceed 0.002" (0.051 mm) (see SEMI G10, Section 12).

6.11 *Pits (Indentations)*

6.11.1 Within function area and on external leads, there shall be no measurable slug marks. Pits shall not exceed 0.0003" (0.008 mm) in depth and 0.0005" (0.013 mm) in largest surface dimension in these areas (see SEMI G10, Section 13).

APPLICATION NOTE: There is a question regarding the ability of material suppliers to meet this specification. Revision of this specification is under review.

6.11.2 In other areas, pits and imperfections shall not affect leadframe strength regardless of size and shall not exceed 0.002" (0.051 mm) in depth and 0.005" (0.127 mm) in largest surface dimensions (see SEMI G10, Section 13).

6.12 *Plating*

6.12.1 All plating related characteristics shall be specified by SEMI G21.

6.13 *Strip Length and Cutoff* — (See SEMI G10, Section 14.)

6.13.1 Strip cutoff location shall be ± 0.003" (0.08 mm) of specified nominal location.

6.13.2 Overall strip length shall be ± 0.003" (0.08 mm) of specified nominal length.

6.14 *Lead Fatigue* — Number of cycles to be determined between customer and supplier. (See SEMI G10, Section 16.)

7 Sampling

Sampling will be determined between supplier and purchaser.

8 Packaging and Marking

8.1 *Packaging* — Leadframes must be packaged in containers designed and constructed to prevent damage and/or contamination. Specific protection must be provided against foreseeable mechanical and environmental hazards.

8.2 *Marking* — The outer containers shall be clearly marked identifying the user stock number, user purchase order number, drawing number, and vendor lot numbers within the carton.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI G10-96
STANDARD METHOD FOR MECHANICAL MEASUREMENT OF PLASTIC PACKAGE LEADFRAMES

1 Purpose

This method outlines standard mechanical measurement techniques for cut strip leadframes.

2 Scope

This method applies to all facilities that perform mechanical measurements on leadframes. Information is provided herein to enable the use of the following specifications: SEMI G9, SEMI G27, and SEMI G28.

3 Referenced Documents

None.

4 Terminology

None.

5 Equipment

1. Surface illuminated optical comparator with x-y grid
2. Toolmaker's microscope with depth ("z") reading capability, 100×, 400×, obtained with 10× objective, and 40× objective lens with 0.0002" resolution.
   a. Digital readout 0.0002" resolution on x-axis (optional)
   b. Closed circuit TV and camera (optional)
3. Surface plate
4. Gage pins
5. Universal leadframe fixture (see Figure 16)
   a. Fixture shall be perpendicular to optics within the resolution of the instrument and parallel to x and y travel axes.
   b. Leadframe strip shall be placed lead-flat surface up and clamped at rails to fixture base.
   c. The reference plane for measurement, hereinafter called the "z" plane, is the average of the height of the two dambars when measured at their geometric center.
   d. Z-plane cannot be established by this method if the dambar height measurement difference is greater than 0.003". Therefore, units that exhibit greater than 0.003" difference are not acceptable for z-axis measurement.
6. Leadframe camber fixture
   a. Nominal strip orientation defined in Figure 8.
7. Lead fatigue tester
8. Metal-to-metal clearance step gage (see Figure 13)
9. 0-1", 0.0001" reading micrometer
10. Overlay (see Figure 17)
    a. Overlay reference point shall be based on strip pilot holes. If pilot holes are off screen, x-y offsets of overlay pilot position to actual pilot position shall be specified.
    b. True position targets shall be placed on nominal lead center line 0.0065" (0.163 mm) back from nominal lead tip.
    c. Overlay will contain nominal pad location outline.
    d. Overlay will contain nominal strip cutoff position and required x-axis traverse for alignment.

6 Procedure for Lead Twist (Z-Axis) (See Figure 1)

Equipment — Toolmaker's microscope (400× magnification), leadframe fixture.

6.1 Fixture leadframe and establish z-plane as described in Section 5, items 5a and 5b.

6.2 Focus microscope on the edge of the coined surface 0.010" back from the end of the lead tip on the lead to be measured. Ensure that the focus is done on the flat-coined surface and not on the rolled edge. Zero the focal height (z-axis).

6.3 Using the micrometer drum, move the stage the specified distance and refocus the microscope. Ensure that both focus points are on the flat-coined surface, and not on the rolled edge. Focal height difference is the lead twist measurement.

7 Procedure for Strip Pitch (X-Axis) (See Figure 2)

Equipment — Optical comparator (20× lens), piece part drawing.

7.1 All measurements will be taken from the pilot holes referred to on the piece part print unless otherwise noted.

7.2 Line up the pilot holes at each end of the strip so that they are in the same horizontal plane. Center the pilot hole by rotating the comparator screen 45° (Figure 3). Ensure that the vertical and horizontal lines (now at 45°) are tangent to the edge of the pilot hole. Zero the readout, move the stage (horizontal travel) to the proper pilot hole at the end of the strip. Center the specified pilot hole on the strip. Read the horizontal readout for the strip pitch measurement.

8 Procedure for Pad Tilt (Z-Axis) (See Figure 4)

Equipment — Toolmaker's microscope (100× magnification), leadframe fixture.

8.1 Fixture leadframe and establish z-plane as described in Section 5, items 5a and 5b.

8.2 All targets are to be located .005" (.127 mm) in from cut edge, ensuring that the target is not located on the rolled edge.

8.3 Focus the toolmaker's microscope on one target crossbow (A), zero focal height (z-axis).

8.4 Use the barrel micrometer to move to the second target (B) of the die-attach pad. Note traverse distance for extrapolation of specification. Refocus the microscope. The focal height (z-axis) difference is the tentative pad tilt measurement.

8.5 Repeat at targets shown in Table 1.

Table 1 Measurement Targets

	A	B
2 Tie bars	1	2
	3	4
3 or more	1	2
Tie bars	3	4
	1	3
	2	4

8.6 Pad tilt is worst case of tentative measurements taken per Table 1.

9 Procedure for Camber (See Figure 5)

Equipment — Camber fixture

9.1 Place the part to be measured in the camber fixture on the comparator table. Ensure the strip rests against the gage pins.

9.2 Place the horizontal center line on the strip edge then down at the aperture.

9.3 This dimension, less gage distance, is the camber measurement. Traverse the stage to bring the horizontal center line to the reference edge.

10 Procedure for Crossbow (See Figure 6)

Equipment — Toolmaker's microscope (100× magnification), leadframe fixture.

10.1 Fixture leadframe and establish z-plane as described in Section 5, items 5a and 5b.

10.2 Focus the toolmaker's microscope on the center of top rail above the dambar (1). Zero focal height (z-axis).

10.3 Move to the center of the opposite rail above the dambar (2) and refocus. Average these two focal heights to establish the base zero focal height.

10.4 Move to the center of the dambar (3) and refocus. Focal height difference to base zero focal height is the crossbow measurement.

11 Procedure for Lead Planarity (See Figure 7)

Equipment — Toolmaker's microscope (100× magnification), leadframe fixture.

11.1 Fixture leadframe and establish z-plane as described in Section 5, items 5a and 5b.

11.2 Focus the toolmaker's microscope on the center of the dambar (1), then zero the focal height (z-axis).

11.3 Move to the center of the opposite dambar (2) and refocus. Average these two focal heights to establish the base zero focal height.

11.4 Move to subject lead (3) and refocus .010" (.254 mm) back from the lead tip. Note z-axis difference to base zero focal height. Subtract measured coin depth to give actual planarity measurement. Repeat above procedure for all leads to be measured. Be sure to record the plus (+) or minus (–) sign for each reading.

12 Procedure for Downset (See Figure 9)

12.1 Fixture leadframe and establish z-plane as described in Section 5, items 5a and 5b.

12.2 Focus the toolmaker's microscope at the location numbered in Column A of Table 2 and zero the focal height (z-axis). Move the workholder so that the corresponding location from Column B is under the microscope and refocus. The difference in readings is the downsetmeasurement.

Table 2

	A	*B*	*Destination*
P-dip	1	2	Bottom
	3	4	Top
Quad	1	2	1st Quad
	3	4	2nd Quad
	5	6	3rd Quad
	7	8	4th Quad

12.3 Repeat this for all tie bars indicated in Table 2.

12.4 All measurements must fall within the specification that applies.

13 Procedure for Coil Set (See Figure 10)

Equipment — Surface plate, gage pins

13.1 Place the strip on the surface plate, bond target side down, depressed pad up.

13.2 Slip gage pins under until you find the largest size that will fit under freely at possible locations shown. Pin diameter is the coil set measurement, noting the + or designation of coil set direction per Figure l0.

14 Procedure for Pad Planarity (Z-Axis) (See Figure 11)

Equipment — Toolmaker's microscope (100× magnification), leadframe fixture.

14.1 Fixture leadframe and establish z-plane as described in Section 5.5.

14.2 Move to the center of the die-attach pad (3) and refocus. The focal height difference is the pad planarity measurement.

15 Procedure for Burrs (X, Y, Z-Axis)

15.1 *Vertical Burrs* — (See Figure 12.)

Equipment — Toolmaker's microscope (400× magnification), leadframe fixture.

15.1.1 Fixture leadframe lead flat down and establish z-plane as described in Section 5, items 5a and 5b.

15.1.2 Focus the toolmaker's microscope on point A. Zero the focal height (z-axis).

15.1.3 Move to the top of the burr (Point B) and refocus the toolmaker's microscope. The focal height difference is the height of the vertical burr.

15.2 *Horizontal Burrs (X, Y-Axis)* — (See B, Figure 12.)

Equipment — Toolmaker's microscope (400× magnification).

15.2.1 Measure the horizontal burrs using the toolmaker's microscope in a similar manner to that described in 15.1.2 and 15.1.3.

15.2.2 Line up the cut edge (Point C) with the 0 center line on the toolmaker's microscope. Record the number on micrometer drum.

15.2.3 Move the stage to align the centerline with the end of the burr (Point D). The lateral movement (difference between start/end micrometer reading) will be the burr dimension.

16 Procedure for Pits, Slug Marks, Tool Marks (X, Y, Z-Axis), and Horizontal Burrs (See Figure 14)

16.1 *Depth (Z-Axis)*

Equipment — Toolmaker's microscope (400× magnification), leadframe fixture.

16.1.1 Fixture leadframe and establish z-plane as described in Section 5, items 5a and 5b.

16.1.2 Focus the toolmaker's microscope on the base of the material near the defect, then zero the focal height (z-axis).

16.1.3 Move to the pit, slug mark, or tool mark. Refocus on the deepest portion. The focal height difference (z-axis) is the depth of the pit, tool mark, or slug mark.

16.2 *Surface Dimension, Length, Width (X,Y-Axis)*

Equipment — Toolmaker's microscope (400× magnification), leadframe fixture.

16.2.1 Fixture leadframe and establish z-plane as described in Section 5, items 5a and 5b.

16.2.2 Line up to edge of the pit, slug mark, or tool mark on the cross hair. Note the micrometer drum reading.

16.2.3 Move to the opposite side of the pit, slug mark, or tool mark. The lateral movement (difference between start/end micrometer readings) is the pit, slug mark, or tool mark surface dimension.

17 Procedure for X-Y Dimensional Measurement

Equipment — Surface lit optical comparator, true position overlay, metal-to-metal step gage.

17.1 Align overlay to travel axes within the resolution of the instrument.

17.2 Position leadframe to overlay by optical methods.

17.3 Overlay targets will now be positioned to inspect lead-flat location.

17.4 Pad outline will be positioned to inspect pad location.

17.5 Metal-to-metal clearance is evaluated by use of step gage against leadframe image on comparator screen.

17.6 Traverse to specified distance to inspect cutoff position.

18 Method for Coin-Depth Measurement (See Figure 15)

18.1 Bend sample lead up for accessibility.

18.2 Measure material thickness beyond lead flat.

18.3 Measure material thickness within lead flat. Difference between two readings is depth of coining.

19 Procedure for Measuring Lead Fatigue

Equipment — Automatic or manual lead fatigue tester with 8 oz. ± .5 oz. weight.

19.1 Clamp leadframe strip on dambar of test frame (see Figure 18).

19.2 Clamp 8 oz. weight on bottom-half of lead (see Figure 19). Clamp must be at least L/2 from lead shoulder.

NOTE: If lead is clamped too close to shoulder, a reduction in measured lead strength will result, caused by twisting of weight.

19.3 Turn on lead fatigue machine and set all counters at zero.

19.4 Activate lead fatigue machine such that clamp arm rotates through 90° ± 5° (see Figures 20 and 21). This will result in actual bend of lead slightly less than 90°, depending on strength of metal.

19.5 Set machine to a two-to-five second cycle. One cycle defined to be a 90° rotation and back.

19.6 Count number of complete cycles until metal lead breaks and weight drops into pan.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI G11-88
RECOMMENDED PRACTICE FOR RAM FOLLOWER GEL TIME AND SPIRAL FLOW OF THERMAL SETTING MOLDING COMPOUNDS

1 Scope

This method describes a procedure for measuring the flow and gel characteristics of semiconductor grade transfer molding compounds using a ram follower device.

2 Applicable Documents[1]

ASTM D 3123 — Plastics, Molding, and Extrusions

3 Significance

3.1 The flow of a molding compound depends on the interaction of several variables, and is a measure of the combined characteristics of speed of gelation and melt viscosity of the particular compound under the specified conditions. The test is not a valid method for comparing the moldability of different compounds since a spiral flow test cannot duplicate actual molding conditions in different types of molds.

3.2 The moldability of thermosetting molding compounds has generally been defined by a single spiral flow number. The ram follower device follows graphically the molding compound as it melts and the rate of flow increases, as viscosity builds up due to resin polymerization, and as the flow of the compound ceases. Thus, it measures the gelation point of the compound, or the point where the material ceases to flow. This information can be an aid in characterizing the rheological behavior of the molding compound.

4 Apparatus

4.1 *Transfer Molding Press* — With a platen area sufficient to maintain a uniform mold temperature and having (1) a transfer piston pressure potential of 1000 psi on the material; (2) sufficient clamping pressure to prevent flashing of the molding compound; and (3) a minimum plunger speed of 25.4 mm (1 inch) per second without load. The pot diameter shall be 31.75 to 44.45 ± 0.635 mm (1.250 to 1.750 ± 0.025 inch) and the clearance between pot and ram shall be sufficiently small that flashing does not occur above the first sealing groove on the ram.

4.2 *Standard Spiral Flow Mold* — Per ASTM D 3123.

4.3 *Ram Following Apparatus* — Consisting of a displacement transducer attached to the transfer ram of the press in such a way as to accurately record its movement, suitable power supply for the displacement transducer, and a recorder capable of recording the signal from the displacement transducer and preferably having a chart speed of at least 10 mm per second. An optional velocity transducer can also be used as a means of directly measuring ram velocity and verifying the starting and ending of the flow process. In this case, a 2-channel recorder is needed.

4.4 *Thermocouple and Potentiometer* — Calibrated in the 149° to 177°C (300° to 350°F) range. (Calibration to be checked every six months.)

5 Test Conditions

5.1 *Molding Compound* — Refrigerated shipment and storage of some molding compounds is necessary. The molding compound is to be at room temperature before the container is opened. Once the compound has equilibrated to room temperature, the test should be run within 16 hours. Care must be taken to preserve the original moisture content. The material should be in powdered form, unless otherwise specified.

NOTE: Room temperature defined to be 23° ± 5°C.

NOTE: Refer to manufacturers' recommendations regarding shelf life differences which may exist between molding compounds.

5.2 *The Spiral Flow Mold* — Shall be clean and free from any mold release agents or lubricants. A standard mold cleaning compound can be used to insure mold cleanliness.

5.3 *Molding Conditions*

5.3.1 The temperature of the mold shall be measured using a thermocouple inserted in the mold. The ram shall be kept at the mold temperature. Molding temperature is to be as recommended by the material specification unless otherwise specified. Temperature must be maintained within ± 3°C (± 5°F) of the specified temperature.

NOTE: Flow duration is strongly influenced by temperature. For critical determinations, the temperature should be maintained as close to the nominal temperature as practical, preferably within ± 0.5°C (± 1°F).

5.3.2 The weight of the charge shall be adjusted to give a molded cull thickness of 3.302 ± 0.254 mm (0.130 ± 0.010 in.), excluding vertical flash.

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohoken, PA 19428-2959

5.3.3 The free running ram speed shall be at least 25.4 mm/sec (1"/sec). Recommended speed is 100 ± 25 mm/sec into the pot and application of pressure on the charge shall not exceed 5 seconds.

5.3.4 The transfer pressure measured under the transfer plunger is to be 6.895 ± 0.177 mpa (1000 ± 25 psi) unless otherwise specified.

5.3.5 Unless otherwise specified, a minimum of 1.5 minutes close and cure time shall be used.

5.4 *Flow Length* — Read the spiral flow length directly from the molded specimen at the point of farthest continuous flow to the nearest 6.35 mm (0.25 in).

5.5 *Flow Duration* — The flow duration or gel time is defined as the time interval between the moment when the ram contacts the charge and the time the ram stops moving. The contact and gelation points are determined from the ram follower trace.

6 Procedure for Spiral Flow

6.1 Thoroughly clean the ram, pot, and mold of any cured compound, or other foreign matter.

6.2 Heat the mold and ram to within (± 3°C) of the specified temperature.

6.3 At the beginning of each series of tests and at each change of compound, check and set the transfer pressure using the force gage. The proper force gage setting can be determined from the formula:

$$F = \frac{\pi D^2 P}{4}$$

where F is the force in pounds, P is the desired pressure on the material in psi and D is the ram diameter in inches.

6.4 For each material change, make at least three “clean out” runs using the material to be tested before recording data. These runs may be used to determine the charge weight.

6.5 Weigh out the compound to the nearest 0.1 g as previously determined to yield a cull of 3.302 ± 0.254 mm (0.130 ± 0.010 in.).

6.6 Raise the ram, add the compound to the pot, and immediately activate the transfer cycle. If the recorder does not have a remote on-off that is activated by the cycle start, then it should be started before the cycle starts. After the ram motion ceases, the chart may be stopped.

6.7 Open mold and remove cured material. Measure cull thickness. If the cull is not within 3.302 ± 0.254 mm (0.130 ± 0.010 in.), discard run and repeat the test, adjusting the charge weight as necessary.

6.8 Read the flow length to the nearest 6.35 mm (0.5 in.).

6.9 Mark the point on the chart where the ram contacts the charge. This point is identified on the displacement trace as the point at which the rate of displacement initially changes.

6.10 Mark where the ram stopped moving. Caution should be exercised where significant flashing occurs. Count the number of divisions between the two points and divide by the chart speed. The result is the flow duration or gel time in seconds. Record this time to the nearest second.

6.11 If the optional velocity trace is available, mark point on the chart where the ram contacts the charge. This point is identified on the velocity trace as the point at which the transfer velocity transducer initially detects a significant reduction in velocity output.

6.12 Mark where the ram stopped moving. In order to detect the point of zero (0) velocity, the signal must be of sufficient magnitude. Count the number of divisions between the two points and divide by the chart speed. The result is the flow duration or gel time in seconds. Record this time to the nearest second.

6.13 If both displacement and velocity transducers are used, the starting and ending points should agree, therefore yielding the same gel time.

6.14 Repeat step 6.5 at least 3 times for repeatability.

7 Reporting of Results

7.1 Report the material designation and lot number.

7.2 Report the average and standard deviation of the flow length and gel time.

7.3 Report the temperature and pressure used for the tests.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI G13-88
STANDARD TEST METHOD FOR EXPANSION CHARACTERISTICS OF MOLDING COMPOUNDS

1 Scope

1.1 This specification describes the procedure for measuring the Coefficient of Thermal Expansion (CTE) and Glass Transition Temperature (T_g) of thermosetting molding compounds.

2 Apparatus

2.1 *Mold* — Producing 0.1–0.2" cubes or equivalent with an aspect ratio of 0.8–1.

2.2 *Transfer Press*

2.3 *Micrometer* — (0.0001 accuracy)

2.4 *Thermomechanical Analyzer* — (TMA) (Dupont Model 943, Perkin-Elmer TMS-1, or equivalent)

2.5 *Recorder and Power Supply* — (Dupont Model 990, Perkin-Elmer UUI, or equivalent)

2.6 *Oven* — (200° ± 5°C capability)

3 Materials

3.1 *Nitrogen (Gas)*

3.2 *Nitrogen (Liquid)*

4 Sampling

4.1 Mold samples according to product specifications.

4.2 Postcure the specimen in accordance with the material specification, and allow two (2) hours for cooling in a desiccator.

5 Procedure

5.1 Select a sample, making certain that all sides are flat and smooth. Measure the height of the sample with a micrometer to the nearest 0.0001 inch.

5.2 Place the sample into the TMA sample holder and bring the expansion probe down slowly until it just makes contact with the sample. Place sample on fixture per Instruction Manual. Add 3.0–5.0 grams to weight tray. Adjust the Linear Variable Differential Transformer (LVDT) to bring the recorder pen on scale. The LVDT is then zeroed with the zero switch. Readjust LVDT, if necessary, to bring pen on scale.

5.3 In a nitrogen atmosphere, heat the sample at a rate of 20°C/min. to its post-cure temperature.

5.4 Without changing LVDT or probe position, use liquid nitrogen to cool the sample to a temperature at least 100°C below the deviation from α_1.1.

5.5 Heat the sample at a rate of 5°C/min. to at least 200°C.

5.6 Calculate α(CTE), using the formula:

$$CTE = \left[\frac{(DL)(DY)}{(DT)(L)} \right]$$

where: $L_{(T+10°)}$=Length at Temperature 10° higher than temperature at which CTE is being measured. $L_{(T-10°)}$=Length at Temperature 10° lower than temperature at which CTE is being measured

ΔY = Y axis sensitivity in mils./in.

ΔT = change in temperature (20°C)

L = initial sample height (mils)

$$K = \frac{\text{LIT CTE}}{\text{EXP.CTE}} \text{ for aluminum standard}$$

5.7 Run two (2) samples for each lot and record the average.

5.8 An aluminum standard should be run to determine the calibration factor K for the Y (length) axis per 5.4 above, as necessary to insure the accuracy of the instrument's calibration.

5.9 Temperature readings should be calibrated periodically per manual instructions.

6 Report

6.1 Data is to include the orientation for which the sample is measured (e.g., perpendicular to flow).

6.2 CTE is reported as a function of temperature. CTE is to be reported every 10°C increments.

6.3 Report molding conditions and post-mold cure conditions.

6.4 Report specimen size.

NOTE: For many materials, the Glass Transition Temperature (Tg) may be determined by drawing tangents to the curve at the points of minimum and maximum slope. The point at which the tangents intersect is the T_g. The slopes of the lines are referred to as α 1 (below T_g) and α2 (above T_g).

SEMI G14-88
GUIDELINE FOR SPECIFYING THE DIMENSIONS AND TOLERANCES USED TO MANUFACTURE PLASTIC MOLDED DIP PACKAGE TOOLING

1 Preface

1.1 This document is a guideline for the ordering of tooling required to mold and form plastic molded DIP semiconductor packages. It is to be used by packaging engineers, mold manufacturers, and end-of-line tool makers as the basis for defining the limits of manufacturing tolerances.

2 Applicable Documents

2.1 This document specifically refers to:

JEDEC Publication No. 95[1] — JEDEC Registered and Standard Outline for Semiconductor Devices

2.2 Related information may also be found in:

MIL-STD-100[2] — General Engineering Drawing Practices

ANSI Y14.5[3] — Dimensioning and Tolerancing

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

3 Selected Definitions — Product Criteria Tolerance Limits

3.1 *mismatch and offset* — Defined with respect to package only. All statements will be equally applicable in two (2) axes. All mismatch and offset measurements are made after molding and prior to trimming.

3.1.1 *cavity to frame offset* — Will be measured prior to any trimming operation. Offset will be defined as the difference in bottom cavity position with respect to a leadframe datum. The offset measurement will exclude leadframe tolerances. (See Figure 1.)

3.1.2 *top to bottom cavity mismatch* — Characterized by the fact that the top and bottom cavities in the mold are not aligned properly, causing a mismatch condition. The measurement shall be stated as the difference in the top cavity position relative to the bottom cavity position. (See Figure 2.)

3.2 *parting line protrusions* — Those plastic excesses which remain as a normal characteristic after normal trimming and molding operations. (See Figure 4.)

3.3 *top or bottom protrusions* — Those plastic excesses (includes ejector pin “crowns”) which remain as normal characteristics extending from the smooth surface of the molded package.

3.4 *variations in lead position* — Defined with respect to a 90° angle from the top or bottom of the smooth surface of the molded package as viewed on the end or side projections. (See Figure 4.)

3.5 *shoulder width intrusions/protrusions* — Any variations in straightness along the defined shoulder width caused by dambar removal. (See Figure 4.)

3.6 *package warpage* — Any non-linear dimensional change from the mold cavity characteristic, usually caused by incorrect package design or molding practices. (See Figure 5.)

3.7 *shoulder bend location* — Measured from the outermost point of the inner shoulder bend radius. (See Figure 6.)

4 Ordering Information

Purchase orders for tooling for plastic molded DIP semiconductor packages furnished to this specification shall include the following items:

1. A package tooling outline drawing showing all required dimensions listed in 5. Package surface finish to be included.
2. A list of any tolerance limits which differ from the SEMI standards detailed in 6.
3. The type of tooling steel required.
4. The type of leadframe material to be used, including a drawing.
5. The type of plastic to be molded (if proprietary, a statement of its shrinkage characteristics).
6. Sampling plan for compliance to 7.
7. The number of spare parts or expendable parts desired.
8. Type of molding press to be used, including power requirements.

1 JEDEC, 20001 Eye Street N.W., Washington, D.C. 20006

2 Military Standards, Naval Publications and Form Center, 5801 Tabor Ave., Philadelphia, PA 19120

3 ANSI, 1430 Broadway, New York, NY 10018

9. Applicable leadframe drawing, showing all dimensions.

5 Dimensions

Drawing must show dimensions for the following items, if applicable:

1. Package length
2. Package width
3. Top cavity thickness
4. Bottom cavity thickness
5. Frame thickness
6. Top ejector pin locations from notch end
7. Bottom ejector pin locations from notch end
8. Ejector size (top and bottom)
9. Ejector depth (top and bottom), draft angle top side (bottom, side, and end)
10. End notch shape, depth, width, length
11. Pin 1 ID location from package center
12. Pin 1 ID shape and size
13. Corner radius on sides
14. Corner radius on ends
15. Lead spread (nominal) (see Figure 3)
16. Shoulder bend location
17. Shoulder width

6 Product Criteria Dimensional Tolerance Limits for DIPS

In recognition that every manufacturing process is subject to variation, the following list details the acceptable limits of this variation.

8 - 64 LEAD

(unless otherwise noted)

MISMATCH (see Figure 2)

	± 0.002"

PACKAGE/FRAME OFFSET (see Figure 1) (excludes leadframe tolerances)

8-64	± .002"

PROTRUSIONS (see Figure 4)

Parting line Side and End	0.006"(For reference use only)
Top Protrusion	0.001"
Bottom Protrusion	0.001"

INTRUSIONS (Ejector Pins)

	0.010" maximum

VARIATIONS IN LEAD POSITION (see Figure 4)

	0.007" True position non-accumulative

SHOULDER WIDTH PROTRUSIONS/INTRUSIONS (see Figure 4)

	+ 0.003"/- 0.002"

PACKAGE WARPAGE (see Figure 5)

Warp factor	2.5

SHOULDER BEND LOCATION (see Figure 6)

	JEDEC Publication No. 95 outline minus lead thickness. (Based on balanced plastic.)

LENGTH AND THICKNESS

	± 0.002" (see Figure 5) (Excluding protrusions)

7 Sampling

7.1 Samples used to determine compliance to Section 6 shall be determined between vendor and supplier.

8 Packaging

8.1 Tooling must be packaged in containers designed and constructed to prevent damage and/or contamination. Specific protection must be provided if tooling is to be shipped any great distance.

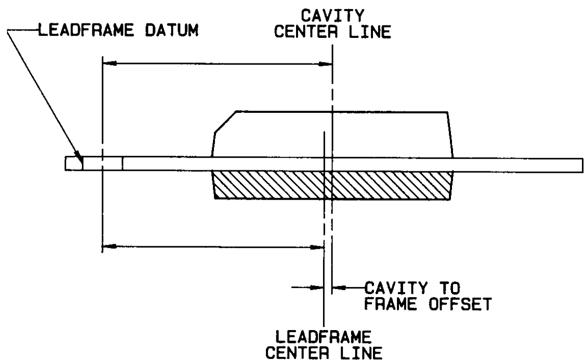

Figure 1

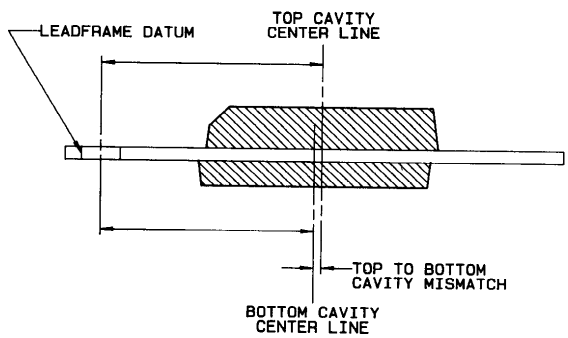

Figure 2

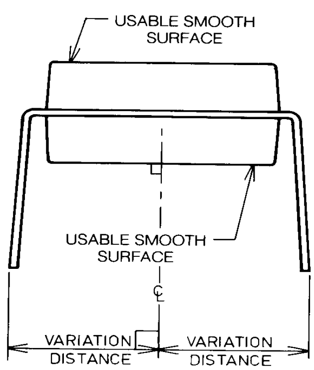

Figure 3
Variations from Nominal Lead Location

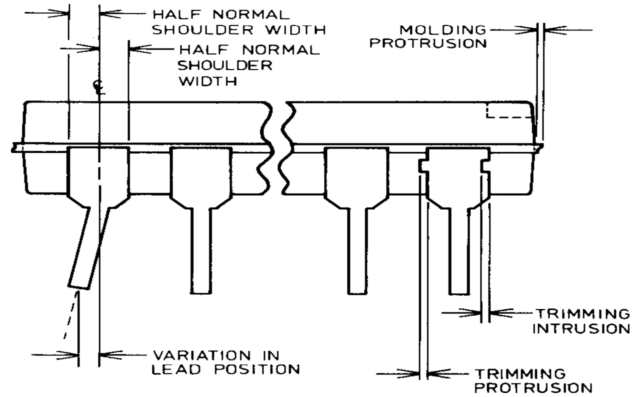

Figure 4
Parting Line Protrusions and Variation in Lead Position

SEMI G15-93
STANDARD TEST METHOD FOR DIFFERENTIAL SCANNING CALORIMETRY OF MOLDING COMPOUNDS

1 Preface

1.1 *Scope* — This document describes procedures for evaluating epoxy molding compounds by differential scanning calorimetry (DSC).

1.2 *Units* — This test method uses SI units.

2 Applicable Documents

2.1 *Reference Documents*

2.1.1 *ASTM Specifications*[1]

ASTM E 793 — Test Method for Heats of Fusion and Crystallization by Differential Scanning Calorimetry

ASTM E 967 — Practice for Temperature Calibration of Differential Scanning Calorimeters and Differential Thermal Analyzers

ASTM E 968 — Practice for Heat Flow Calibration of Differential Scanning Calorimeters

2.2 *Related Documents*

2.2.1 *ASTM Specifications*

ASTM E 473 — Standard Definitions of Terms Relating to Thermal Analyses

ASTM E 1269 — Test Method for Determining Specific Heat by Differential Scanning Calorimetry

3 Significance

3.1 DSC provides a rapid method at incoming inspection for evaluating molding compounds for consistency in subsequent molding processes.

4 Interferences

4.1 Very small quantities of material are used in the test. Lack of homogeneity may cause variable results.

4.2 *Gas Purge* — See Section 5.

4.3 *Sample Pans* — See Section 5.

5 Equipment

5.1 *Differential Scanning Calorimeter* — Capable of heating a sample from room temperature to 300°C with a controlled heating rate.

NOTE 1: Gas Purge Considerations — A reactive gas purge affects the material under test. A gas must be chosen that reflects the molding conditions normally used for that material (i.e., air or nitrogen).

5.2 *Sampling Pans for DSC Cell* — (Aluminum with crimping or hermetically sealed.) The pans must not be reactive to the sample under test.

5.3 *Process Controller* — Capable of collecting, calculating, and plotting the data resulting from the calorimeter.

5.4 *Analytical Balance* — Accuracy 0.001 mg.

5.5 *Tweezers and Microspatula*

6 Sampling

6.1 When the method is used to evaluate incoming molding materials, the sampling plan shall be agreed between supplier and customer.

6.2 Powdered or granular molding compounds shall be thoroughly mixed before sampling. If the compound is supplied in a preform, a small section may be cut off the preform with a blade.

7 Preparation of Samples

7.1 Protect samples from moisture absorption while awaiting test.

8 Equipment Setup and Calibration

8.1 *Temperature Calibration* — (Refer to ASTM E 967.)

8.1.1 Follow the manufacturer's operating manual to set up and run a calibration curve using indium (Melting Point 156.6°C) (see Figure 1).

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, PA 19428-2959

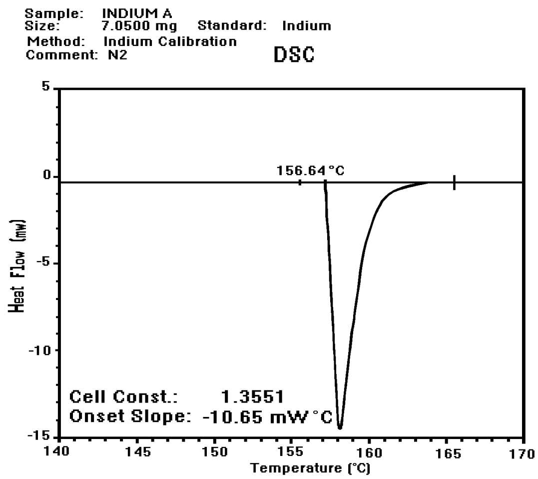

Figure 1

8.2 Determine the onset of melting and refer to the manual for the temperature correction method.

NOTE 2: There are other standard reference materials with higher melting points (see Table 1). Choose the standard which best matches the range of interest for the material under test.

Table 1

Reference Material	*Melting Point (°C)*
Indium	156.6
Tin	232.0
Zinc	419.6

8.2.1 Indium is also used to calibrate the Heat of Fusion for the DSC cell. Table 2 also lists the Standard Heat of Fusion for alternate materials that may be used.

Table 2

Reference Material	*Heat of Fusion (J/g)*
Mercury	11.44
Indium	28.42
Lead	23.16
Tin	59.23
Zinc	112.0

8.2.2 An area calculation of the indium melt provides the Heat of Fusion for DSC cell (see Figure 1).

8.2.3 Refer to the operating manual to obtain the cell constant and its correction.

9 Procedure

9.1 *Sample Size* — 2.000 to 12.000 mg may be used. 8.000 mg is commonly used. A small design of experiments exercise may be used to obtain the optimum sample size for the molding compound under test. Different compound chemistries may have an effect on the results if the sample size is not carefully chosen.

Place the sample in the sample pan.

9.2 Use an empty sample pan with its cover as a reference.

9.3 Carefully place the sample and reference pans onto their respective thermal sensors in the DSC cell. Seal the cell according to the manufacturer's instructions.

9.4 Set the heating rate to the optimum conditions determined for that instrument and the specific material under test. This rate will normally be between 5°C and 25°C per minute.

9.5 Activate the test sequence, and heat the sample from room-temperature to 300°C in order to obtain the DSC curve.

9.6 At the end of the run, remove the sample, and allow the DSC cell to cool to room-temperature in preparation for the next sample.

10 Results Report

10.1 The results report shall contain the following items:

10.1.1 Sample and equipment details

Molding material name/number

Sample weight

Equipment used

Heating rate

Calibration constant

Any pertinent information regarding material or equipment

10.1.2 *Scan Results* — The DSC curve shall indicate the following:

Maximum peak exotherm — units °C

Exotherm onset — units °C

Exotherm — units joules/gram

NOTE 3: The total exotherm is determined by an area calculation of the exotherm profile using a computer drawn baseline.

11 Accuracy and Precision (see ASTM E 968)

11.1 *Repeatability — Single Analyst* — The percent RSD over multiple days was determined to be 4.2%.

11.2 *Reproducibility — Multilaboratory* — The percent RSD was determined to be 8.2%.

12 Alternate Procedures

12.1 *Thermal Kinetic Modeling*

12.2 *Isothermal Differential Scanning Calorimetry* — There is a current lack of interlaboratory correlation to recommend this method.

NOTE 4: Manufacturers' literature may be used to obtain information on these methods.

SEMI G16-88
SPECIFICATION FOR DIMENSIONS AND TOLERANCES USED TO MANUFACTURE PLASTIC CHIP CARRIER TOOLING

1 Preface

This document is a guideline for the ordering of tooling required to mold and form plastic chip carriers. It is to be used by packaging engineers, mold manufacturers and end of line tool makers as the basis for defining the limits of manufacturing tolerances.

2 Applicable Documents

Related information may be found in:

MIL-STD-100[1] — Engineering Drawing Practices

ANSI Y14.5[2] — Dimensioning and Tolerancing

JEDEC Publication No. 95 [3] — Outline for Semiconductor Devices

3 Selected Definitions — Production Criteria Tolerance Limits

3.1 *mismatch and offset* — Defined with respect to package only. All statements will be equally applicable in two (2) axes. All mismatch and offset measurements are made after molding and prior to trimming.

3.1.1 *cavity to frame offset* — Will be measured prior to any trimming operation. Offset will be defined as the difference in bottom cavity position with respect to a leadframe datum. The offset measurement will exclude leadframe tolerances. (See Figure 1.)

3.1.2 *top to bottom cavity mismatch* — Characterized by the fact that the top and bottom cavities in the mold are not aligned properly, causing a mismatch condition. The measurement shall be stated as the difference in the top cavity position relative to the bottom cavity position. (See Figure 2.)

3.2 *Molded Protrusions*

3.2.1 *parting line protrusions* — Those plastic excesses which remain as a normal characteristic after normal molding, deflashing, trimming, and singulation. (See Figure 6.)

3.2.2 *top or bottom protrusions* — Those plastic excesses (includes ejector pin "crowns"), which remain as a normal characteristic extending from the smooth surface of the molded package.

3.3 *variations in lead location* — Defined with respect to a 90° angle from the top or bottom of the smooth surface of the molded package as viewed on the end or side projections. (See Figure 6.)

3.4 *lead shoulder protrusions and intrusions* — Any variations in straightness along the defined shoulder width caused by dambar removal. (See Figure 6.)

3.5 *package warpage* — Any non-linear dimensional change from the mold cavity characteristic, usually caused by incorrect package design or molding practices. (See Figure 3.)

3.6 *shoulder bend location* — Measured from the outermost point of the shoulder bend radius. (See Figure 4.)

3.7 *lead co-planarity* — Defined as the vertical lead position with respect to a reference plane measured after forming. (See Figure 5.)

4 Ordering Information

4.1 Purchase orders for tooling for plastic molded quad semiconductor packages furnished to this specification shall include the following items:

1. A package tooling outline drawing showing all required dimensions listed in Section 5. Package surface finish should be included.
2. A list of any tolerance limits which will differ from those detailed in Section 6.
3. The type of tooling steel required.
4. The type of leadframe material to be used.
5. The type of plastic to be molded (if proprietary, a statement of its shrinkage characteristics).
6. Sampling plan for compliance to Section 7.
7. The number of spare parts or expendable parts desired.
8. The type of molding press to be used, including power requirements.
9. Applicable leadframe drawing, including all dimensions.

1 Military Standards, Naval Publications and Form Center, 5801 Tabor Avenue, Philadelphia, PA 19120

2 ANSI, 1430 Broadway, New York, NY 10018

3 JEDEC, 2001 Eye Street, N.W., Washington, D.C. 20006

5 Dimensions

5.1 Drawing must show dimensions for the following items, if applicable:

1. Package length
2. Package width
3. Top cavity thickness
4. Bottom cavity thickness
5. Frame thickness
6. Ejector top locations from cavity center line
7. Ejector bottom locations from cavity center line
8. Ejector size (top and bottom)
9. Ejector depth (top and bottom, draft angle top side, bottom side, and end)
10. End notch shape, depth, width, length
11. Pin 1 ID location from package center
12. Pin 1 ID shape and size
13. Corner radius or sides
14. Corner radius or ends
15. Lead spread (nominal)
16. Shoulder bend location
17. Shoulder width

6 Product Criteria Dimensional Tolerance Limits for PCCs

6.1 In recognizing that every manufacturing process is subject to variation, the following list details the acceptable limit of this variation:

CAVITY MISMATCH	0.004" (0.101 mm)

PACKAGE/FRAME OFFSET	0.002" (0.05 mm) (excluding leadframe tolerances)

MOLDED PROTRUSIONS

(see Figure 6)	
Parting line	0.006" (0.15 mm)
Top or bottom	0.001" (0.025 mm)

VARIATION IN LEAD POSITION

(see Figure 6)	0.004" (0.101 mm)

SHOULDER INTRUSIONS AND PROTRUSIONS

(see Figure 6) Intrusions	0.002" (0.05 mm)
Protrusions	0.003" (0.08 mm)

PACKAGE WARPAGE

Warp factor	2.5

LEAD CO-PLANARITY	0.003" (maximum)

EJECTOR PIN DEPTH	0.010" (maximum)

7 Sampling

7.1 Samples used to determine compliance to Section 6 shall be determined between vendor and supplier.

8 Packaging

8.1 Tooling must be packed in containers designed and constructed to prevent damage and/or contamination. Specific protection must be provided if tooling is to be shipped any great distance.

SEMI G18-96
STANDARD FOR INTEGRATED CIRCUIT LEADFRAME MATERIAL USED IN THE PRODUCTION OF ETCHED LEADFRAMES

1 Purpose

This specification is for the leadframe material that will be shipped to an etch house. It is a leadframe specification, but deals with material aspects only.

2 Scope

This specification covers the special requirements for metal strip to be used to fabricate integrated circuit leadframes by etching.

3 Referenced Documents

3.1 *ASTM Specifications*[1]

ASTM B 601 — Recommended Practice for Temper Designations for Copper and Copper Alloys — Wrought and Cast

ASTM E 8 — Methods of Tension Testing of Metallic Materials

ASTM B 193 — Test Method for Resistivity of Electrical Conductor Materials

ASTM B 754 — Standard Test Method for Measuring and Recording the Deviations from Flatness in Copper and Copper Alloy Strip

4 Terminology

None.

5 Ordering Information

5.1 Orders for material under this specification shall include the following information:

1. Quantity of each size
2. Alloy name and number
3. Temper or mechanical properties
4. Dimensions: Thickness and width (see Section 7.3.)
5. How furnished: Coils and coil size or sheet size (see Section 10.)
6. Certification or test report requirements (see Section 11.)
7. Packaging and marking requirements (see Section 12.)

6 General Requirements

6.1 The materials covered by this specification shall conform to the requirements detailed in this specification, unless otherwise agreed upon by supplier and purchaser.

7 Dimension and Tolerances

7.1 The following tests shall be used to determine conformance or non-conformance to this specification.

7.2 *Etched Raw Materials Purchased in Coils* — Samples can be taken from the ID or OD of each coil. If the material does not conform to this specification, remove two wraps from the ID and OD of each coil and test for conformance again. Samples may also be taken from cut sheets.

7.3 *Thickness, Width, and Length* — The tolerances for thickness and width shall be as shown in Table 1. More restrictive tolerances than those shown in Table 1 or tolerances for other thicknesses and widths shall be agreed upon between user and supplier.

Table 1 Thickness and Width Tolerances

Thickness	*Tolerance*
0.005 - 0.010" (0.127 – 0.254 mm)	± 0.0003" (0.008 mm)
0.015" (0.381 mm)	± 0.0004" (0.010 mm)
0.020" (0.508 mm)	± 0.0005" (0.013 mm)
Width	*Tolerance*
2.000 - 8.000" (25.4 - 203.2 mm)	± 0.005" (0.127 mm)
> 8.000" (> 203.2 mm)	to ± 0.010" (0.254 mm)

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohoken, PA 19428-2959

7.4 *Camber (Edgewise Curvature)* — Camber is not critical for material used in the etching process provided the end product (leadframe strip) meets its requirements; ± 0.0625" (1.6 mm) in 36" (91 cm) is considered acceptable.

7.5 *Coil Set* — A three foot long sample shall be obtained from each coil supplied. The measured coil set shall not exceed 1.500" (38.1 mm).

7.6 *Edge Burrs* — Undesirable and, if present, their height shall not exceed 10% of the metal thickness.

7.7 *Crossbow (Dish)* — Crossbow is a function of slitting. Because material for the photo chemical process is generally about 16–20" wide, crossbow is not a critical problem. However, the final product (leadframe strips) must meet maximums, as suggested in Table 2, and crossbow in the sheet form, shall not be present to the extent that this specification cannot be met.

Table 2 Maximum Crossbow

Specified Strip Width	*Maximum Crossbow*
Up to 1.000" (25.4 mm), incl.	0.003" (0.076 mm)
Over 1.000" (25.4 mm)	0.005" (0.127 mm)

7.8 *Oil Can* — When any part of a sheet is pushed, but not bent, and it snaps into a different position or plane other than the original position with no further pressure, oil canning is present. Oil canning shall not be present on materials being used in the photo chemical process (etching) to the extent that the maximum crossbow specification on the finished product (see Table 2) cannot be met.

8 Surface Finish

8.1 The material shall be commercially free of surface imperfections such as pits, nicks, dents, gouges, scratches, laminations, or inclusions.

8.2 Surface defects less than 0.0003" (0.0076 mm) in depth will be acceptable unless otherwise agreed upon between the supplier and purchaser.

APPLICATION NOTE: There is a question regarding the ability of material suppliers to meet this specification. Revision of this specification is under review.

9 Corrosion

9.1 Visual inspection shall be used to determine if objectionable surface oxides are present which would render the product unusable for the intended application. Objectionable conditions, if present, should be reported to the supplier within 60 days after receipt of the material.

9.2 There shall be no visible rust on the surface of Alloy 42 material.

10 Coils

10.1 Unless otherwise specified, coils shall be supplied with an inside diameter that provides for good packing practice without resulting in excessive coil set.

11 Certifications or Test Reports

11.1 Requests for certifications or test reports shall be made at the time of order entry or contract agreement. They shall be furnished by the manufacturer within one week of date of shipment.

11.2 When certifications are required, the following information shall be supplied as a minimum:

1. Vendor name
2. Purchase order number
3. Vendor order number
4. Alloy name and number
5. Chemical analysis
6. Temper designation (reference only)
7. Tensile strength
8. Elongation percent in 2"
9. Electrical conductivity % IACS (for copper base alloys only)

11.3 In the event of a disagreement between supplier and purchaser, an independent test shall be conducted on the strip to verify the data provided in the certification.

12 Packaging and Marking

12.1 The material shall be separated by size, composition, and temper, and prepared for shipment in such a manner as to ensure acceptance by a common carrier for transportation at the lowest applicable rate.

12.2 The material shall be suitably packaged to protect from condensation, contamination, etc., and to afford protection from the normal hazards of transportation.

12.3 Each shipping unit shall be legibly marked with the purchase order number, alloy name or number, temper, size, gross and net weight, and name of the supplier. The specification number shall be shown when specified on the purchase order.

12.4 Any special packaging or shipping requirements shall be agreed upon between supplier and purchaser at the time of purchase.

13 Basis for Rejection

13.1 For the purposes of determining conformance with the requirements prescribed in the specification, any measured value outside the specified limiting values shall be cause for rejection.

13.2 If objectionable material is found and rejected, samples of the questionable material, with the defects identified and marked, should be sent to the supplier along with information as to order number, quantity originally received, date received, and quantity rejected. Rejected material should be held with adequate protection and identification by the purchaser for a reasonable amount of time, pending investigation by the supplier.

SEMI G19-0997
SPECIFICATION FOR DIP LEADFRAMES PRODUCED BY ETCHING

1 Preface

This specification is a guideline for production of DIP leadframes for plastic molded semiconductor packages produced by the etching process. It is a design guideline for packaging engineers, etchers, and mold manufacturers and has been developed to meet the requirements of automatic bonders.

2 Applicable Documents

2.1 *SEMI Standards*

SEMI G18 — Specification for Integrated Circuit Leadframe Material Used in the Production of Etched Leadframes

SEMI G10 — Standard Method for Mechanical Measurement of Plastic Package Leadframes

2.2 *Other Document*

PCM1 D-300[1] — Standard Specification

3 Selected Definitions

burrs and protrusions — Fragments of excess material, either horizontal or vertical, attached to the lead frame.

camber — Curvature of the leadframe strip edge (see Figure 1).

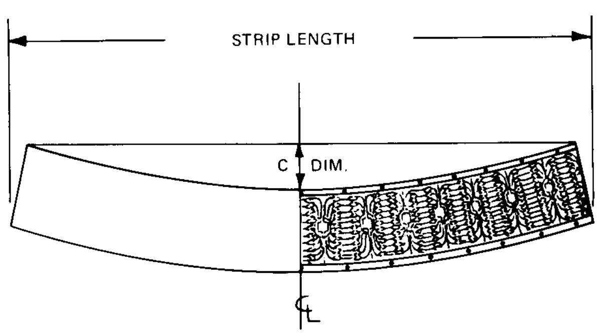

Figure 1
Camber

coil set — Longitudinal bowing of the leadframe (see Figure 2).

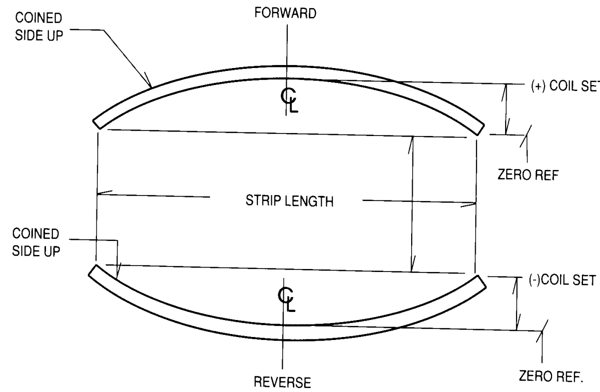

Figure 2
Coil Set

compensation — Changes made in the dimensions on the master artwork other than those specified on the engineering artwork that allow for the process variables (i.e., etch factor, undercut).

crossbow — Transverse bowing of the leadframe (see Figure 3).

(enter graphic when available)

Figure 3
Crossbow

etch factor — The ratio of etched depth to the lateral etch or undercut (see Figure 4).

1 Photochemical Machining Institute, 4113 Barberry, Lafayette Hills, PA 19444

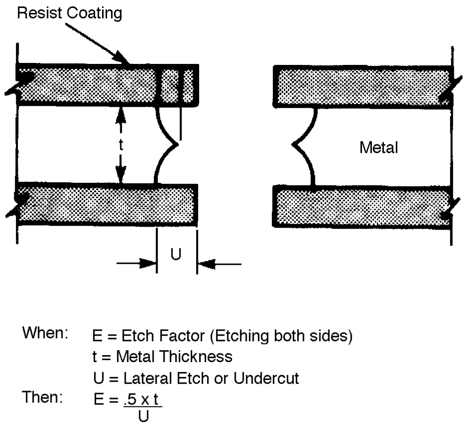

Figure 4
Undercut and Etch Factor

functional area — The die attach pad and wire bond (lead tip) area.

lateral etch or undercut — The allowable bevelled edge caused by the leadframe etchant attacking the metal laterally as well as vertically (see Figure 5).

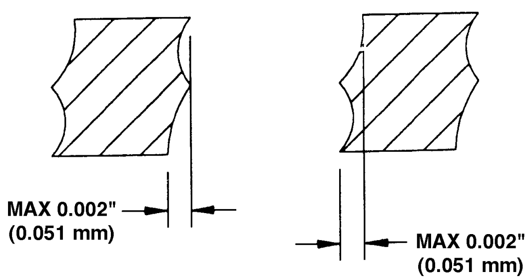

Figure 5
Overetching

lead twist — Angular rotation of the bond fingers (see Figure 6).

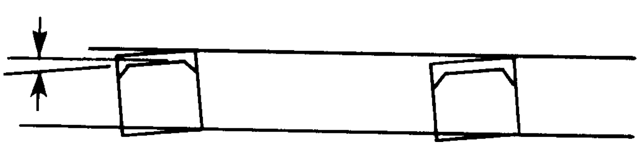

Figure 6
Lead Twist

offset alignment accuracy — The top to bottom alignment accuracy of the etched leadframe operation (see Figure 7).

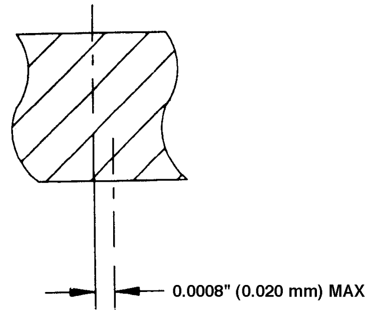

Figure 7
Etched Offset

pits — Shallow surface depressions or craters in the leadframe material (see Figure 8).

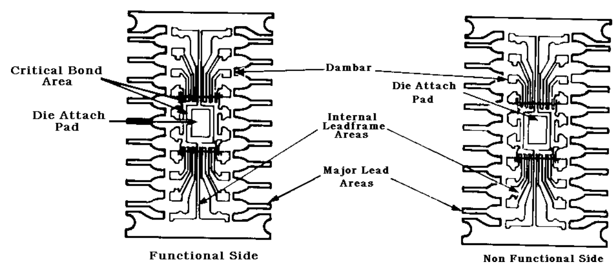

Figure 8
Pits

resist breakdown — Etching under the edges of the resist causing more than a standard undercut.

undercut — Bevelled edge caused by the etchant attacking the metal laterally as well as vertically (see Figure 4).

4 Ordering Information

Purchase orders for leadframes for plastic molded semiconductor packages furnished to this specification shall include the following items:

1. Drawing number and revision level
2. Material
3. Number of leads
4. Material certification
5. Number of units/strip
6. Plating requirements
7. Packaging and marking (see Section 8)

5 Dimensions

See applicable leadframe drawing as referred to in the ordering information.

6 Defect Limits and Parameters (see SEMI G10 to Measure)

6.1 *Minimum Flat Wire Bonding Area* — 0.203 mm (0.008") or 80% of nominal lead width, whichever is greater in width and 0.635 mm (0.025") in length. Undercut is an unavoidable process of etching. The above parameters are applicable only so long as the flat surface area is obtainable using the formula of Figure 4. The "radiusing" effect of the etching process will round off the tips and, therefore, the length of the flat area should be measured by starting back from the tip 0.254 mm (0.010").

NOTE: 0.008" flat is desirable. In order to achieve 0.008" flat, on 0.010" thick material, it is necessary to have a design width of 0.022" center to center, giving a 0.012" wide lead and 0.010" wide space.

6.2 Horizontal Lead Spacing and Location

6.2.1 Spacing between leads to be 0.152 mm (0.006") minimum after plating.

6.2.2 Metal to metal clearance (Dimension "W" Figure 7) minimum clearance shall be the greater of 0.152 mm (0.006") or the drawing dimension "W" minus 0.102 mm (0.004"). In determining dimension "W," the tolerance limits (max. vs. min.) shown on the drawing shall be used in the calculation.

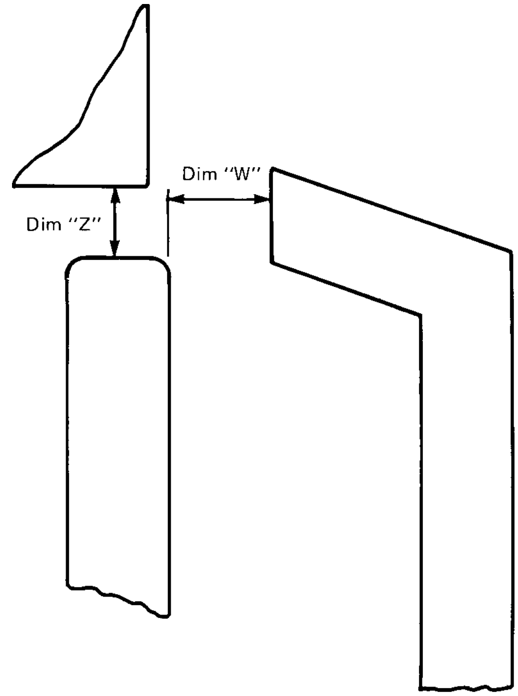

Figure 7
Metal to Metal Clearance

6.3 *Lead Twist* — Not to exceed 2° 30' or 0.0004" (0.010 mm) per 0.010" (0.254 mm) of lead width.

6.4 *Die Attach Pad Tilt & Flatness*

6.4.1 *Tilt* — 0.001" (0.025 mm) maximum per 0.100" (2.54 mm) of length or width in the undepressed state and 0.002" (0.050 mm) max per 0.100" (2.54 mm) of length or width in the depressed state when measuring from corner to corner. The corners are defined as 0.005" (0.127 mm) from each edge.

6.4.2 *Flatness* — 0.0004" (0.010 mm) maximum difference per 0.100" (2.54 mm) of length or width when measuring from center to average of four corners. The corners are defined as 0.005" (0.127 mm) from each edge.

6.5 *Die Attach Pad Offset or Depression* — (if applicable) — ± 0.002" (0.050 mm) as measured from the center of the pad to a point on the bar pad support strip. The nominal recommended offset is 0.015" (0.381 mm).

6.6 *Lead and Die Attach Pad Coplanarity* — See SEMI G10 for measurement procedure.

6.6.1 *Lead Planarity* — The lead tips as measured in the center of the flat wirebonding area must be within the following tolerances of the "Z" plane. Use Table 1 tolerances for untaped frames and Table 2 tolerances for taped frames.

Table 1 Tolerances for Untaped Frames

No. of Leads	*Strip Width*	*Lead Tip Coplanarity*
8 - 16	600"–1.000" (15.24 mm–25.4 mm)	+ 0.004"/-0.004" (0.101 mm)
18 - 22	1.070"– 1.020" (27.18 mm–25.91 mm)	+ 0.005"/-0.005" (0.127 mm)
22	1.270"–1.300" (32.26 mm– 33.02 mm)	+ 0.0065"/-0.0065" (0.165 mm)
24	1.470"–1.500" (37.34 mm–38.10 mm	+ 0.0075"/-0.0075" (0.191 mm)
28	1.670"–1.700" (42.42 m–43.18 mm)	+ 0.0085"/-0.0085" (0.216 mm)
40 & up	2.270"–2.300" (57.66 mm–58.42 mm)	+ 0.015"/-0.007" (+0.381 mm/-0.178 mm)

Table 2 Tolerances for Taped Frames

No. of Leads	*Strip Width*	*Lead Tip Coplanarity*
28	1.670"–1.700" (42.42 mm–43.18 mm)	+0.007"/-0.005" (+187 mm/-0.127 mm)
40 & up	2.270"–2.300" (57.66 mm–58.42 mm)	+0.010"/0.005" (+0.254 mm/-0.127 mm)

NOTE: It is recommended that 40 leads and more be taped prior to bonding.

6.6.2 *Die Attach Pad Planarity*

6.6.2.1 The die attach pad when measured at the center must be within the tolerances of the "Z" plane as shown in Table 3.

Table 3 Pad Planarity Tolerances

No. of Leads	*Pad Planarity*
8 - 16	+0.003"/-0.005" (+0.076 mm/-0.127 mm)
18 - 20	+0.006"/-0.003" (+0.152 mm/-0.076 mm)
22 - 40	+0.006"/-0.003" (+0.152 mm/-0.076 mm)
48	+0.006"/-0.003" (+0.152 mm/-0.076 mm)
64	+0.006"/-0.003" (+0.152 mm/-0.076 mm)

6.6.2.2 Die attach pads utilizing the four point tie design (support bars to both dambars) shall meet ± 0.002" (0.051 mm) of the "Z" plane.

6.7 *Material* — Thickness shall be as shown in Table 4.

Table 4 Material Thickness

Parameters	0.010" (0.254 mm)	0.015" (0.381 mm)	0.020" (0.508 mm)
Thickness	± 0.0003" (0.0076 mm)	± 0.0004" (0.0102 mm)	± 0.0005" (0.0127 mm)
Strip Width			
2.0" (50.8 mm)	± 0.002" (0.051 mm)	± 0.002" (0.051 mm)	± 0.002" (0.051 mm)
2.0" (50.8 mm)	± 0.003" (0.076 mm)	± 0.003" (0.076 mm)	± 0.003" (0.076 mm)

6.8 *Crossbow* — Shall not exceed the dimensions given in Table 5. If a certain width is not shown, 1% of the leadframe width shall apply.

Table 5 Maximum Crossbow Dimensions

No. of Leads	*Strip Width*	*Max. Crossbow*
8	0.600" (15.24 mm)	0.005" (0.127 mm)
14 - 16	0.970"/1.00" (24.64 mm/25.40 mm)	0.005" (0.127 mm)
18	1.070"/1.100" (27.18 mm/27.94 mm)	0.005" (0.127 mm)
20	1.170"/1.200"(29.72 mm/30.48 mm)	0.010" (0.254 mm)
22	1.270"/1.300"(32.26 mm/33.02 mm)	0.010" (0.254 mm)
24	1.470"/1.500"(37.34 mm/38.10 mm)	0.010" (0.254 mm)
28	1.670"/1.700"(42.42 mm/43.18 mm)	0.010" (0.254 mm)
40	2.270"/2.300"(56.66 mm/58.42 mm)	0.010" (0.254 mm)
48+	2.400"/2.670"(60.96 mm/67.82 mm)	0.010" (0.254 mm)

6.9 *Progression* — Progression over the (# of) steps in the strip should be within ± 0.051 mm (0.002") and non-cumulative.

6.10 *Pits (Indentations)* — Pits and imperfections cannot affect leadframe strength regardless of size (see Figure 6).

6.10.1 *Critical Bond Area* — 0.635 mm (0.025") of the finger tips + 0.508 mm (0.020") border of die attach pad; nothing greater than 0.0005" (0.0127 mm) diameter × 0.0076 mm (0.0003") in depth; not more than 1 pit.

Application Note: There is a question regarding the ability of material suppliers to meet this specification. Revision of this specification is under review.

6.10.2 *Die Attach Pad* — Functional side inside 0.508 mm (0.020") border; nothing greater than 0.127 mm (0.005") diameter × 50% metal thickness in depth; not more than 2 pits.

6.10.3 *Die Attach Pad* — Nonfunctional side; nothing greater than .508 mm (0.020") × 50% of metal thickness in depth; not more than 3 pits; cannot affect leadframe strength regardless of size (i.e., pit cannot be located within 0.127 mm (0.50") of pad support bar attachments).

6.10.4 Internal leadframe areas where design width is 0.635 mm (0.025") or more, must be less than 0.381 mm (0.015") × 50% metal thickness in depth; if design width is less than 0.635 mm (0.025"), area must be 50% of design width. Cannot affect leadframe strength regardless of size.

6.10.5 *Major Lead Areas (outside dambar)* — Nothing greater than 0.127 mm (0.005") × 50% of metal thickness in depth; nothing greater than 0.254 mm (0.010") on shoulder above taper. Cannot affect leadframe strength regardless of size.

6.10.6 *Dambar* — Pit cannot extend all the way across the bar.

6.11 *Mold Locating Holes* — Conventional mold damage design dictates that gating is opposite pin #1; therefore, the mold locating holes must be in the rail adjacent to pin #1. In order to minimize gate flashing between the mold and the rail edge, a specific tolerance of ± 0.051 mm (0.002") is required from the centerline of the mold hole to the opposite rail edge.

6.12 *Strip Length* — Strip length cut off shall be within 0.005", lead tip to lead tip centerline (excluding rails). The rail cut off length shall be within + 0.635 mm (0.025") unless otherwise specified by the user.

7 Sampling

Sampling will be determined between supplier and purchaser.

8 Packaging and Marking

8.1 *Packaging* — Leadframes must be packaged in containers designed and constructed to prevent damage and/or contamination. Specific protection must be provided against crushing, exposure to moisture, and mixture gases.

8.2 *Marking* — The outer containers shall be clearly marked to identify the user stock number, user purchase order number, drawing number, supplier lot number, and reel numbers within the carton. Additional information required should be specified by the user.

SEMI G20-96
SPECIFICATION FOR LEAD FINISHES FOR PLASTIC PACKAGES (ACTIVE DEVICES ONLY)

1 Purpose

This specification defines lead finishes for plastic packages (e.g., single-in-line, dual-in-line, quad-in-line) utilizing leadframes with SEMI specified leadframe materials.

2 Scope

This specification defines the composition, properties, and limits and refers to the appropriate tests for utility.

3 Referenced Documents

Unless otherwise specified, the following standards and specifications, with appropriate issue letter at time of order entry, form a part of this specification to the extent, and for the purpose, specified herein.

3.1 *SEMI Specifications*

SEMI G4 — Specification for Integrated Circuit Leadframe Materials Used in the Production of Stamped Leadframes

SEMI G18 — Specification for Integrated Circuit Leadframe Material Used in the Production of Etched Leadframes

SEMI G55 — Test Method Measurement of Silver Plating Brightness

SEMI G56 — Test Method Measurement of Silver Plating Thickness

3.2 *ASTM Specifications*[1]

B 487 — Measuring Metal and Oxide Coating Thickness by Microscopical Examination of Cross Section

B 545 — Standard Specification for Electrodeposited Coatings of Tin

B 567 — Measurement of Coating Thickness by the Beta Backscatter Principle

B 568 — Measurement of Coating Thickness by X-Ray Spectrometry

E 1B 571 — Adhesion of Metallic Coatings

E 10 — Standard Test Method for Brinell Hardness for Metallic Materials

E 384 — Standard Test Methods for Microhardness of Materials

3.3 *Federal Specifications*[2]

QQ-S-365 — Silver Plating, Electrodeposited, General Requirements for

QQ-S-571 — Solder, Tin Alloy: Tin Lead Alloy, and Lead Alloy

3.4 *Military Specifications*[2]

MIL-G-45204 — Gold Plating, Electrodeposited

MIL-P-81728 — Plating, Tin Lead, Electrodeposited

MIL-STD-883 — Test Methods and Procedures for Microelectronics

MIL-T-10727 — Tin Plating; Electrodeposits or Hot-Dipped, for Ferrous and Non-Ferrous Metals

4 Application

4.1 Table 1 lists recommended finishes for copper and nickel/iron alloys.

4.1.1 Silver is approved as a lead finish for all alloys but only for internal processing. When shipped to a customer, silver must be removed and replaced by tin lead.

4.1.2 Gold plate is usable in socketed applications as well as in soldered applications. Hardness, grain size, and other properties shall be specified on the procurement drawing.

4.1.3 Solder, as used in this specification, refers to tin lead as 63/37 or 60/40 unless otherwise specified and agreed upon between user and supplier, and stated on procurement drawings.

4.1.4 “Tinning” is a generic term (primarily used in user industries) and means hot solder dip (near 60/40 tin lead) and not an application of tin.

4.2 Composition, limits, mechanical and physical properties, and dimensions and tolerances for leadframes are stated in SEMI G4 and SEMI G18.

4.3 Lead finish details are stated in Section 5.

1 American Society for Testing Materials, 100 Barr Harbor Drive, West Conshohoken, PA 19428-2959

2 Military Standards, Naval Publications and Forms Center, 5801 Tabor Ave., Philadelphia, PA 19120

5 Lead Finish

5.1 Tin Electroplate

5.1.1 *Composition* — The tin shall not be less than 99.8% pure tin and shall not contain more than 0.1% carbon. The deposit is Type I as defined in MIL-T-10727.

Table 1 Alloys

	Finish Iron Alloys	*Finish Copper Alloys*
Tin MIL-T-10727		
Tin (over base metal)	X	X
Acceptable Undercoats		
1. Copper	X	X
2. Nickel	X	X
Tin Lead (Sn/Pb)		
MIL-P-81728		
Tin Lead (over base metal)	X	X
Sn/Pb

2. Copper Flash	X	
Silver QQ-S-365		
Silver (over base metal)	X	X
Acceptable Undercoats		
1. Copper	X	
2. Gold		X

5.1.2 *Characteristics* — The procedure used for evaluating the tin coating and the general requirements for the coating shall comply with ASTM B 545 or the latest current revision, except where noted below.

5.1.3 *Thickness* — The plated coating as measured on the major flat of the leads shall be a minimum of 5 micrometers (200 microinches).

5.1.4 *Appearance* — The surface texture of the tin shall be non-reflective matte finish.

5.1.5 *Hardness* — None specified.

5.1.6 *Preservation* — Preservation coating, if desired and agreed upon by user and supplier, is acceptable. (Example: Stearic acid solution in xylol as defined in MIL-T-10727.)

5.2 *Tin Lead (SnPb) Electroplate*

5.2.1 *Composition* — Major constituents shall be tin lead with minor impurities. Range of major constituents shall be:

Tin	60%—95%
Lead	5%—40%

5.2.2 *Purity and Application* — Per MIL-P-81728.

5.2.3 *Thickness* — Shall be a minimum of 5 micrometers (200 microinches) measured on the major flat of the leads.

5.2.4 The surface of the tin lead shall be non-reflective matte finish.

5.2.5 *Hardness* — None specified.

5.3 *Tin Lead Solder-Dip*

5.3.1 *Composition* — 60/40 or 63/37.

5.3.2 *Purity* — As per Federal Specification QQ-S-571.

5.3.3 *Thickness* — Shall be a minimum of 5 micrometers (200 microinches) as measured on the major flat of the leads.

5.3.4 *Process Conformance* — Solder coating is applicable as shown in Table 1. In addition, the coating is acceptable as follows:

1. Over the electroplated tin or tin lead as per Section 5.1 or 5.2.
2. Over the electroplated silver as per Section 5.4.
3. Over the electroplated gold as per Section 5.5.

5.3.5 *Appearance* — Surface shall be smooth and continuous.

5.3.6 *Hardness* — None specified.

5.4 *Silver Electroplate*

5.4.1 *Composition* — Silver electroplate shall be semi-bright, Type II as per Federal Specification QQ-S-365, Grade B, (without supplementary tarnish resistant treatment).

5.4.2 *Thickness* — Shall be a minimum of 1.25 micrometers (50 microinches) as measured on the major flat of the leads, in accordance with SEMI G56.

5.4.3 *Appearance* — Smooth and continuous and semi-bright with minimum discoloration as measured, in accordance with SEMI G55.

5.4.4 *Hardness* — Hardness shall be between 90 and 135 on the Brinell Hardness Scale, in accordance with ASTM E 10.

5.4.5 *Additional Processing*

5.4.5.1 Due to chemical reactions, silver electroplated surfaces should be protected from sulfur and sulfur bearing materials such as note paper, cardboard, and other like materials. Sulfur-free papers shall be used for packing.

5.4.5.2 Prior to shipment to a user, devices with silver electroplated leads shall have the silver removed and replaced with tin lead coated leads, unless accepted by contract.

5.5 *Gold Electroplate*

5.5.1 *Composition* — Gold plating shall be applied in accordance with MIL-G-45204 in any and all of the following grades depending on application.

Type I	- 99.7 Percent minimum
Type II	- 99.0 Percent minimum
Type III	- 99.9 Percent minimum

NOTE 1: Type II is suitable for socketing application only.

5.5.2 *Thickness* — Shall be a minimum of 1.25 micrometers (50 microinches) as measured on the major flat of the leads.

5.5.3 *Appearance* — Appearance of surface shall be smooth and continuous. Attributes and defects are specified in MIL-G-45204 (workmanship paragraph).

5.5.4 *Purity* — Composition limits are as specified in Section 5.5.1 above. Individual metallics in the deposit shall not exceed 0.1%. Metallic hardening agents, purposely added to adjust a plating bath to specified hardness, are not considered as impurities.

5.5.5 *Hardness* — Depending on Type and Application, hardness is specified, using Knoop indenter in the following categories (testing shall be in accordance with ASTM E 384):

Type	*Grade*	*Hardness (Knoop)*
I	A	90 max
	B	91—129
	C	130—200
II	B	91—129
	C	130—200
	D	201 and over
III	A	90 max

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI G21-94
SPECIFICATION FOR PLATING INTEGRATED CIRCUIT LEADFRAMES

1 Preface

1.1 *Purpose* — This specification details the requirements for plating layers on leadframes intended for use in platic semiconductor packages. It is intended as a design guideline.

1.2 *Scope* — The specifications and test procedures detailed in this document apply to all plating applied to the internal section of leadframes. External leadframe finishes are not included.

1.3 *Units* — U.S. Customary (inch-pound) or SI units may be used at the customer's discretion. This specification uses U.S. Customary units as the prime unit.

2 Referenced Documents

2.1 *Applicable Documents* — To avoid conflicts, the order of precedence when ordering plated leadframes shall be as follows:

Purchase Order

Customer's Leadframe Drawing

This Specification

Referenced Documents

Related Documents

2.2 *Referenced Documents*

2.2.1 *SEMI Specifications*

SEMI G4 — Integrated Circuit Leadframe Materials used in the Production of Stamped Leadframes

SEMI G18 — Materials Used in the Production of Etched Leadframes for Semiconductor Devices

SEMI — All leadframe specifications

2.2.2 *ASTM Specifications*[1]

B 847 — Test Method for Measurement of Metal and Oxide Coating Thicknesses by Microscopic Examination of a Cross-Section

B 567 — Method for Measurement of Coating Thickness by the Beta Backscatter Method

B 568 — Method for Measuring Coating Thickness by X-Ray Spectrometry

E 384 — Standard Test Method for Microhardness of Materials

F 1269 — Test Methods for Destructive Shear Testing of Ball Bonds

2.2.3 *Military and Federal Specifications*[2]

MIL-C-14550 — Copper Plating, Electrodeposited

MIL-G-45204 — Gold Plating, Electrodeposited

MIL-T-10727 — Tin Plating, Electrdeposits or Hot Dipped, for Ferrous and Non-Ferrous Metals

MIL-STD-883 — Test Methods and Procedures for Microelectronics

QQ-N-290 — Nickel Plating, Electrodeposited

QQ-S-3651 — General Requirements for Electrodeposited Silver Plating

2.3 *Related Documents*

2.3.1 *Military and Federal Specifications*

MIL-P-81728 — Plating Tin/Lead (Sn/Pb) Electrodeposited

MIL-STD-105 — Sampling Procedures and Tables for Inspection by Attributes

2.3.2 *ISO Standards*[3]

ISO-3497 — Metallic Coating Measurement of Coating Thickness, X-Ray Spectrometry Method

3 Terminology

3.1 *finish (plating)* — The final plating layer.

3.2 *resin bleed-out (die attach)* — The surface creep of a resin used for die attach beyond the outer perimeter of the bulk of the resin (filler). For a given resin formulation, the resin creep may be exacerbated by the micro-structure and cleanliness of the die attach surface.

3 ANSI, 1430 Broadway, New York, NY 10018

4 Ordering Information

Purchase orders for material furnished to this specification shall include the following information:

4.1 Leadframe drawing showing the areas to be plated and tolerances for the location.

4.2 *Plating Metal, Type, and Grade* — Underplate and finish plate.

4.3 Plating(s) thickness and tolerance.

4.4 Certification or Test Report requirements.

4.5 Reference to this specification.

4.6 Any additions to or variations from this specification.

5 Materials

5.1 *Base Material* — See SEMI G4 and G18 for leadframe base metal specifications.

5.2 *Underplates* — When underplates are specified, the materials specified in Table 1 shall be used.

Table 1 Underplates

Platings	*Type Grade*	*Specifications*	*Specifications*
Nickel			QQN-290
Copper			MIL-C-14550
Gold	III	A	MIL-G-45204
Silver	I, II, III	B	QQ-S-365

5.3 *Finish/Underplates* — The recommended finish plating options for copper and nickel-iron alloys and the suggested underplates are show in Table 2.

Table 2 Undercoat Finishes

*Copper strike may be used under nickel.

6 Sampling

6.1 The sampling plan shall be agreed between user and supplier.

7 Equipment

7.1 Beta Backscatter system.

7.2 Die Attach equipment.

7.3 Eutectic Die Attach heater block or hot plate capable of 450°C ± 10°C.

7.4 Microscope 10–30× magnification with 45° lighting.

7.5 Micro Cross-Section equipment.

7.6 Toolmaker's Microscope

7.7 Wire Bond equipment

7.8 X-ray Fluorescence system

7.9 Solderability equipment

8 Incoming Inspection

If incoming inspection is performed, materials shall be inspected in the following sequence:

8.1 Visual Inspection

8.2 Surface Finish

8.3 Plating Area and Thickness

8.4 *Plating Quality* — Heat Test and Adhesion Test

8.5 Functional Tests

8.5.1 Die Attach

8.5.2 Wire Bond

8.5.3 Solderability

8.6 Plating Hardness

9 Test Methods

9.1 Visual Inspection

9.1.1 Visually inspect the plated area using a binocular microscope, at 10×–30× magnification for the following rejectable conditions.

9.1.1.1 Any bare spots or missing plating in critical areas as defined by the coined areas or minimum flat wire bond area in the appropriate leadframe specification.

9.1.1.2 Any peeling or blistered plating.

9.1.1.3 Any nodules in critical area as defined in 9.1.1.1.

Note 1: Nodules not exceeding 0.0005" (0.0381 mm) in a surface dimension and 0.0005" (0.0127 mm) in height in non-critical areas are allowed providing there are no more than one per internal lead finger or six (6) per leadframe.

9.1.1.4 Any pits which exceed 0.0003" (0.008 mm) in depth or 0.0005" (0.0127 mm) in a surface dimension in critical areas or 0.001" (0.0254 mm) in depth or 0.002" (0.051 mm) in a surface dimension in non-critical areas.

9.1.1.5 Any scratches or scrapes in the metallization plating which expose underplate or base material.

9.1.1.6 Any scratches or scrapes in critical areas which cause a build up of material in excess of 0.0005" (0.0127 mm) in height.

9.1.1.7 Any foreign material, contamination, oxidation or tarnish.

9.2 *Surface Finish*

9.2.1 The surface finish or brightness shall be inspected according to procedures agreed upon between vendor and customer.

9.3 *Plating Area and Thickness*

9.3.1 *Plating Area*

9.3.1.1 Using a toolmaker's microscope determine if spot plated areas meet the requirements of the leadframe drawing for position and size tolerance.

9.3.2 *Thickness*

9.3.2.1 Plating thickness shall be measured at locations agreed between vendor and customer according to procedures detailed in ASTM B 487, ASTM B 567, or ASTM B 568.

Note 2: Only use ASTM B 487 for thicknesses greater than 100 micro-inches (0.0025 mm).

9.4 *Plating Quality* — Heat Test and Adhesion Test.

9.4.1 *Copper Plate* — Test according to procedures agreed between vendor and customer.

9.4.2 *Gold and Silver Plate*

9.4.2.1 Submit gold plated samples to 450°C + 10°C for two (2) minutes in air on a die attach heater block or hot plate and silver plated samples to 300° C + 10° C with the same conditions.

Note 3: For silver plating thicknesses less than 100 micro-inches (0.0025 mm), heat testing is not valid unless an alternate time and temperature is agreed upon between the vendor and the customer.

9.4.2.2 Visually inspect the plating under the microscope set at 10× magnification for blistering, peeling, and discoloration.

Note 4: For gold plating, discoloration after the heat testing is only allowable if the fold plate thickness is less than 20 micro-inches (508 microns) by design.

Note 5: 30× magnification may be used for confirmation.

9.4.2.3 Place a strip of tape across the plated area. Press firmly with fingertips or another smooth object.

9.4.2.4 Peel the tape quickly off the plated surface. If there is any plating on the tape the component shall be rejected.

9.4.3 *Nickel Plate* — Test according to procedures agreed between vendor and customer.

9.4.4 *Palladium Plate* — Test according to procedures agreed between vendor and customer.

9.4.5 *Tin Plate* — Test according to procedures agreed between vendor and customer.

9.5 *Functional Tests*

9.5.1 *Die Attach*

9.5.1.1 Sample die, using a resin agreed between vendor and customer, shall be attached to plated leadframes.

9.5.1.2 Die shear tests shall be performed per MIL-STD-883, Method 2019 or to a method agreed between vendor and customer.

9.5.1.3 Resin bleed-out shall not exceed 0.010" (0.254 mm).

Note 6: Control samples from a previously accepted leadframe lot shall be tested at the same time, using the same resin batch, for comparison.

9.5.2 *Wire Bond*

9.5.3 Sample leadframes shall be bonded using wire and procedures agreed between vendor and customer.

9.5.3.1 Wires and bonds shall be tested according to MIL-STD-883, Method 2011, and/or ASTM F 1269 by agreement between vendor and customer.

9.5.4 Tin Plate Solderability

9.5.5 The solderability or alloying capability of the tin plate shall be evaluated per procedures agreed between vendor and customer.

9.6 *Plating Hardness*

9.6.1 Where required for verification of results obtained in other tests, the plating hardness shall be measured per ASTM E 384.

10 Certification

10.1 Upon request by the customer in the purchase order, a vendor's certification that the plating was performed and tested in accordance with this specification, together with a report of the test results, shall be furnished at the time of shipment. This certification does not remove the vendor's responsibility for discrepant product subsequently found by the customer.

10.2 When certification is requested, the following information shall be supplied as a minimum requirement:

10.2.1 Vendor Name

10.2.2 Purchase Order Number

10.2.3 Vendor Lot Number

10.2.4 Customer Part Number

10.2.5 Plating Type, Grade and Measured Thickness for Under and Finsh Plates

10.2.6 Plating hardness if agreed between vendor and user.

11 Packaging and Marking

11.1 *Packaging*

11.1.1 Shipping containers and materials shall be suitably selected to provide the material with protection from normal transportation damage risks which include crushing, abrasion, spillage, and exposure to moisture and other corrosive gases. The inner packing materials may be further specified by the customer for cleanliness and non-tarnishing issues.

11.2 *Marking*

11.2.1 *Internal Packages* — Each internal package shall be marked as follows:

Vendor's Name

Customer's Part Number

Customer's Order Number

Vendor's Specification Number and Customer's, if appropriate

Manufacturing Lot Number

Quantity

Date of Manufacture

11.2.2 *External Packages*

Customer's Specification Number

Customer's Order Number

Quantity

Shipping Date

Any specific instructions for receiving dock personnel if requested on the purchase order

12 Discrepancy Material

12.1 Material rejected at incoming inspection shall be segregated and tagged as rejectable.

12.2 The vendor shall be informed and the returned goods policy activated.

Note 7: Samples showing the defects shall be identified for the vendor. If the vendor wishes to see the samples before return of the complete shipment, the material shall be stored by the customer in a manner to prevent further damage or deterioration.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI G22-1296
SPECIFICATION FOR CERAMIC PIN GRID ARRAY PACKAGES

1 Purpose

This specification defines the acceptance criteria for cofired ceramic pin grid array packages.

2 Scope

This specification includes the visual, dimensional, and functional requirements for the ceramics PGA package.

3 Referenced Documents

3.1 *Military Standards*[1]

MIL-G-45204 — Gold Plating, Electrodeposited

MIL-I-23011 — Iron Nickel Alloys for Sealing to Glasses and Ceramics

MIL-PRF-38535 — Integrated Circuits (Microcircuits) Manufacturing, General Specification for

MIL-STD-105 — Sampling Procedures and Tables for Inspection by Attributes

MIL-STD-883 — Test Methods and Procedures for Microelectronics

MIL-STD-1835 — Interface Standard for Microcircuit Case Outlines

MIL-STD-7883 — Brazing

QQ-N-290A — Nickel Plating

3.2 *Other Documents*

ANSI Y14.5[2] — Dimensioning and Tolerancing

JEDEC Pub. No. 95[3] — Registered and Standard Outlines for Semiconductor Devices

4 Terminology

4.1 *blister (bubble) ceramic* — Any separation within the ceramic which does not expose underlying ceramic material.

4.2 *blister (bubble) metal* — Any localized separation within the metallized or between the metallization and ceramic which does not expose underlying metal or ceramic material.

4.3 *braze* — An alloy with a melting point equal to or greater than 450°C.

4.4 *burr* — An adherent fragment of excess parent material, either horizontal or vertical, adhering to the component surface.

4.5 *chip* — A region of ceramic missing from the surface or edge of a package which does not go completely through the package. Chip size is given by its length, width, and depth from a projection of design plan form (Figure 1).

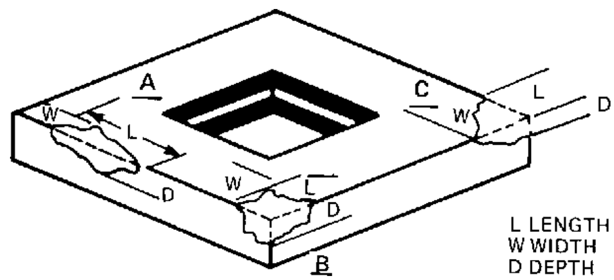

Figure 1
Chip Illustration

4.6 *cofired* — A process or technology for manufacturing products in which the ceramic and refractory metallizations are fired simultaneously.

4.7 *contact pad* — That metallized pattern that provides mechanical or electrical connection to the external circuitry.

4.8 *crack* — A cleavage or fracture that extends to the surface of a package. It may or may not pass through the entire thickness of the package.

4.9 *delamination* — The separation of the individual layers of the ceramic.

4.10 *die attach area* — A dimensional outline designated for die attach.

4.11 *discoloration* — Any change in the color of the package plating or metallization as detected by the unaided eye which normally appears after the application of heat per Section 8.7.1.

4.12 *flatness* — The allowable deviation of a surface from a reference plane. The tolerance zone is defined by two parallel planes within which the surface must lie.

4.13 *footprint* — Pin pattern.

4.14 *foreign material* — An adherent particle other than parent material of that component.

1 Military Standards, Naval Publications and Form Center, 5801 Tabor Ave., Philadelphia, PA 19120

2 ANSI, 1430 Broadway, New York, NY 10018

3 JEDEC, 2500 Wilson Blvd., Arlington, VA 22201-3834

4.15 *isolation gap* — Metal-free space between conductive areas.

4.16 *layer* — A dielectric sheet with or without metallization that performs a discrete function as part of the package.

4.17 *peeling (flaking)* — Any separation of metallization from the base material that exposes the base material.

4.18 *pit* — Any unspecified depression in the package.

4.19 *projection* — An adherent fragment of excess parent material on the component surface.

4.20 *pullback* — A dimension covering the linear distance between the edge of the ceramic and the first measurable metallization (see Figure 2).

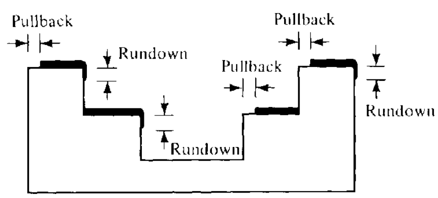

Figure 2
Metallization Misalignment

4.21 *rundown* — The linear distance down a vertical surface from the top to the point of maximum metallization overhang (see Figure 2).

4.22 *seal area* — A dimensional outline area designated for either metallization or bare ceramic to provide a surface area for sealing.

4.23 *seating plane* — As defined by the standoff features or the package base plane if no standoff is used (see Figure 3).

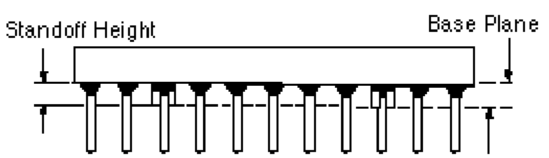

Figure 3
Seating Plane

4.24 *standoff* — The designed separation between the base plane and the seating plane created by a physical feature. Standoff use, configuration, and placement is optional (see Figure 3).

4.25 *terminal* — Metallization at the point of electri cal contact to package internal circuitry.

4.26 *TIR* — Total indicator reading.

4.27 *voids* — An absence of refractory metallization, braze, or plating material from a designated area greater than 0.002" (0.051 mm) in diameter.

5 Ordering Information

Purchase orders for pin grid array packages furnished to this specification shall include the following items:

1. Drawing number and revision level
2. Certification requirements
3. Quantity
4. Reference to this document
5. Any exceptions to print or specifications

6 Dimensions and Permissible Variations

The dimensions of the pin grid array package shall conform to the SEMI Standards or to the customer drawing and be within the outline of the appropriate JEDEC standard. Refer to MIL-PRF-38535 and MIL-STD-1835.

7 Material Parameters

The definitions, defects, and functional testing described in this specification relate directly to a nominal package made with the following materials. They may also be applicable to similar pin grid array packages made with other materials.

7.1 *Ceramic Properties*

7.1.1 *Materials* — Alumina content 90% minimum. Beryllia content to be determined.

7.1.2 *Color* — Dark or white.

7.2 *Metal Properties*

7.2.1 Metallized circuits and areas shall be refractory metal tungsten, molybdenum, or an approved equivalent, 0.0003" (0.00762 mm) minimum thickness.

7.2.2 Finish shall be per MIL-PRF-38535 and MIL-STD-1835; Nickel Plating (if designated) shall be per QQ-N-290A, 50 µ"–350 µ" (0.0013 mm–0.00889 mm). Gold plating shall conform to MIL-G-45204, Type III and 50 µ"–225 µ" (0.0013 mm–0.00508 mm).

7.2.3 Braze shall be per MIL-STD-7883.

7.2.4 *Pin Material* — Iron nickel cobalt alloy per MIL-PRF-38535 and MIL-STD-1835, Type A (Kovar). Iron nickel alloy per MIL-PRF-38535 and MIL-STD-1835, Type B (Alloy 42). Phosphor bronze per ASTM B159.

8 Defect Limits

A magnification of 10× to 30× shall be used to inspect the packages unless otherwise specified.

8.1 *Ceramic*

8.1.1 *Cracks* — Per MIL-STD-883, Method 2009.

8.1.2 *Chips* — (See Figure 1.)

8.1.2.1 *Edge* — 0.100" (2.54 mm) length × 0.030" (0.762 mm) width × 0.020" (0.508 mm) (see Figure 1, A).

8.1.2.2 *Corner* — 0.030" (0.762 mm) length × 0.030" (0.762 mm) width × 0.030" (0.762 mm) (see Figure 1, B).

8.1.2.3 Chips cannot encroach upon contact pad or expose any buried metallization.

8.1.2.4 *Seal Area* — 0.060" (1.52 mm) length × 0.020" (0.508 mm) width × 0.020" (0.508 mm) depth maximum.

8.1.2.5 Chips cannot reduce the seal width by more than 1/3 of the design width.

8.2 *Package Flatness* — 0.004 inch/inch (0.004 mm/mm) maximum.

8.2.1 *Seal Area Flatness*

Seal Area Size	*Seal Area Flatness (TIR)*
0.000" – 0.500" (0 – 12.7 mm)	0.002" (0.51 mm) Maximum
0.501" – 0.750" (12.72 – 19.05 mm)	0.003" (0.076 mm) Maximum
0.751" & greater (19.07 mm)	0.004" (0.101 mm) Maximum

8.2.2 *Die Attach Area Flatness*

Die Attach Area Flatness	*Die Attach Area Flatness (TIR)*
0.000" – 0.500" (0 – 12.7 mm)	0.002" (0.051 mm) Maximum
0.501" – 0.750" (12.72 – 19.05 mm)	0.0035" (0.088 mm) Maximum

8.3 *Metallization Voids* — (Voids greater than 0.003" (0.075 mm) should be considered.)

8.3.1 *Seal Area* — Maximum number of three (3) voids per seal ring allowed. The maximum void dimension is 0.010" (0.254 mm) and voids must be separated by a minimum of 0.030" (0.762 mm).

8.3.2 *Wire Bond Finger* — Be free of voids or bare spots in the bonding area as defined by customer drawing.

8.3.3 *Die Attach Area* — Three (3) voids allowed, maximum 0.010" (0.254 mm) diameter voids separated by a distance greater than 0.010" (0.254 mm). Voids within 0.015" (0.381 mm) of die attach cavity wall shall not be considered as the basis for rejection.

8.3.4 *Braze Metallization* — A 0.010" (0.254 mm) maximum diameter void is acceptable, one (1) void per pad.

8.4 *Metallization Misalignment* — (See Figure 2.)

8.4.1 *Metallization Rundown* — Internal cavity not to exceed 0.010" (0.254 mm) maximum.

8.4.2 *Wire Bond Finger Pullback* — 0.010" (0.254 mm) maximum.

8.4.3 *Wire Bond Finger Rundown* — Metallization rundown not to exceed 0.010" (0.254 mm) maximum.

8.4.4 *Pattern Isolation* — Minimum shall not be reduced by more than 50% of the design.

8.5 *Pins*

8.5.1 *Pin Attachment* — The pin must be within the area of the braze pad (fillet seen on all sides). The pin must be located within 0.010" (0.254 mm) radius of true location with respect to all other pins.

8.5.2 Pins that are broken, missing, twisted, or bent more than 30 °.

8.5.3 Pin burrs greater than 0.005" (0.125 mm) in any direction.

8.6 *Plating*

8.6.1 Any visual evidence of plating defects such as blistering, peeling, voids, or stains.

8.6.2 Any plating damage such as scratches or marred areas that expose underlying base metal.

8.7 *Components (General)*

8.7.1 Any visual evidence of corrosion, contamination, or chemical stains on the package component.

8.7.2 Any protrusion, conductive, or non-conductive, that is more than 0.005" (0.125 mm) in height.

9 Sampling

Sampling size must meet the requirements of MIL-STD-105 or MIL-PRF-38535 and MIL-STD-1835, or as agreed to between vendor and customer. Single, double or multiple samples may be used per vendor and customer agreement.

10 Test Methods

10.1 *Mechanical, Electrical, and Thermal Test Methods* — Per MIL-STD-883 unless otherwise noted.

10.1.1 Gold plating and bake test of gold plated package shall be tested by placing parts on a calibrated heater per MIL-STD-883, Method 1008 (excluding temperature).

10.1.1.1 *Condition A* — 450 ± 10°C for two minutes in air, or

10.1.1.2 *Condition B* — 470 ± 10°C for one minute in nitrogen.

10.1.1.3 After cooling at room temperature the packages will be examined for the following criteria:

1. *Blisters* — None allowed at 10× magnification.
2. Any non-uniform color change of the gold at die attach pad. Discolorations within edges up to 0.015" (.381 mm) from the cavity wall is acceptable.
3. Any non-uniform color change of the bonding fingers, seal ring surface, or external pins is not acceptable.
4. There shall be no flaking or peeling of the package plating when viewed at 10x magnification.
5. Superficial stains left during drying or prior operations is not cause for rejection.
6. Plating adhesion tape test.

10.1.2 *Lead Pull* — Under the test condition of five (5) pounds ± one-quarter (1/4) pound pull at an angle of 20° or less from the pins vertical line, measured perpendicular to the package, there shall be no visible separation of the braze joint under 10x magnification. This excludes plating.

10.1.3 *Lead Fatigue* — Test per MIL-STD-883, Method 2004, Test Condition B2, Section 3.1.

10.2 *Functional Test Methods*

10.2.1 *Die Attach Quality* — Destructive die shear test post environmental testing per MIL-STD-883, Method 2019, Paragraph 3.2C.

10.2.2 *Wire Bond Quality* — Minimum pre-seal and post-seal bond strength test per MIL-STD-883, Method 2011, Test Condition D. Reject for bonds which cause plating to lift from the base metal of the bonding fingers or fail to meet minimum strength requirement.

10.2.3 *Solderability* — Test per MIL-STD-883, Method 2003 (omit aging).

10.2.4 *Insulation Resistance* — Test per MIL-STD-883, Method 1003, Condition D.

10.2.5 Hermetic and Environmental Testing per MIL-STD-883.

10.2.5.1 The hermetic integrity of the package must be maintained after all environmental testing. Hermetic checks shall comply with MIL-STD-883, Method 1014, Test Conditions A, B, C, or D.

10.2.5.2 Environmental testing shall include but not be limited to the following:

1. *Temperature Cycle* — MIL-STD-883, Method 1010, Condition C without heat sink; Condition B with heat sink.
2. *Thermal Shock* — MIL-STD-883, Method 1011, Condition C without heat sink; Condition B with heat sink.
3. *Centrifuge* — MIL-STD-883, Method 2001, Condition E. Y1 axis only — cavity up; Y2 axis only — cavity down (optional).
4. *Mechanical Shock* — MIL-STD-883, Method 2002, Condition B.
5. *Vibration* — MIL-STD-883, Method 2007, Condition A.

NOTE 1: Package applications requiring a heat sink attach will require the environmental test requirements (temp. cycle, shock, etc.) to be evaluated on an individual basis. The material, form factor, and method of attach used for heat sinks may result in severe stresses being induced on the package assembly during environmental testing. Actual accelerated test requirements should be based on the expected product application environment and may be less rigorous than those tests for packages without heat sinks.

11 Sequence of Events and Incoming Testing

During incoming inspection the sequence of testing shall be:

A. Visual

B. Dimensional

C. Functional (typical functional tests which may be applied):

   Die Attach

   Wire Bond

   Pre-seal wire pull

   Seal

   Heat sink attach (if applicable)

Environmental Test

Fine Leak — MIL-STD-883, Method 1014, Condition B

Gross Leak — MIL-STD-883, Method 1014, Condition C

Post-Seal Bond Pull

Radiography

Die Shear — MIL-STD-883, Method 2019

Solderability — MIL-STD-883, Method 2003

NOTE 2: An initial vendor qualification may be performed on the thermal and electrical characteristics of the package. The characteristics tested will be:

Insulation Resistance — MIL-STD-883, Method 1003, Test Condition D.

Thermal Dissipation — MIL-STD-883, Method 1012.

12 Packaging and Marking

12.1 *Packaging* — Containers selected shall be strong enough and suitably designed to provide maximum protection against crushing, spillage, and other forms of damage to the container or its contents to contamination from exposure to excessive moisture or oxidation by gases. Packaging materials shall be so selected to prevent any contamination of the ceramic components parts with fibers or organic particles.

12.2 *Marking* — The outer containers shall be clearly marked identifying the customer part number, customer purchase order number, drawing number (optional), quantity, date, and vendor lot number (optional).

SEMI G23-0996
TEST METHOD FOR INDUCTANCE OF INTERNAL TRACES OF SEMICONDUCTOR PACKAGES

NOTE: This entire document was revised in 1996.

1 Purpose

This test method describes the measurement method for the inductance of internal traces of semiconductor packages.

2 Scope

2.1 This test method is applicable for the measurement of package inductance that is greater than 0.5 nH.

2.2 This document describes the measurement of a pin grid array, one of the package types, as a sample.

2.3 This test method is also applicable to other types of packages.

2.4 The inductance in this document is limited to that of internal traces only and does not contain the portions contributed by the exposed areas such as pins and wires.

2.5 This document uses SI units.

3 Limitation

It is not practical to apply this test method for fine-pitch packages where traces or pads (point A of Figure 1) cannot be connected to with two probes.

4 Referenced Documents

None.

5 Terminology

5.1 *internal inductance (of packages)* — Inductance of the circuit that comprises the signal path starts from the shoulder or in the center of the outside lead (point A of Figure 1) and ends at the end of the lead on the cavity side of the lead (point B of Figure 1). The return path is made by tying all other traces (except for the target trace in the same electric potential) together. The target trace is tied to the return path at the bonding finger (see Figure 2).

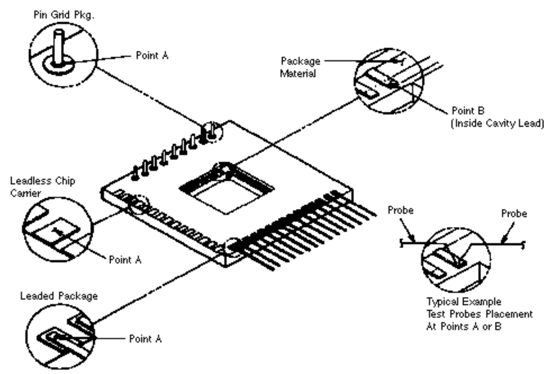

Figure 1
Internal Inductance Measurement

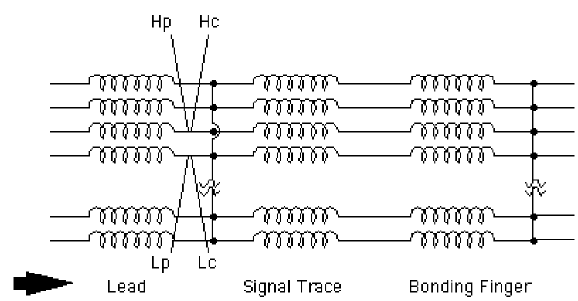

Figure 2
Concept of Internal Inductance

5.2 *four-point probe* — The probe consists of four coaxial measuring terminals, H_c (current high), H_p (potential high), L_c (current low) and L_p (potential low), to measure impedance. Independent coaxial cables are used between the package being measured and the measurement instrument to minimize the effect caused by mutual inductance (between terminals) and/or interferences from the measured signals (see Figures 3 and 6).

6 Summary of Method

Fabricate the package to be measured. Then measure the inductance of internal traces using the four terminal probe method.

7 Interference

7.1 It is desirable that an operator who is familiar with the measuring system, measuring method, and principles, conduct the actual measurement to get the best result.

7.2 To get an accurate measurement, maintain equal probe angle and distance.

8 Apparatus

8.1 *LCR Meter*

8.1.1 Four terminal probe attachment capability

8.1.2 Capable of measuring at the frequency of 10 MHz or higher

8.1.3 Measurement error of less than 0.1 nH for the measurement range more than 1 nH at the measurement frequency

8.2 *Four Terminal Probe* — See Figure 3.

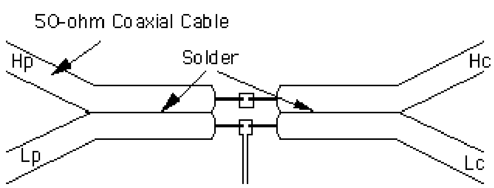

Figure 3
Configuration of Four Terminal Probe

8.2.1 *Residual Inductance* — less than 1 nH

9 Material

9.1 *Copper Plate*

9.1.1 *Plating* — gold

9.1.2 *Thickness* — 2 mm or thicker

9.2 *Insulator* — such as Teflon

9.3 *Silver Foil*

9.3.1 *Thickness* — around 50 µm

9.4 Solder or Conductive Paste

9.4.1 *Resistivity* — 10^{-4} Ω · m or less

10 Test Specimens

10.1 *Preparation of Sample* — Conduct the circuit by measuring the trace as a signal path and the rest, which has a different potential from this signal path, will be the return path, as follows:

10.1.1 All the bonding fingers shall be soldered or pasted together at the bond finger area to form a short circuit.

NOTE 1: The short circuit area shall be 0.5 mm from the tip of the bond fingers. The entire bond fingers shall not be short circuited (see Figure 4).

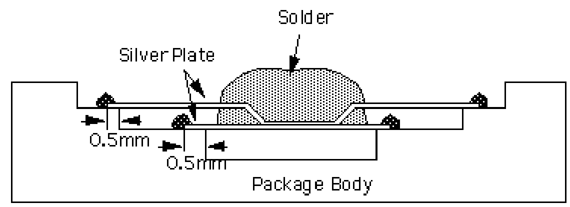

Figure 4
Sample Preparation (Part of Bonding Finger)

10.1.2 Short all pins or leads except for the ones with the same potential as the trace being measured.

NOTE 2: The location for the short circuit shall be as close as possible to the bottom of the pins or the braze pad of the leads to minimize the inductance caused by the pins or leads.

NOTE 3: In case of Pin Grid Array packages, it is recommended to press 50 µm thickness silver foil, which is the same size of package, through the pins. In case of Flat Packages, it is recommended to solder silver foil (or a copper foil) at the braze pads of the leads.

11 Preparation of Apparatus

Before starting the measurement, warm up the instruments as specified in the manual.

12 Calibration

Before starting the measurement, calibrate the instruments as specified in the manual.

13 Procedures

13.1 *Measurement of Residual Inductance*

13.1.1 Set the LCR meter to the inductance measurement mode.

13.1.2 Measure the inductance by conducting the four terminal probe on the gold plated copper plate as shown in Figure 5.

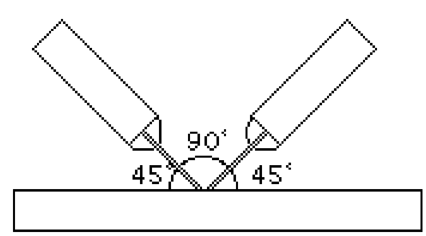

Figure 5
Measurement of Residual Inductance

NOTE 4: The angle between the potential terminal probe and the current terminal probe has to be maintained at a right angle (90°). This is to nullify the mutual interference caused by the magnetic flux.

13.2 *Measurement of the Resultant Inductance*

13.2.1 Place the sample on the insulator such as Teflon.

13.2.2 Set the probe at the bottom of the pin of the trace being measured and at the closest traces belonging to the short circuit as shown in Figure 6.

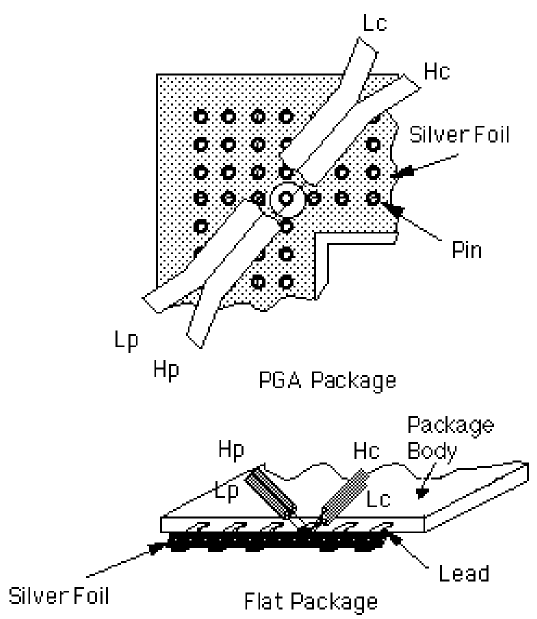

Figure 6
Probing Method

NOTE 5: The probes H_p and H_c are attached/placed onto the pins to be measured and the probes L_p and L_c are attached/placed onto the short circuit.

14 Calculation

14.1 The inductance of the internal trace is calculated as follows:

Internal Inductance (nH) = Measured Inductance — Residual Inductance

14.2 Round the second digit after the decimal point to the unit of 0.1 nH.

15 Report

The following information shall be reported:

- Brief description of the package
- Measurement instrument or system
- Measurement frequency
- Measurement pin numbers
- *Inductance* — Raw data as well as the average in case of multiple measurements.

16 Accuracy

Using the same samples, four different packaging manufactures were tested. The following results were obtained:

Repeatability — ± 0.2 nH

Reproductibility — ± 0.5 nH

SEMI G24-89
TEST METHOD FOR MEASURING THE LEAD-TO-LEAD AND LOADING CAPACITANCE OF PACKAGE LEADS[1]

1 Purpose

This document defines the equipment, materials, and procedures used to measure the lead-to-lead and loading capacitance of package leads. Semiconductor packages are shown as examples; however, other packaging elements can be measured by this method.

2 Equipment and Materials

2.1 Capacitance meter which uses a two probe plus guard method with two coax cables, or a meter which utilizes a four probe plus guard method. The four probe method requires four cables to be modified to connect to two probes at the probe end of the cables. Both methods require an 18 awg. or larger insulated wire for the guard connection. Keep cables at minimum length (1 meter) unless specified by individual equipment. Coaxial cables must be used to connect the probes to the meter. Meter accuracy ± 2%. The probe shields must be connected together. This connection should be short, approximately one to two inches.

2.2 Probe station with two coax probes and one regular probe. Recommendation: Micromanipulator, two (2) each coax probe model 44-FPC-6000 with #5 collet, and one each OON-FPC-6000 with #3 collet, or equivalent.

3 Procedure: Lead-to-Lead Capacitance(See Figure 1)

3.1 Set the instrument to measure at 1 Mhz. If the equipment has a cable length selection switch, adjust the switch to the appropriate coax cable length.

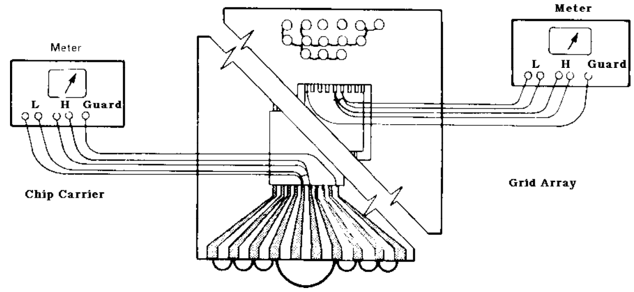

Figure 1
Lead-to-Lead Capacitance

3.2 Connect together all the pins in close proximity to those being measured, for multi-layer ceramic package pins should be chosen to connect all traces adjacent to traces being measured. Example: Eight surrounding pins are connected for the 68 lead pin grid; twelve surrounding pins are connected together for the 124 pin grid; eight surrounding pins are connected together for all flat packs (see Figure 1). If there are power planes and/or large power buses in the package, their pins must be connected together with the eight or 12 surrounding pins discussed above.

3.3 Place the guard probe down on the cavity side of any one of the eight or 12 leads discussed in Section 3.2, to ensure that they will not affect the measurement.

3.4 Place one coaxial probe approximately 1/8 inch above the cavity side of one of the leads to be measured.

3.5 Place the other coaxial probe approximately 1/8 inch above the cavity side of the other lead to be measured.

3.6 *Nulling Procedure* — If using an instrument that auto-zeros, such as the H.P.4275A, follow the instrument instructions for capacitance measurement. If this type of instrument is not being used, take the reading on the instrument at this point.

1 This test method applies to measurements in the range of 1 to 100 pico farands.

3.7 Place the probes down on the leads to be measured. This should be a vertical movement only.

3.8 Take the capacitance reading. If using auto-zeroing equipment, this capacitance measurement will be used. If not, take the reading from 3.6 and subtract it from the reading in 3.8 to derive the capacitance measurement of interest. (See Table 1.)

Table 1 Capacitance Nulling Procedurefor Non-Zeroing Equipment

Pins to be Measured	*Capacitance Reading at 3.6*	*Capacitance Reading at 3.8*	*Subtraction Step to Derive Desired Capacitance at 3.9*
1 & 2	C_1	C_2	$C_2–C_1 = C_3$
3 & 4	0.050 pf	2.130 pf	2.130–0.050 = 2.080 pf

For Auto-Zeroing Equipment:

Pins to be Measured	*Capacitance Reading at 3.6*	*Capacitance Reading at 3.8*	*Subtraction Step to Derive Desired Capacitance at 3.9*
5 & 6	C_1	C_2	$C_2–C_1 = C_3$
7 & 8	0.00 pf*	2.08 pf	2.080–0.000 = 2.080 pf

*Follow instrument instructions to read 0.00 pf

3.9 Repeat the procedure as required.

4 Procedure: Loading Capacitance (See Figure 2)

4.1 Omit guard terminal. Connect together all the pins in close proximity to the one to be measured. Example: Eight surrounding pins are connected together for the 68 pin grid; twelve surrounding pins are connected together for the 124 pin grid; eight surrounding pins are connected together for all flat packs (see Figure 2). If there are power planes and/or large power buses in the package, their pins must be connected together with the eight or 12 surrounding pins discussed above.

4.2 Place one coaxial probe approximately 1/8 inch above the cavity side of any one of the eight or 12 leads discussed in Section 4.1.

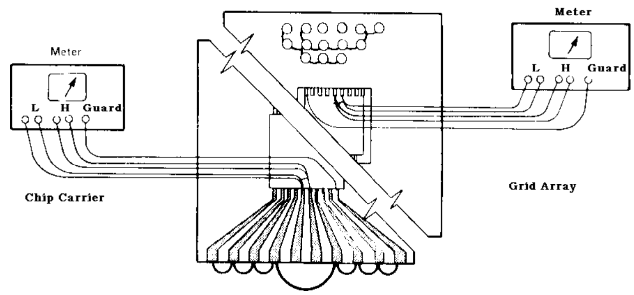

Figure 2
Loading Capacitance

4.3 Place the other coaxial probe approximately 1/8 inch above the cavity side of the lead to be measured.

4.4 Continue as in Steps 3.6 to 3.9.

4.5 Overall accuracy with this method is ± 5%.

SEMI G25-89
TEST METHOD FOR MEASURING THE RESISTANCE OF PACKAGE LEADS

1 Purpose

This document defines the equipment, materials, and procedure used to measure the resistance of leads in packaging elements. This document uses a pin grid (cavity down) package as one example of the type of packaging element that can be measured with the method described herein; however, this measurement technique can be applied to other geometrics with proper consideration.

2 Equipment and Materials

2.1 D.C. Ohmmeter which uses the four point probe (Kelvin) method with four cables. Minimum accuracy should be ± 4 mΩ.

2.2 Probe station with four probes. Probes should be such that the taper of the probe and the diameter of its point allow two probes to come together within a 5 mil. square without touching each other elsewhere. Recommendation: Micromanipulator, four each, probe number OON-FPC-6000 with #3 collet or equivalent.

3 Procedure

3.1 Place both probes of the low side of the meter as close together as possible on the shoulder or in the center of the outside lead (see Figure 1, Point A).

3.2 Place both probes of the high side of the meter within 5 mils of the end of the lead on the cavity side of the lead (see Figure 1, Point B).

3.3 Set the ohmmeter scale to the lowest setting possible without putting meter in an "over range" mode.

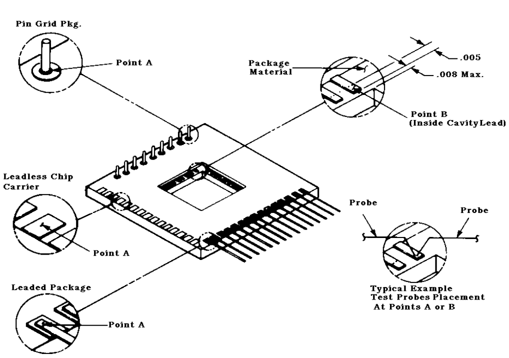

Figure 1
Resistance Measurement

3.4 Take resistance reading. Overall accuracy with this method is ± 20 mΩ. This accuracy estimate includes basic instrumentation error, probe placement repeatability, and typical package construction (printed pattern accuracy).

4 Application Note

Readings below 100 mΩ can be made with acceptable reeatability if considerable care in pleacement is taken. For example, in measuring a conductor made of tungsten 0.010" wide, a 0.010" variation in the distance between the two sets of probes will result in a 15 mΩ change in the measured reading. The same variation in a gold conductor would result in a 3–5 mΩ error.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI G26-90

SPECIFICATION FOR HERMETIC SLAM CHIP CARRIER LIDS

1 Preface

This specification covers the ceramic piece part commonly referred to as a lid, used in the construction of a hermetic SLAM package with a .050" pad centerline. The SLAM package is covered separately in the SEMI G5 Specification for Ceramic Chip Carriers.

2 Applicable Documents

MIL-STD-883[1] — Test Methods and Procedures for Microelectronics

MIL-M-38510 — General Specification for Microcircuits

MIL-I-23011 — Iron Nickel Alloys for Sealing to Glass and Ceramic

3 Selected Definitions

burr — A fragment of excess material or foreign particle adhering to the surface.

chip — Region of ceramic missing from the surface or edge of a package which does not go completely through the package. Chip size is given by its length, width and depth from a projection of the design plan-form (see Figure 1).

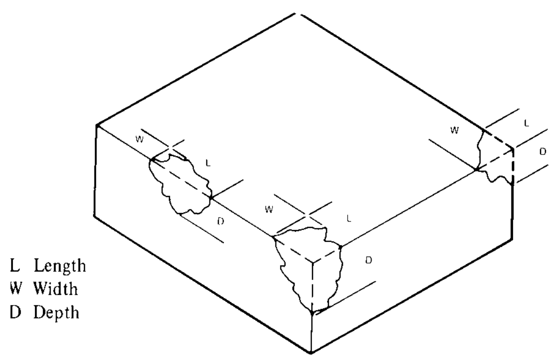

Figure 1
Chip Illustration

crack — A cleavage or fracture that extends to the surface of a package. It may or may not pass through the entire thickness of the package.

fin — A fine, feathery-edged projection on the edge or corner of the ceramic.

glass flow — Heated just sufficiently to remove all screen mesh marks visible at 10× magnification.

overhang — Horizontal extension of glass from the ceramic.

projection — Raised portion of the surface indigenous with the parent material.

pullback — Defines a dimension covering the linear distance between the edge of the ceramic and the first measurable glass interface excluding any glass spatter (see Figure 2).

rundown — Vertical extension of glass from the ceramic (see Figure 2).

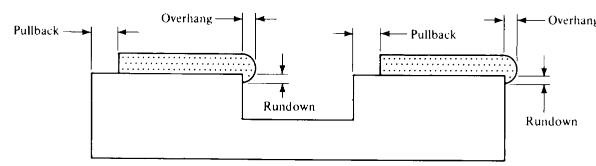

Figure 2
Glass Misalignment

seal area — A dimensional outline area designated for sealing the lid and package together.

terminal — Case outline at point of entry or exit of an electrical contact.

void —An absence of glass from a designated glassed area on the ceramic surface.

4 Ordering Information

Purchase orders for SLAM lids furnished to this specification shall include the following items:

1. Drawing number and revision level
2. Type and color of ceramic
3. Type and thickness of sealing material
4. Length, width, thickness and sealing area
5. Certification
6. Method of test and measurements (see Section 9)
7. Lot acceptance procedures (see Section 8)
8. Packaging and marking (see Section 10)

---

1 Military Standards, Naval Publications and Form Center, 5801 Tabor Ave., Philadelphia, PA 19120

5 Dimensions and Permissible Variations

The lid dimensions shall conform as specified in Figure 3 and Table 1.

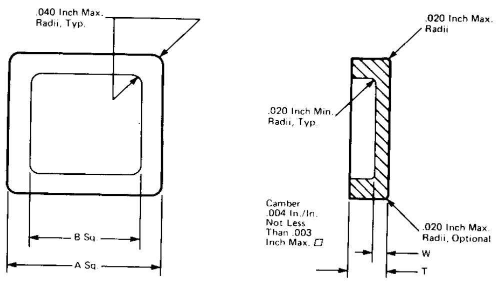

Figure 3
Dimensions

Table 1 Lid Dimensions for 0.050" Pad Centerline

Terminals	*Chip Carrier Base Thickness (Reference)*	*DIM A*	*DIM B*	*DIM T*	*DIM W*	*S/R, WIDTH*
20	0.020	0.310	0.230	0.060	0.020	0.040
28	0.025	0.410	0.330	0.060	0.025	0.040
44	0.040	0.500	0.420	0.065	0.025	0.040
68	0.040	0.700	0.560	0.065	0.022	0.070

6 Materials

6.1 Ceramic

6.1.1 Alumina content 90% minimum or Beryllia content 94% minimum.

6.1.2 Dark or white.

6.2 *Sealing Material* — As specified in the ordering information.

7 Defect Limits

7.1 *Ceramic*

7.1.1 *Cracks* — Cracks are not allowed.

7.1.2 *Chips*

7.1.2.1 *Corner* — 0.762 mm × 0.762 mm × 0.762 mm (0.030" × 0.030" × 0.030").

7.1.2.2 *Edge* — 0.762 mm × 0.762 mm × 0.762 mm (0.030" × 0.030" × 0.030").

7.1.2.3 Chips cannot reduce the seal path by more than 0.381 mm (0.015") or 10%, whichever is smaller.

7.1.3 *Burrs, Projections, and Fins* — Lids — 0.127 mm (0.005") maximum.

7.1.4 *Camber* — 0.004 inch/inch. For sizes below one inch the maximum camber shall be 0.076 mm (0.003").

7.2 *Glass*

7.2.1 *Chips or Voids* — There shall be no chips or voids after glass flow test.

7.2.2 Glass Misalignment — (As received.)

7.2.2.1 *External Overhang* — 0.254 mm (0.010") maximum.

7.2.2.2 *External Rundown* — 30% of ceramic thickness maximum at maximum material condition.

7.2.2.3 *Glass Pullback* — 0.254 mm (0.010") maximum.

7.2.2.4 Regardless of maximum allowable criteria stated above, the seal area must not be reduced by greater than 20% of the nominal design width.

7.2.3 Glass thickness shall be measured in four locations. Measurement shall be made on glass and base total thickness. Base reference thickness shall be measured on the same part by removal of a portion of the glass.

7.2.4 Glass splatter in all areas may not exceed 0.052 mm (0.002") in height, 0.127 mm (0.005") in diameter, with a maximum of three per 0.1" square area on the cavity surface.

8 Sampling

Sampling will be determined between supplier and purchaser.

9 Test Methods

9.1 *Sequence of Events and Functional Testing* — During functional testing, the sequence of testing shall be:

1. Seal
2. Vapor Content
3. Environmental Testing
4. Fine Leak
5. Gross Leak
6. Torque Test

9.2 *Hermetic and Environmental Testing*

9.2.1 The hermetic integrity of the package must be maintained after all environmental testing. Hermetic checks shall comply with MIL-STD-883, Method 1014, Test Conditions A_1, or B and C.

9.2.2 Environmental testing shall include: Temp Cycle, MIL-STD-883, Method 1010, Condition C.

10 Packaging and Marking

10.1 *Packaging* — Containers selected shall be strong enough and suitably designed to provide maximum protection against crushing, spillage and other forms of damage to the container or its contents. Containers shall afford protection of the contents to contamination from exposure to excessive moisture or oxidation by gases. Packaging materials shall be so selected to prevent any contamination of the ceramic component parts with paper fibers or organic particles.

10.2 *Marking* — The outer containers shall be clearly marked to identify the user stock number, user purchase order number, drawing number, quantity, vendor lot number, and solder glass type.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI G27-89
SPECIFICATION FOR LEADFRAMES FOR PLASTIC LEADED CHIP CARRIER (PLCC) PACKAGES

1 Preface

This specification is a guideline for high volume production of leadframes for plastic leaded chip carrier semiconductor packages. It is a design guideline for packaging engineers, leadframe stampers and mold manufacturers, and has been developed to meet the requirements of automatic assemblers.

2 Applicable Documents

2.1 *Order of Precedence* — To avoid conflicts, the order of precedence when ordering leadframes to this specification shall be as follows:

Purchase Order

This Specification

Referenced Documents

2.2 *SEMI Specifications*

SEMI G4 — Specification for Integrated Circuit Leadframe Material

SEMI G10 — Standard Method of Mechanical Measurement for Leadframes

SEMI G18 — Specification, Integrated Circuit Leadframe Materials Used in the Production of Etched Leadframes

SEMI G21 — Specification, Plating Integrated Circuit Leadframes

2.3 *Military and Federal Specifications*[1]

MIL-STD-105 — Sampling Procedures and Tables for Inspection by Attributes

MIL-STD-883 — Test Methods and Procedures for Microelectronics

2.4 *ANSI Specification*[2]

Y14.5M — Dimensioning and Tolerancing

2.5 *JEDEC Publication*[3]

Publication 9b — Registered and Standard Outlines for Semiconductor Devices

1 Military Standards, Naval Publications and Form Center, 5801 Tabor Avenue, Philadelphia, PA 19120

2 ANSI, 1430 Broadway, New York, NY 10018

3 JEDEC, 20001 Eye Street N.W., Washington, D.C. 20006

3 Selected Definitions

burr — a fragment of excess material either horizontal or vertical attached to the leadframe.

camber — curvature of the leadframe strip edge (see Figure 1).

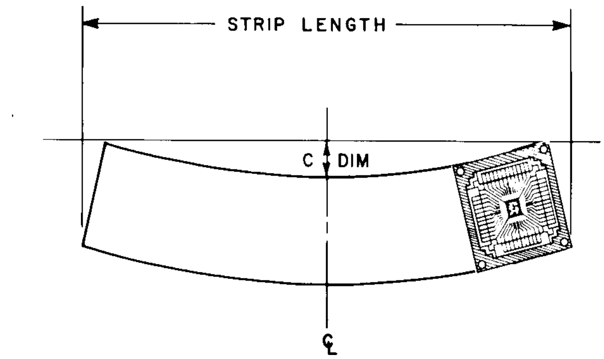

Figure 1
Camber

coil set — longitudinal bowing of the leadframe (see Figure 2).

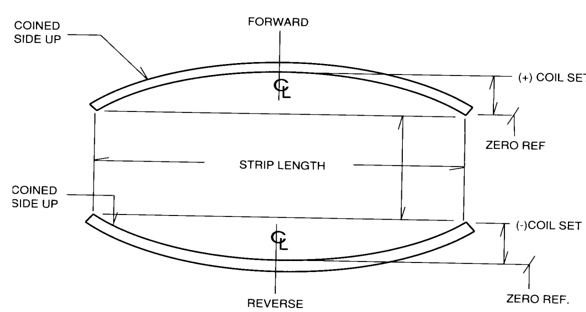

Figure 2
Coil Set

coined area — that area at the tip end of the bond fingers coined to produce a flattened area for functional use (see Figure 3).

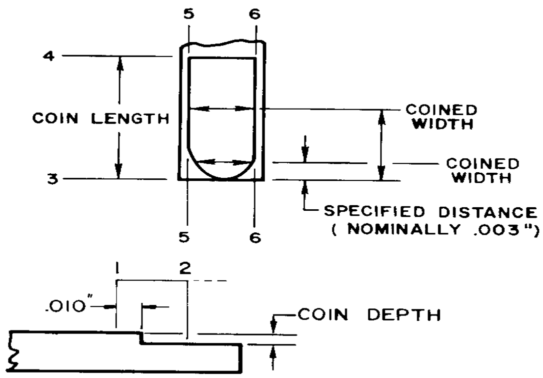

Figure 3
Coined Area

crossbow — transverse bowing of the leadframe (see Figure 4).

functional area — the die attach pad and the lead tips.

lead twist — angular rotation of bonding fingers (see Figure 5).

pits — shallow surface depression or craters in the leadframe material.

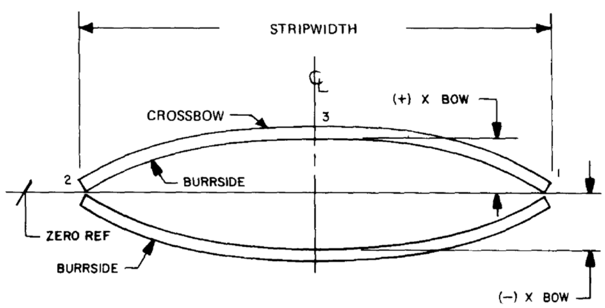

Figure 4
Crossbow

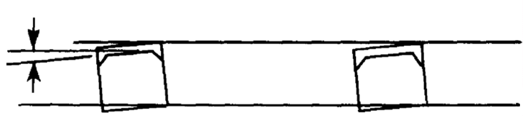

Figure 5
Lead Twist

slug marks — random dents in the leadframe caused by foreign material in the stamping die.

stamped leadframe terminology — (See Figure 6.)

true position circle — the circle with its center positioned at the center of the coined lead which defines the design position of the lead tip.

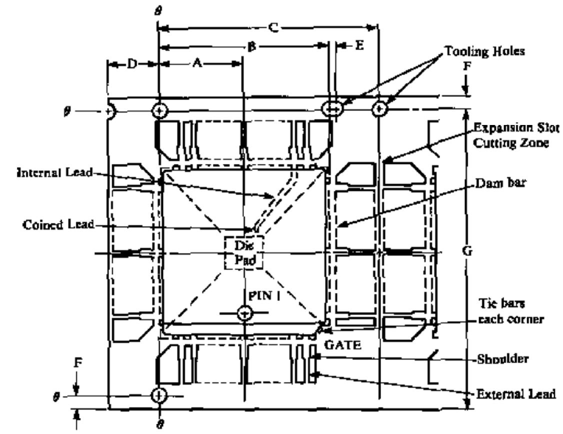

Figure 6
Plastic Leaded Chip Carrier Leadframe

4 Ordering Information

4.1 Purchase orders for leadframes furnished to this specification shall include the following information:

4.1.1 Current revision of the leadframe drawing detailing the base material and the plating type(s), thickness(es) and area(s).

4.1.2 Reference to this specification.

4.1.3 Vendor certification requirements.

5 Dimensions

See Table 1.

6 Defect Limits and Parameters

Note: Measurement methods are described in SEMI G10. Alternate methods may be used as agreed to between vendor and customer. The methods described in SEMI G10 are considered to be standard for the purpose of solving differences.

6.1 *Dimensional Tolerances* — See Figure 6.

6.2 *Minimum Flat Wire Bonding Area* — 80% of nominal lead width and 0.635 mm (0.025") in length.

6.3 *Coined Depth* — 0.013 mm (0.0005") min. to 30% of material thickness maximum.

6.4 *Horizontal Lead Spacing and Location (Lead Tips)*

6.4.1 The lead spacing and lead location that can be maintained is a function of the designed lead spacing and lead width.

Design Lead Width	*Design Lead Space*	*Minimum Lead Sapce*	*Minimum True Position Circle Dia.*
≥ 0.011"	≥ 0.011"	0.006"	0.007"
0.010"	0.010"	0.005"	0.006"

Tolerances for lead designs smaller than .010" should be negotiated between vendor and user.

6.4.2 *18 - 100 Pin Lead Frames* — Leads to be located so that a 0.007" diameter circle centered on the nominal center of the coined lead in width and 0.152 mm (0.006") back from lead tip in length shall be totally encompassed by the coined area.

Table 1 Plastic Leaded Chip Carrier Leadframe Standard Dimensions (all dimensions in inches)

Note 1: Gate — All packages; gate on the corner counter-clockwise from pin one.

Note 2: Dam Bar — Recommend 0.025 wide with 0.025 space between package and dam bar.

Note 3: Lead shall meet the JEDEC Quad Package requirements.

6.5 *Horizontal Die Attach Pad Location* — Die attach pad shall be located within 0.051 mm (± 0.002") on 18-100 pin leads.

6.6 *Lead Twist* — Shall not exceed 3° 30' or 0.015 mm (0.0006") per 0.254 mm (0.010") of lead width.

6.7 *Die Attach Pad Tilt and Flatness*

6.7.1 *Tilt* — 0.025 mm (0.001") maximum per 2.54 mm (0.100") of length or width in the undepressed state. 0.051 mm (0.002") maximum per 2.54 mm (0.100") of length or width in the depressed conditions when measuring from corner to corner.

6.7.2 *Flatness* — 0.005 mm (0.0002") per 0.100" pad length on 18-100 pin leadframes when measuring from the center to the average of the four corners. The corners are defined at 0.127 mm (0.005") from each edge.

6.8 *Die Attach Pad Downset or Depression* — The nominal downset recommended is 0.015" (0.381 mm) ± 0.002".

6.9 *Lead and Die Attach Pad Coplanarity*

6.9.1 *Lead Planarity* — The lead tips shall be within the following tolerances of the Z plane in the taped or untaped condition.

Table 2 Taped or Untaped Condition

No. of Leads	*Strip Width*	*Lead Tip Coplanarity*
18 Rect.	1.070" - 1.230" (27.18 mm - 31.24 mm)	± 0.003" (0.76 mm)
20 Square	0.970" (24.64 mm)	± 0.003" (0.076 mm)
28-52	1.070" - 1.470" (27.18 mm - 37.34 mm)	± 0.004" (0.120 mm)
64-84	1.670" - 1.870" (42.42 mm - 47.50 mm)	± 0.005" (0.127 mm)

6.9.2 *Die Attach Pad Planarity* — The die attach pad shall be within the following tolerances of the Z plane.

6.10 *Material*

6.10.1 0.203 mm (0.008") material thickness recommended for greater than 52 leads.

6.10.2 0.254 mm (0.010") material thickness recommended for 52 lead and below.

6.10.3 Nominal thickness tolerances for both Alloy 42 and copper materials of 0.203 mm (0.008") and 0.254 mm (0.010") shall be 0.008 mm (± 0.0003").

6.10.4 *Width Tolerance* — 0.051 mm (± 0.002") for both Alloy 42 and copper.

6.11 *Coil Set* — Maximum of 0.508 mm (0.020") over the nominal strip length. Does not include material thickness.

6.12 *Crossbow* — Crossbow shall not exceed the following dimensions:

No. of Leads	*Maximum Crossbow*
18—20	± 0.005" (0.127 mm)
28 - 52	± 0.006" (0.152 mm)
68 - 84	± 0.010" (0.254 mm)

6.13 *Camber* — Shall not exceed 0.002" over nominal strip lengths of 8 ± 2 inches.

The relationship to determine maximum camber for other lengths is approximated as follows:

$$\frac{C_1}{C_2} = \frac{L_1^2}{L_2^2}$$

6.14 *Progression* — The progression over the nominal strip length shall be within 0.051 mm (± 0.002") and noncumulative.

6.15 *Burrs* — Shall be firmly attached and able to withstand a probe force of 10 grams. Vertical burrs inside the dambar shall not exceed 0.025 mm (0.001"). Vertical burrs outside the dambar and horizontal burrs in any location shall not exceed 0.051 mm (0.002").

6.16 *Pits and Slugmarks*

6.16.1 Within functional area and on external leads, there shall be no slugmarks. Pits shall not exceed 0.008 mm (0.0003") in depth and 0.013 mm (0.0005") in largest surface dimension in these areas.

APPLICATION NOTE: There is a question regarding the ability of material suppliers to meet this specification. Revision of this specification is under review.

6.16.2 In other areas, pits and imperfections shall not affect leadframe strength regardless of size and shall not exceed 0.051 mm (0.002") in depth and 0.127 mm (0.005") in largest surface dimension.

6.17 *Strip Cut Off Location* — Strip cut off shall be within 0.076 mm (± 0.003") of basic strip length (see Figure 6).

6.18 *Coining and Metal Clearance*

6.18.1 Dimensions shown on drawings are before coin dimensions.

6.18.2 Maximum coining bulge shall not exceed 0.051 mm (0.002") per edge and shall be governed by metal to metal clearance requirements (lead to lead and lead to pad).

6.18.3 *Metal to Metal Clearance* — Shall be as agreed to between vendor and customer.

7 Sampling

7.1 The sampling plan shall be agreed upon between vendor and customer.

8 Packaging and Marking

8.1 *Packaging* — Containers and packaging materials shall be selected to provide protection against normal transportation damage risks and spillage. They will also offer protection from contamination, exposure to moisture, oxidation, and tarnishing.

8.2 *Marking*

8.2.1 The following details shall be noted on the packing slip attached to the outside of the shipping package:

Vendor Part Number

Customer Part Number

Quantity

Date

Vendor Lot Number

User PO Number

Drawing Number

SEMI G28-0997
SPECIFICATION FOR LEADFRAMES FOR PLASTIC MOLDED S.O. PACKAGES

1 Purpose

This specification defines the acceptance criteria for stamped leadframes for plastic molded S.O. packages.

2 Scope

This specification is a guideline for production of stamped S.O. Leadframes to be used in plastic molded S.O. packages.

3 Referenced Documents

3.1 *SEMI Specifications*

SEMI G4 — Specification for Integrated Circuit Leadframe Materials used in the Production of Stamped Leadframes

SEMI G9 — Specification for Stamped Leadframes for Plastic Molded Dual-In-Line Semiconductor Packages

SEMI G10 — Standard Method for Mechanical Measurement for Plastic Package Leadframes

SEMI G21 — Specification for Plating Integrated Circuit Leadframes

3.2 *ANSI/ASQC Specifications*[1]

ANSI/ASQC Z1.4 — Sampling Procedures and Tables for Inspection by Attributes

3.3 *ANSI Specifications*[2]

ANSI Y14.5M — Dimensioning and Tolerancing

4 Terminology

4.1 *burr* — A fragment of excess material either horizontal or vertical adhering to the component surface.

4.2 *camber* — Curvature of the leadframe strip edge in the horizontal plane (see Figure 1).

4.3 *coil set* — Longitudinal bowing of the leadframe (see Figure 2).

4.4 *coined area* — That area at the tip of the bond fingers flattened to produce an acceptable surface for wire bonding (see Figure 3).

4.5 *crossbow* — Transverse bowing of the leadframe (see Figure 4).

4.6 *functional area* — The die attach pad and the wire bond (lead tips) area.

4.7 *lead twist* — Angular rotation of bonding fingers (see Figure 5).

4.8 *pit* — A shallow surface depression or crater in the leadframe material.

4.9 *slugmarks* — Random dents in the leadframe caused by foreign material in the stamping die.

4.10 *stamped leadframe terminology* — (See Figure 6.)

5 Ordering Information

Purchase orders for leadframes for plastic molded S.O. packages furnished to this specification shall include the following items:

a. Current leadframe specification drawing.

b. All dimensions and tolerances per ANSI Y14.5 practices.

c. Material type and physical characteristics (see SEMI G4).

d. Type hardness and thickness of any required plating (see SEMI G21).

6 Dimensions

See Table 1 and Figure 7 for standard dimensions. Tolerances shall be agreed between vendor and customer.

7 Defect Limits and Parameters (see SEMI G10 for measurement methods)

7.1 *Internal Frame Area*

7.1.1 *Minimum Flat Wire Bonding Area* — 80% of nominal lead width and .015" (.381 mm) in length.

7.1.2 *Coin Depth*

7.1.2.1 0.008" (0.20 mm) material: 0.0005" (0.013 mm) minimum/0.001" (0.02 mm) maximum.

7.1.2.2 0.010" (0.25 mm) material: 0.0005" (0.013 mm) minimum/0.002" (0.05 mm) maximum.

1 ASQC, 611 East Wisconsin Avenue, Milwaukee, WI 53202

2 ANSI, 1430 Broadway, New York, NY 10018

NOTE: Maximum coin depth may also be constrained by minimum lead spacing requirement given in Section 7.1.3.1. Minimum coin depth may also be constrained by minimum bond area requirement given in Section 7.1.1.

7.1.3 *X-Y Plane Lead Spacing and Location*

7.1.3.1 Spacing between leads to be 0.004" (0.100 mm) minimum.

7.1.3.2 Leads to be located so that a 0.007" diameter circle centered on the nominal center of the coined lead in width and 0.006" (0.152 mm) back from lead tip in length shall be totally encompassed by the coined area.

7.1.4 *X-Y Plane Die Attach Pad Location* — Die attach pad to be located within ± 0.002" (0.051 mm) as measured from the centerline of the reference hole in the side rail.

7.1.5 *Lead Twist* — Shall not exceed 3°30’ or 0.0006" (0.015 mm) per 0.010" (0.254 mm) of lead width.

7.1.6 *Die Attach Pad Tilt and Flatness*

7.1.6.1 *Tilt* — 0.001" (0.025 mm) maximum per 0.100" (2.54 mm) in the undepressed state. 0.002" (0.015 mm) maximum per 0.100" (2.54 mm) in the depressed condition.

7.1.6.2 *Flatness* — To be within 0.002" (0.051 mm) T.I.R. per 0.100" (2.54 mm) when measured from the center to each of the four corners. The corners are defined at 0.005" (0.127 mm) from each edge.

7.1.7 *Die Attach Pad Downset* — ± 0.002" (0.051 mm) as measured from the center of the pad to a point on the bar pad support strip. The nominal downset recommended is 0.012" (0.30 mm) for 0.010" (0.25 mm) thick material and 0.008" (0.20 mm) for 0.008" (0.20 mm) thick material.

7.1.8 *Lead and Die Attach Pad Coplanarity*

7.1.8.1 The coplanarity relationship is based on reference to the Z plane (see SEMI G10).

7.1.8.2 *Lead Planarity* — The lead tips as measured in the center of the back, uncoined surface of the lead tip shall be located within the following tolerances of the Z plane:

Lead Planarity: ± 0.004"

7.1.8.3 *Die Attach Pad Planarity* — The die attach pad when measured at the center must be within the following tolerances of the Z plane:

Pad Planarity: + 0.003"/-0.005"

7.2 *External Area and Strip*

7.2.1 *Material*

7.2.1.1 0.008" (0.20 mm) material thickness recommended for 0.150" wide packages.

7.2.1.2 0.010" (0.25 mm) material thickness recommended for 0.300" wide packages.

7.2.1.3 *Nominal Thickness* — Tolerances shall be ± 0.0003" (0.008 mm).

7.2.1.4 *Width Tolerance* — ± 0.002" (0.051 mm).

7.2.2 *Coil Set* — Maximum of 0.125" (3.175 mm) measured in a free standing state over strip length.

7.2.3 *Crossbow* — Crossbow shall not exceed the following dimensions:

Maximum Crossbow: ± 0.005" (0.127 mm)

7.2.4 *Camber* — Shall not exceed 0.002" (0.05 mm) over a gage length of 6.00" (150 mm). (See SEMI G10.)

7.2.5 *Progression* — Should be specified along with tolerances on the drawing.

7.2.6 *Burrs* — Burrs shall be firmly attached and able to withstand a probe force of 10 grams. Vertical burrs inside the dambar shall not exceed 0.001" (0.02 mm). Vertical burrs outside the dambar and horizontal burrs in any location shall not exceed 0.002" (0.05 mm).

7.2.7 *Pits and Slugmarks*

7.2.7.1 Within functional area and on external leads there shall be no slugmarks. Pits shall not exceed 0.0003" (0.008 mm) in depth and 0.0005" (0.013 mm) in largest surface dimension in these areas.

7.2.7.2 *Areas Other than 7.2.7.1* — Pits and imperfections shall not affect leadframe strength regardless of size and shall not exceed 0.002" (0.05 mm) in depth and 0.005" (0.127 mm) in largest surface dimension.

7.2.8 *Strip Length Cutoff* — (See SEMI G10.)

7.2.8.1 Strip cutoff location and tolerance shall be detailed on the drawing.

7.2.8.2 Overall strip length and tolerance shall be detailed on the drawing.

8 Functional Testing

Functional testing shall be agreed upon between vendor and customer.

9 Sampling

Sampling based on ANSI/ASQC Z1.4 shall be agreed between supplier and purchaser.

10 Packaging, Marking, and Packing List

10.1 *Packaging* — The shipping containers and materials shall be suitably designed to provide the leadframes with protection against normal transportation damage risks which include crushing and spillage, and exposure to moisture and other corrosive gases.

10.1.1 The inner packaging materials for cut strips must not cause particulate contamination on the leadframes and shall be clean room compatible as defined by the customer. The leadframes boxes shall be vacuum sealed in a bag with a desiccant. If the leadframes are to be delivered in coil form, the coil diameter shall be set in the purchase order (see SEMI G9).

10.2 *Marking*

10.2.1 *Internal Packages* — Each internal package shall be clearly marked with the following information, as appropriate:

a. Customer's part number

b. Customer's purchase order number

c. Drawing number (customer's and/or vendor's, as requested by customer)

d. Vendor's shipping lot number

e. Quantity

f. Date of Manufacture

g. Any agreed upon certification data

10.2.2 *External Packages* — The packing list on the outside of the external package shall contain the following information:

a. Customer's part number

b. Customer's purchase order number

c. Quantity

d. Shipping Date

e. Any specific instructions for receiving dock personnel

11 Certification

11.1 Upon request of the customer in the contract or purchase order, a vendor's certification that the product was manufactured and tested in accordance with this specification, together with a report of the test results shall be furnished at the time of shipment. However, if the customer does perform inspection and test on a certified shipment and the product fails to meet the requirements, the product shall be subject to rejection.

11.2 If the customer and vendor agree, the product may be certified as capable of meeting this specification. In this context, capable of meeting signifies that the vendor is not required to perform all the inspections and tests. However, if the customer does perform inspection and test on a certified shipment and the product fails to meet the requirements, the product shall be subject to rejection.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer’s instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user’s attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI G29-1296
TEST METHOD FOR TRACE CONTAMINANTS IN MOLDING COMPOUNDS

1 Purpose

This specification defines the test method for determination of extractable trace contaminants in molding compound.

2 Scope

This test method is suitable for all molding compound materials and may be used by supplier and customers to determine the trace contaminants in molding compound.

3 Referenced Documents

3.1 *ASTM Documents*[1]

ASTM D 1193 — Specification for Reagent Water

ASTM D 4327 — Anions in Water by Ion Chromatography

4 Method Summary

Plastic molding compound material is molded, ground to a defined mesh size, and placed into a sealed extraction vessel with de-ionized water. Extraction is carried out at 120 ± 2°C for 48 hours. The extract is analyzed for both anionic and cationic impurities.

5 Sample Preparation

5.1 Samples of molding compound materials may be obtained from either standard molding operations, or prepared in the laboratory.

5.1.1 Samples from molding operations may include mold runners post-cured according to manufacturer's recommendations.

5.1.2 To secure a sample in the laboratory, spread a thin layer of uncured compound in a dedicated clean teflon-coated container. Cure and post-cure the compound material according to manufacturer's recommendations.

5.2 Crush the cured material using a suitable grinding apparatus, such as Spex mixer-mill No. 8000, or equivalent.

NOTE 1: The grinder used must not generate excess localized heat, or else sample decomposition and erroneous results may be generated.

NOTE 2: Addition of liquid nitrogen is a suitable method for eliminating undesirable thermal decomposition during grinding.

5.3 Remove the ground compound and sieve it. Collect for analysis the portion which passes through a 40 mesh size, but is retained on a 100 mesh size screen. This particle size is best suited for adequate extraction of impurities.

5.4 Weigh 10% 0.1 grams of the powdered material and place in an extraction vessel. Parr bombs with teflon liners are suitable extraction vessels. Add 100 ml de-ionized water. Prepare blank extraction vessel by processing it in the same manner as your sample. Weigh the sealed bombs and record their weights. Place the sealed bottles on their sides in an oven at 120 ± 2°C for forty-eight (48) hours.

NOTE 3: Certain compounds may require addition of reagent grade methanol 10% (V:V) to enhance wetting.

5.5 At the completion of forty-eight (48) hours of extraction, allow the bombs to cool to room temperature and reweigh. If the weight loss exceeds 0.5 grams the sample should not be used for analysis. Portion of this extract may be used to generate pH and conductivity data. Anion analysis may be performed using ion chromatography or specific ion electrodes. Cation analysis may be conducted using atomic absorption, plasma spectrometry, or ion chromatography.

NOTE 4: It is important to avoid contamination with particulate matter in the extract used for the analysis by AA, ICAP, or IC. This procedure addresses determination of extractive species only.

6 Instrumentation Techniques

6.1 *Measurement of Conductivity*

6.1.1 *Apparatus* — Conductivity Meter Model RC1682 with microconductivity cell, industrial instruments, or equivalent.

6.1.2 *Measurement* — Measure conductivity of the sample and black solutions. Calculate the specific conductance of sample using the following equation:

$L_s = (L_e - L_b) K$

L_s - Specific conductance, S cm^{-1}

L_e - Conductance of extract, S

L_b - Conductance of the blank

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohoken, PA 19428-2959

K - Conductivity cell constant

6.2 *Measurement of pH*

6.2.1 *Apparatus*

6.2.1.1 pH meter (Orion, Model 601, or equivalent)

6.2.1.2 pH standard solutions

6.2.2 *Measurement* — Adjust pH meter indicator by using standard solutions. Remove the electrodes with de-ionized water and dry with clean filter paper. Place the electrodes into the molding compound extract. Allow the meter to equilibrate. Record the pH value.

6.3 *Ion Specific Electrodes* — Ion-specific electrodes may be used for the determination of chloride, bromide, sulfate, and phosphate. A separate specific electrode for each ion is required and, in some instances, a reference electrode may be necessary to complete the test. Individual standards are needed for each ion tested. Methodology recommended by the manufacturer for each ion specific electrode should be closely followed. Measured concentrations corrected for blank value should be compared to the known standards in the range 0.1–100 ppm. Chloride and bromide are usually determined, using a solid state single electrode. Determination of sulfate and phosphate ions may require use of additional buffers and a titration.

6.4 *Determination of Sodium, Potassium, and Antimony Using Atomic Absorption*

6.4.1 *Apparatus* — Atomic absorption spectrophotometer.

6.4.2 *Standard Solutions*

6.4.2.1 Sodium standard solutions 0.1, 0.2, 0.4, 0.6, 0.8, 1.0 ppm.

6.4.2.2 Potassium standard solutions 0.1, 0.2, 0.4, 0.6, 0.8, 1.0 ppm.

6.4.2.3 Antimony standard solution 0.1, 0.2, 0.4, 0.6, 0.8, 1.0 ppm.

6.4.3 *Measurement* — Set up instrument according to manufacturer's recommendation. Analyze water extract based on the calibration curve prepared using standard solutions to obtain concentration of ion of interest.

6.4.4 *Calculation*

6.5 Determination of Chloride, Bromide, Phosphate, Sulfate, Sodium, and Potassium by Ion Chromatography

6.5.1 *Method Principle* — Ion chromatography is a form of liquid chromatography used in the separation and quantitation of ions. A filtered aliquot of sample is injected into an Ion chromatograph. The sample is pumped by the eluent stream through two (2) different ion exchange columns: a guard column, which serves to protect the separator column from residual particulate matter and retain certain organics, and the separator column, the primary function of which is to separate analyzed ions based on their affinity for the exchange sites of the resin. Both guard column and the separator column are packed with identical low capacity anion exchanger (anion analysis) or cation exchange (cation analysis). The separated ionic species then pass to a detector module consisting of a chemical suppressor device and a conductivity cell. The suppressor device is used to reduce background conductivity of the eluent to a low, or negligible level, and convert analyte anions into their acid form or analyte cations into their hydroxide form. Thus, separated and modified ionic species are detected using an electrical conductivity cell. Anions are identified based on their retention time compared to the known standards. Quantitation is accomplished by measuring the peak height or area, and comparing it to a calibration curve generated from known standards.

NOTE 5: For recommended practice for ion chromatography analyses, see instrument manufacturer's literature and ASTM D 4327.

6.5.2 *Interferences*

6.5.2.1 High levels of organic acids may be present in molding compound extracts. This may interfere with inorganic anion analysis. Two (2) common species, formate and acetate, elute between fluoride and chloride. This may be minimized by modifying instrument set-up.

6.5.2.2 Certain amines may interfere with the determination of sodium or potassium. This may be minimized by using different instrument set-ups.

6.5.3 *Apparatus*

6.5.3.1 Ion chromatograph (Dionex or equivalent). The chromatograph shall be equipped with an injection valve, a 50–100 µl sample loop, and shall be set up with the following:

1. Guard Column
2. Separator Column
3. Chemical Suppressor Device
4. Conductivity Detector

6.5.4 *Reagents*

6.5.4.1 *Water Purity* — Water used in the preparation of eluents, standards, and sample extraction shall conform to ASTM D 1193.

6.5.4.2 *Reagent Purity* — Reagent grade chemicals should be used in all tests.

6.5.4.3 *Eluent/Regenerant Solutions* — Should be prepared in accordance with instrument manufacturer's instructions recommended for each column set.

6.5.4.4 *Stock Solutions* — Stock solutions (1 ml - 1 mg - 1 ppm ion of interest) should be prepared according to accepted practice, and as described in the instrument manufacturer's instructions.

6.5.4.5 *Calibration Standards* — Prepare a blank and at least three (3) different calibration solutions containing combination of anion/cations. These solutions must be prepared in volumeric flasks (see Table 1).

6.5.4.5.1 Prepare a standard solution I by diluting the volume of each anion/cation stock solution as specified in Table 1 together with 1 litre of water.

6.5.4.5.2 Prepare a standard solution II by diluting 20 ml of standard solution II to 100 ml with water (see Table 1).

NOTE 6: If the concentrations of the sample ions are known, or estimated, the concentration of calibration standard solutions may be varied to better approximate or bracket concentration range of interest.

6.5.5 *Calibration*

6.5.5.1 Analyze the blank and each of the prepared calibration solutions described in Section 6.5.4.5.

6.5.5.2 Prepare analytical curves for each anion/cation of interest by plotting on linear graph paper peak height or peak area versus nominal concentrations of the anion/cation calibration standard.

NOTE 7: Each analytical curve should be established using only one (1) scale setting.

6.5.6 *Procedure*

6.5.6.1 Set-up the ion chromatograph according to the manufacturer's instructions.

NOTE 8: The range setting required for the analysis will depend on the concentration of ions in the sample and should be chosen accordingly. For these types of samples, operating range from 30 to 30µ S/cm, full scale is most frqurntly used.

6.5.6.2 Equilibriate the system by pumping eluent through the analytical system until a stable baseline is obtained (approximately twenty (20) minutes).

6.5.6.3 Filter samples through a pre-washed 0.22 µm filter prior to analysis.

NOTE 9: Several types of syringe-tip filters are available (Millipore or equivalent).

6.5.6.4 Load 2–3 ml of sample into the injection part using a syringe. Inject the sample into the eluent stream and record the ion chromatogram.

6.5.7 *Calculations*

6.5.7.1 Refer to the peak height or area for the anions/cations of interest to the appropriate analytical curves to determine the anion concentration.

6.6 *Inductivity Coupled Argon Plasma Spectrometry/ICP*

6.6.1 *Method Principle* — Inductivity coupled Argon Plasma (ICP) uses high frequency Argon Plasma to excite sample constituents to 8000°K. Because the plasma ionizes most atomic species, background interferences are vastly reduced and linear response over several orders of magnitude can be observed for most elements. The sample extract is aspirated into the plasma by means of a high purity argon carrier gas. The resulting emissions are directed into the spectrometer and signal strengths are read by photomultiplier tubes placed at emission points in a focal curve. A computer is used to scan each elemental channel many times a second, and this output is sent to a printer in numerical form. The cycle or time of analysis is usually about seven (7) seconds. With this instrument, very little of the extracted sample is consumed.

6.6.2 *Instrument Conditions*

Typical operating conditions are:

Excitation source	27 MHz plasma
Carrier gas	99.999% Argon
Sample flow	1 ml/min
Power output	1000 watts
Plasma temperature	8000°K
Slit width of Spectrometer	30 µm

6.6.3 *Measurement of Sodium, Potassium, and Antimony* — A standard solution of ten (10) ppm of sodium, potassium, and antimony should be prepared and cycled through the ICP instrument. The blank extract sample and the unknown molding compound extracts are then run through the ICP. The values obtained for sample are corrected by subtracting values obtained for the blank. With the ICP, sodium, potassium, and antimony can be analyzed with sensitivities to the ten (10) PPB levels. Any additional elements present may be obtained on the same cycle with no additional preparation.

Table 1 Preparation of Standard Solutions for Instrument Calibration

Anion	*Standard Solution*		*Standard Solution II*	*Standard Solution III*
	ml of Stock Soln. Diluted to 1000 ml	*Anion Conc. mg/1*		
Chloride (Cl)	5	5	1	0.2
Phosphate (HPO_4^{2-})	25	25	5	1.0
Bromide (Br^-)	10	10	2	0.4
Nitrate (NO_3	30	30	6	1.2
Sulfate (SO_4^{2-})	25	25	5	1.0
Cation

Potassium (K^+)	10	10	2	0.4

SEMI G30-88
TEST METHOD FOR JUNCTION-TO-CASE THERMAL RESISTANCE MEASUREMENTS OF CERAMIC PACKAGES

1 Purpose

The purpose of this test is to determine the thermal resistance of ceramic packages using thermal test chips. This test method deals only with junction-to-case or mounting surface measurements of thermal resistance and limits itself to heat sink and fluid bath testing environments. Following the guidelines outlined in this test method, junction-to-case thermal resistance measurements of ceramic packages using the heat sink and fluid bath methods should give the same results only under certain limited conditions (i.e., under conditions that approximate unidirectional heat flow through the chip and substrate to the preferred heat removal surface). If discrepancies occur, the heat sink mounting technique shall be considered as the referee test method. The heat sink mounting method for measuring junction-to-case thermal resistance will be a conservative measure of the package's ability to transfer heat to the ambient environment because heat sinking is provided only on one side of the package, whereas the fluid bath mounting method has the potential for equally cooling both sides of the package.

1.1 *Definitions* — The following definitions and symbols shall apply for the purpose of this test:

a. *case temperature,* T_C, in degrees Celsius. The case temperature is the temperature at a specified accessible reference point on the package in which the microelectronic chip is mounted.

b. *mounting surface temperature,* T_M, in degrees Celsius. The mounting surface temperature is the temperature of a specified point at the device-heat sink mounting interface (or primary heat removal surface).

c. *junction temperature,* T_J, in degrees Celsius. The term is used to denote the temperature of the semiconductor junction in the microcircuit in which the major part of the heat is generated. For purposes of this test, the measured junction temperature is only indicative of the temperature in the immediate vicinity of the element used to sense the temperature.

d. *power dissipation,* P_H, in watts, is the heating power applied to the device causing a junction-to-reference point temperature difference.

e. *thermal resistance, junction-to-specified reference point,* $R_{\Theta JR}$, in degrees Celsius/watt. The thermal resistance of the microcircuit is the temperature difference from the junction to some reference point on the package divided by the power dissipation P_H.

f. *temperature-sensitive parameter,* TSP, is the temperature-dependent electrical characteristic of the junction under test which can be calibrated with respect to temperature and subsequently used to detect the junction temperature of interest.

2 Apparatus

2.1 The apparatus required for these tests shall include the following as applicable to the specified test procedures.

a. Thermocouple material shall be copper-constantan (type T) or equivalent, for the temperature range -100 to +300°C. The wire size shall be no larger than AWG size 30. The junction of the thermocouple shall be welded to form a bead rather than soldered or twisted. The accuracy of the thermocouple and associated measuring system shall be ± 0.5°C.

b. Suitable electrical equipment as required to provide controlled levels of conditioning power and to make the specified measurements. The instrument used to electrically measure the temperature-sensitive parameter shall be capable of resolving a voltage change of 0.5 mV.

c. Controlled temperature chamber, fluid bath, or heat sink capable of maintaining the specified reference point temperature to within ± 0.5°C of the preset (measured) value. Typical temperature-controlled heat sink and fluid bath assemblies are presented for illustrative purposes only.

2.2 *Heat Sink Assembly* — A typical heat sink assembly for mounting the microelectronic device under test is shown in Figure 1. The primary heat sink is water cooled using a temperature-controlled fluid circulator bath. An adapter socket/heat sink is fastened to the heat removal surface of the primary heat sink, and has a special geometry to handle specific size packages (e.g., flat packs, dual-in-line packages, chip carriers). This adapter provides a repeatable and efficient interface between the package and the primary heat sink. The mounting surface temperature is determined with a thermocouple attached from the side or bottom of the adapter with a thermal conducting adhesive or grease at or near the interface between the adapter and the package. It is at this point that the device-under-test temperature is specified and controlled. The adapter also contains the socket or other electrical interconnection scheme. A thin coating (about 25 – 50 mm thick) of a thermal heat-sinking compound, such as zinc-oxide-loaded silicone thermal grease, is used at the interface to provide a reliable thermal contact.

2.3 *Fluid Bath Assembly* — A typical temperature-controlled fluid bath for thermally characterizing the microelectronic device under test is shown in Figure 2. In this figure, the package is mounted in a fluid bath separate from the fluid circulator, although it can be immersed directly in an integrated fluid circulator/bath unit. The fluid in the bath should be continuously stirred or agitated to ensure the required temperature stability. Since this working fluid is being used as an infinite heat sink, the case-to-fluid (ambient) temperature difference at the case temperature reference point of interest should be minimized, i.e., less than or equal to 20°C. For case-to-fluid temperature differences greater than 20°C, accuracy and repeatability difficulties may occur due to a large variable temperature gradient in the fluid film boundary layer at the package-fluid interface. The case-to-fluid temperature difference can be minimized by increasing the fluid velocity and by decreasing the power density seen by the fluid. The device under test should be mounted such that heat transfer to the fluid is not impeded. For leaded devices, the leads should be oriented in such a manner so as not to interfere with the heat transfer to the fluid and provide freedom to any thermal currents caused by the power dissipation within the package. The case temperature of the device under test should be measured with a thermocouple that is attached to the package and should not be assumed to be at the fluid temperature. Care should be taken to minimize exposure of the thermocouple bead to the high temperature gradient in the fluid film boundary layer at the package-fluid interface. The working fluid should have a thermal conductivity at 25°C of at least 0.0006 W/cm°C. Working fluids such as inert fluorocarbon liquids and silicone oils are suitable as a cooling media.

3 Procedure

3.1 *Direct Measurement of Reference Point Temperature* — T_C. For the purpose of measuring a microelectronic device thermal resistance, the reference point temperature shall be measured at the package location of highest temperature which is accessible outside the package. This reference point location is determined with the device operating in free air and with no external heat-sinking. In general, this reference point is found to be on the outside surface of the package substrate directly underneath the chip in the major path of heat flow from the chip to the heat sink or ambient. Examples of the reference point location for both cavity-up and cavity-down ceramic packages are depicted in Figure 3. The package surface may be altered to facilitate this measurement, provided that such alteration does not affect the original heat transfer paths and, hence, the thermal resistance, within the package by more than a few percent. For packages with an integral heat dissipater attached to the outside surface of the package substrate, the case temperature reference point shall be on the surface of the heat dissipater at a point opposite the backside of the chip as indicated in Figure 4.

3.1.1 Case temperature, T_C. The microelectronic device under test shall be mounted under specified conditions so that the case temperature can be held at the specified value. A thermocouple shall be attached on the surface of the device package directly under the chip. A conducting epoxy may be used for this purpose. The thermocouple bead should be in direct mechanical contact with the case of the microelectronic device under test. For devices which, in their normal application, are intimately connected (by pressure contact, adhesive, soldering, or other means) to an external heat sink, the mounting surface temperature, as measured directly below the primary heat removal surface of the case, may be used as the equivalent case temperature.

If it is found that attaching the thermocouple directly to the case is impractical, an alternate approach utilizing a thermocouple welded to one side of a thin metal disk should be used. This can be accomplished by parallel gap welding the crossed thermocouple wires to one side of a 0.25 cm (0.094 in) diameter, 0.02 cm (0.008 in) thick beryllium-copper disk and then, with a thin layer of adhesive, bonding the other side of the disk to the case at the point of interest.

3.1.1.1 Mounting surface temperature, T_M. The mounting surface temperature is measured directly below the primary heat removal surface of the case. It is measured with a thermocouple at or near the mounting surface of the heat sink. A typical mounting arrangement is shown in Figure 5. The surface of the copper mounting base shall be nickel plated and free of oxides.

The thermocouple hole shall be drilled into the mounting base such that the thermocouple lead is directly below the area on the case of interest. It is recommended that the thermocouple be secured into the mounting base with a thermal conducting adhesive (or solder) and that particular attention be paid to minimizing air voids around the ball or the thermocouple. A thermal conducting compound (or adhesive) should be used at the interfaces of the mounting base and the device under test. The mounting surface technique is application oriented in that it takes into account the mounting surface interface.

3.2 *Thermal Resistance, Junction-to-Specified Reference point,* $R_{\Theta JR}$

3.2.1 *General Considerations* — The thermal resistance of a semiconductor device is a measure of the ability of its carrier or package and mounting technique to provide for heat removal from the semiconductor junction. The thermal resistance of a microelectronic device can be calculated when the case/mounting surface temperature and power dissipation in the device and a measurement of the junction temperature are known.

When making the indicated measurements, the package shall be considered to have achieved thermal equilibrium when halving the time between the application of power and the taking of the reading causes no error in the indicated results within the required accuracy of measurement.

3.2.2 *Indirect Measurement of Junction Temperature for the Determination of* $R_{\Theta JR}$ — The purpose of the test is to measure the thermal resistance of integrated circuits by using particular semiconductor elements on the chip to indicate the device junction temperature. In order to obtain a realistic estimate of the operating junction temperature, the whole chip in the package should be powered in order to provide the proper internal temperature distribution. During measurement of the junction temperature the chip heating power (constant voltage source) shall remain constant while the junction calibration current remains stable. It is assumed that the calibration current will not be affected by the circuit operation during the application of heating power.

The temperature-sensitive device parameter is used as an indicator of an average (weighted) junction temperature of the semiconductor element for calculations of thermal resistance. The measured junction temperature is indicative of the temperature only in the immediate vicinity of the element used to sense the temperature.

The temperature-sensitive electrical parameters generally used to indirectly measure the junction temperature are the forward voltage of diodes and the emitter-base voltage of bipolar transistors. Other appropriate temperature-sensitive parameters may be used for indirectly measuring junction temperature for fabrication technologies that do not lend themselves to sensing the active junction voltages.

3.2.2.1 Steady-state technique for measuring T_J. The following symbols shall apply for the purpose of these measurements:

I_M	Measuring current in milliamperes.
V_{MH}-	Value of temperature-sensitive parameter in millivolts, measured at I_M, and corresponding to the temperature of the junction heated by P_H.
T_{MC}-	Calibration temperature in degrees Celsius, measured at the reference point.
V_{MC}-	Value of temperature-sensitive parameter in millivolts, measured at I_M, and specific value of T_{MC}.

The measurement of T_J using junction forward voltage as the TSP is made in the following manner:

Step 1 — Measurement of the temperature coefficient of the TSP (calibration).

The coefficient of the temperature-sensitive parameter is generated by measuring the TSP as a function of the reference point temperature, for a specified constant measuring current, IM, by externally heating the device under test in an oven or in a fluid bath. The reference-point temperature range used during calibration shall encompass the temperature range encountered in the power application test (see Step 2). The measuring current is generally chosen such that the TSP decreases linearly with increasing temperature over the range of interest, and that negligible internal heating occurs in the silicon and metal traces. For determining the optimum TSP calibration or measuring current, V_{MC} vs. log I_M curves for two temperature levels that encompass the calibration temperature range of interest should be plotted. The optimum measuring current, I_M, is then selected such that it resides on the linear portion of the two V_{MC} vs. log I_M curves that were generated. A measuring current ranging from 0.05 to 5 mA is generally used, depending on the specifications and operating conditions of the device under test, for measuring the TSP. The value of the TSP temperature coefficient, V_{MC}/T_{MC}, for the particular measuring current used in the test, is calculated from the calibration curve, V_{MC} vs. T_{MC}. At least three points should be used to generate the voltage vs. temperature curve for the determination of the TSP temperature coefficient.

Step 2 — Power application test.

The power application test is performed in two parts. For both portions of the test, the reference point temperature is held constant at a preset value. The first measurement to be made is that of the temperature-sensitive parameter, i.e., V_{MC}, under operating conditions with the measuring current, I_M, used during the calibration procedure. The microelectronic device under test shall then be operated with heating power (P_H) applied. The temperature-sensitive parameter, V_{MH}, shall be measured with constant measuring current, I_M, that was applied during the calibration procedure (See Step 1).

The heating power, P_H, shall be chosen such that the calculated junction-to-reference point temperature difference as measured at V_{MH} is greater than or equal to 20°C. In accomplishing this, the device under test should not be operated at such a high heating power level that the on-chip temperature-sensing and heating circuitry is no longer electrically isolated. Care should also be taken not to exceed the design ratings of the package-interconnect system, as this may lead to an overestimation of the power being dissipated in the active area of the chip due to excessive power losses in the package leads and wire bonds. The values of V_{MH}, V_{MC}, and P_H are recorded during the power application test.

The following data shall be recorded for these test conditions:

a. Temperature-sensitive electrical parameters (V_F, V_{EB}, or other appropriate TSP).

b. Junction temperature, T_J, is calculated from the equation:

$$T_J = T_R + (V_{MH} - V_{MC}) \left| \frac{\Delta V_{MC}}{\Delta T_{MC}} \right|^{-1}$$

where $T_R = T_C$ or T_M

c. Case or mounting surface temperature, T_C or T_M.

d. Power dissipation, P_H.

e. Mounting arrangement (including package mounting force).

3.3 Calculations of $R_{\Theta JR}$

3.3.1 *Calculations of Package Thermal Resistance* — The thermal resistance of a microelectronic device can be calculated when the junction temperature, T_J, has been measured in accordance with procedures outlined in Sections 3.1 and 3.2.

With the data recorded from each test, the thermal resistance shall be determined from:

$$R_{\Theta JR} = \frac{T_J - T_R}{P_{H(package)}}, \text{ junction-to reference point,}$$

where $R_{QJR} = R_{QJC}$ or R_{QJM} and $T_R = T_C$ or T_M, respectively.

4 Summary Report

The following details shall be specified as appropriate:

a. Description of package, including thermal test chip, location of case or chip carrier temperature measurement(s), and heat sinking arrangement.

b. Test condition(s), as applicable (see Section 3).

c. Test voltage(s), current(s), and power dissipation of test chip.

d. Recorded data for each test condition, as applicable.

e. Symbol(s) with subscript designation(s) of the thermal characteristics determined.

f. Accept or reject criteria.

SEMI G31-0997
TEST METHOD FOR DETERMINING THE ABRASIVE CHARACTERISTICS OF MOLDING COMPOUNDS

1 Purpose

This document describes the method to measure the abrasive characteristics of molding compounds by measuring mold orifice weight loss as a function of molded volume.

2 Scope

2.1 All thermoset molding compounds used for microelectronic device encapsulation contain filler materials, typically 60–90% — which contribute to mold wear. Mold wear, typically at gates, is a major reason for mold rework. This test method may be used by suppliers to evaluate new molding materials or control current materials or by customers to evaluate the use of new materials. This test method provides a comparison of abrasiveness between materials.

2.2 This procedure can be used to determine the abrasive character of a given molding compound. Knowing the conditions of test, the results of the test, and the mold life experience (within one's own company) in the field, it is possible to judge if a molding compound is more or less abrasive to current compound in use.

3 Referenced Documents

3.1 Operational manuals for all equipment listed within this document.

3.2 Mold compound data sheets

4 Method

This procedure determines the abrasive character of a given filled molding compound by measuring orifice weight loss as a function of extruded volume.

5 Interferences

5.1 Care must be taken to avoid orifice weight loss by mishandling during placing and removing the orifice from the mold base.

5.2 Before the orifice is re-weighed after molding, carefully remove all contamination.

6 Equipment

6.1 Transfer molding press, 50 tons clamp minimum

6.2 Dielectric preheater

6.3 Orifice insert and mold assembly (See Figures 2–6.)

6.4 Mold base with pot diameter 1.75 to 2.00 inches

6.5 Photoelectric safety light screen

6.6 Stop watch

6.7 Pyrometer

6.8 Force gauge

6.9 Asbestos gloves

7 Procedure

7.1 *Equipment Set-Up* — Orifice Mold Installation (see Figure 1).

7.1.1 Place mold assembly on mold base and align orifice retainer opening with center of transfer pot.

7.1.2 Clamp bottom plate of mold assembly to bottom mold platen.

7.1.3 Set press limit switch to ensure clamp slow close is initiated 1" from completion of mold closing.

7.2 *Process Parameters*

7.2.1 Set up the molding parameters according to the material data sheet recommendations or expected use conditions, if known. These conditions include:

- Mold temperature
- Pre-heat temperature or pre-heat time
- Transfer speed
- Transfer pressure
- Clamp pressure
- Cure time

NOTE: The charge weight to be determined by trial molding shots to achieve a cull thickness between 0.060–0.120" and a suitable weight of extrudate.

7.3 *Operating Procedure*

7.3.1 Weigh orifice to one ten-thousandth of a gram. Record weight.

7.3.2 Verify process parameter settings.

7.3.3 Place orifice in orifice retainer and clamp mold assembly.

7.3.4 Preheat preformed material to the required temperature.

7.3.5 Insert preheated material into transfer pot and activate transfer ram (semi-automatic mode).

7.3.6 Start stopwatch when extrudate first appears. Record total extrusion time.

7.3.7 Collect and weigh extrudate to nearest one tenth of a gram. Record extrudate weight.

7.3.8 At the end of cure cycle, remove orifice from retainer. Loosen set-screws to split orifice and, with compressed air, blow out cured slug.

7.3.9 Ensure mating orifice halves are clean, realign the halves and tighten set screws.

7.3.10 Place orifice in retainer and repeat steps 7.3.4 through 7.3.9.

7.3.11 Repeat steps 7.3.4 through 7.3.10 until a minimum of 40 shots are run.

7.3.12 Record the following:

1. Original orifice weight
2. Shot number
3. Extruded weight per shot in grams
4. Cumulative extruded weight in grams
5. Orifice weight in grams
6. Orifice percent weight loss
7. Extrusion rate

8 Calculation

8.1 *Orifice Weight Loss*

$$\frac{I_O - I_N}{I_O}(100\%) = \%\text{ wt. loss}$$

I_O = Initial orifice weight to ten thousandth of a gram

I_N = Orifice weight after "N" number of shots to ten thousandth of a gram

8.2 Plot on linear graph paper the orifice weight loss vs. cumulative extruded weight.

8.3 Convert cumulative weight extruded to cumulative volume extruded.

Example: Molding compound density 2.0 g/cm^3 cumulative weight = 2000 g

$$2000\ g \times \frac{cm^3}{2.0\text{g}} = 1000\ cm^3$$

8.4 Convert cumulative volume extruded to equivalent production mold shots.

Example: 28 mm × 28 mm × 3.4 mm - 208 ld PQFP

Package Volume:

$$28\text{ mm} \times 28\text{ mm} \times 3.4\text{ mm x } \frac{\text{cm}^3}{1000\text{ mm}^3} = 2.6656\text{ cm}^3$$

Volume to shots:

$$1000\ \text{cm}^3 \times \frac{\text{shot}}{2.6656\text{ cm}^3} = 375\text{ shots}$$

8.5 Plot on linear graph paper the orifice weight loss vs. equivalent production mold shots.

SEMI G32-94
GUIDELINE FOR UNENCAPSULATED THERMAL TEST CHIP

1 Preface

This guideline details recommendations for a standardized thermal test chip design for referee test purposes. A sample data format for the test chip can be found in Appendix A. Based on the results of computer simulations of various chip-substrate configurations (Section 3.1), the following recommendations are made for the design of thermal test chips for VLSI package characterization (Section 3.2).

2 General Guideline

2.1 *Heat Sources* — The heat sources (i.e., transistors or resistor stripes), should use as much of the active chip area as possible so that the measured package thermal resistance is indicative of the chip size being used. A 10 mil (0.25 mm) parameter stripe (inactive area) should be sufficient for bonding pads and scribe lanes. It is desirable to use a range of test chip sizes so that the package thermal resistance can be determined as a function of chip size. A basic cell size of 75 mil (1.91 mm) square with a power dissipation capability of 7.5 to 10 W is recommended. The heat source area should exceed 85% of this basic cell active chip area. This basic cell could be arrayed or scaled up to a 450 mil (11.43 mm) square chip in increments of 75 mil (1.91 mm) on a side. For larger chip sizes, the basic cell size should be chosen so arrays can match the chip sizes in actual use. Since the larger chips can be 15—20 mm per side, the basic cell may need to be 5 mm per side, so a 3×3 array can be 15 mm square minimum.

2.2 *Spacing between Heat Sources* — The spacing between heat sources, which is needed to accommodate the temperature-sensing elements (i.e., p-n junctions), should be minimized. The spacing should be less than or equal to 2 mil (0.051 mm). The sensing element should be located at the center of the chip surface. For chips that are built up from an array of standard cells, sensing elements are also needed near a corner and between two adjacent corners (i.e., near or in the inactive regions), of the basic cell. Additional sensing elements for such purposes as die attachment evaluation and non-uniform power dissipation studies may be included as appropriate. All sensing elements and associated metallization runs must be electrically isolated from the heat sources.

2.3 *Thermal Test Chip Thickness* — The thermal test chip thickness should be between 18 mil (0.46 mm) and 22 mil (0.56 mm). For thin packages, the test chip thickness should be reduced to the normal die thickness for that package.

2.4 *Thermal Test Chip* — The thermal test chip should be designed such that its power dissipation limitations are consistent with the range of package thermal resistance encountered. This includes properly designed metallization runs such that for arrayed test chips, heating current for inner chips is routed so that wire runs from the package to inner chips are minimized. The ability to cause a chip surface-to-case temperature difference of at least 20°C is desirable. To accomplish this for silicon chips mounted on a variety of substrates (ranging from alumina to beryllia), the basic cell structure (i.e., 75 mil (1.91 mm) on a side) should dissipate a minimum of 7.5 W.

2.5 *Bond Pads* — Band pads (clear opening) should be equal to or greater than 4 mil (0.10 mm) on a side. Sensing and heating elements should not be connected to common bonding pads. Bonding pad location and size can or should be configured such that for arrayed test chips, chip-to-chip bonding is facilitated (i.e., bonding wire runs from the package to inner chips are minimized), but this is not mandatory for acceptable functional operation.

2.6 *Temperature-Sensing Diode/Diode Bridge Elements* — The temperature-sensing diode/diode bridge elements should be usable over the complete operating power and temperature range of the thermal test chip. The thermal test chip should function at junction temperature of 130°C minimum.

2.7 *Arrayed and Scaled Up Thermal Test Chips* — Pictorial representation of arrayed and scaled up thermal test chips are depicted in Figures 1 and 2, respectively. Heating elements (shaded areas) are transistors or resistor stripes connected in a variety of series-parallel combinations on as well as off the chip. The heating elements should fill as much of the shaded area as practical (consistent with the integrated circuit layout design rules).

APPENDIX A

Sample Data Format for an Unencapsulated Thermal Test Chip

A1 General Description (Select appropriate descriptors)

This device is an unencapsulated bipolar, MOS silicon chip, with metallized top, metallized top and bottom surface(s), with transistors or with metal film polysilicon, implanted, diffused resistors for heating, and with emitter-base transistor, diode p-n junctions for temperature-sensing in a diode/diode bridge arrangement. This device is designed for thermally characterizing integrated circuit packages.

A2 Mechanical Data

1. Show dimensioned drawing of chip indicating temperature-sensing and heating elements, on-chip interconnects, and bonding pad locations. Identify all bonding pads, indicate any bonding pads that must be connected to most negative or most positive external biases. State whether an electrically conductive connection to the bottom (back) surface of the chip is required for proper operation.
2. State chip thickness.
3. State all necessary handling and chip testing precautions.
4. State type of metallization used on chip top contact areas and on bottom mounting surface.
5. State type of junction passivation used and any special mounting ambient requirements. State preferred chip mounting and lead bonding procedures.
6. Show wire bonding configurations for various chip arrays and indicate heating power limits.

A3 Maximum Ratings

1. *Temperature*

   a. Storage temperature range, T_{stg}

   ______ °C to______°C

   b. Operating junction temperature range, T_J

   ______°C to______°C

2. *Voltage Over Operating Temperature Range*

   a. DC voltage applied to collector of heating transistors, or to heating resistors (limited by reverse voltage breakdown of substrate diode), V_H — _____ V

3. *Current Over Operating Temperature Range*

   a. DC current applied to collector of heating transistors, or to heating resistors, I_H — _____ A

A4 Electric Characteristics

1. *Temperature-Sensing Element (Diodes)*

   a. Reverse leakage current at T_A = _____ °C and V_R _____ V, I_R — _____ mA

   b. Forward measuring current range applied to sensing p-n junction over which temperature coefficient is linear, I_M — ______ mA to _____ mA

   c. Forward voltage drop at maximum measuring current and T_A = 25°C, V_M — _______ V

2. *Heating Element (Transistors or Resistors)*

   a. Forward current transfer ratio of transistor heating elements at maximum collector voltage and collector current at T_A = 25°C, h_{FE} — ______

   or,

   b. Resistance of resistor heating elements at T_A = 25°C, RH — ______ ohms

A5 Additional Information

The following information, which depends upon the mounting of the chip and connection of lead wires, is given only as an indication of the full electrical capability of the chip. No guarantee is to be inferred from the following information. When this chip is properly assembled in a ceramic integrated circuit package, the following electrical specifications for the heating elements may be expected:

Max. Power Rating at T_C=25°C, P_H — ______ W

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI G33-90
SPECIFICATION FOR PRESSED CERAMIC PIN GRID ARRAY PACKAGES

1 Preface

This specification defines the acceptance criteria for ceramic pin grid array packages produced using pressed ceramic, mechanically inserted pins and solder for electrical interconnection of pins.

2 Applicable Documents

2.1 *ANSI Specification*[1]

Y14.5 — Dimensioning and Tolerancing

2.2 *ASTM Specification*[2]

B 152 — Copper Metal Specification

2.3 *Federal Specification*[3]

*QQ-N-290*A — Nickel Plating

QQ-S-571E — Solder-Alloy Compositions

2.4 *Military Specifications*[3]

MIL-STD-105 — Sampling Procedures and Tables for Inspection by Attributes

MIL-STD-883 — Test Methods and Procedures for Microelectronics

MIL-G-45204 — Gold Plating, Electrodeposited

MIL-M-38510 — General Specification for Microcircuits

2.5 *JEDEC Specification*[4]

Pub. No. 95 — Registered and Standard Outlines for Semiconductor Devices

3 Selected Definitions

blister (bubble) ceramic — Any separation within the ceramic which does not expose underlying ceramic material.

blister (bubble) metal — Any localized separation within the metallization or between the metallization and ceramic which does not expose underlying metallization or ceramic material.

burr — An adherent fragment of excess parent material at the component edge.

chip — A region of ceramic missing from the surface or edge of a package which does not go completely through the package. Chip size is given by its length, width and depth from a projection of design planform (see Figure 1).

crack — A cleavage or fracture that extends to the surface of a package which may or may not pass through the entire thickness of the package.

contact pad — That metallized pattern that provides mechanical or electrical connection to the external circuitry.

die attach surface — A dimensional outline designated for die attach.

dielectric — A material applied to the surface of a package which provides such functions as electrical insulation, passivation of underlying metallization and limitation of solder flow.

discoloration — Any change in the color of the package metallization as detected by the unaided eye.

flatness — The allowable deviation of a surface from a reference plane. The tolerance zone is defined by two parallel planes within which the surface must lie.

footprint — Pin pattern.

foreign material — An adherent particle other than parent material.

isolation gap — Metal-free space between conductive areas.

peeling (flaking) — Any separation of metallization from the base material exposing the base material.

pit — Any unspecified depression in the package.

post-metallization — The process by which metallization is applied to a body (substrate) after the body has been fully sintered.

projection — An adherent fragment of parent material on the package surface.

pullback — The linear distance between the edge of the ceramic and the first measurable metallization and/or glass interface (see Figure 2).

refractory metallization — The process by which a high melting point (typically in excess of 1800°C) metal or

1 ANSI, 1430 Broadway, New York, NY 10018

2 American Society of Testing and Materials, 100 Barr Harbor Drive, West Conshohoken, PA 19428-2959

3 Military Standards, Naval Publications and Form Center, 5801 Tabor Avenue, Philadelphia, PA 19120

4 JEDEC, 2001 Eye Street N.W., Washington, D.C. 20006

combination of metals is applied to a suitable substrate and fired.

rundown — The vertical extension of metallization from the ceramic (see Figure 2).

seal area — A dimensional outline area designated to provide a surface for sealing.

seating plane — Defined by the standoff features or the package base plane if no standoff is used (see Figure 3).

SLAM — Abbreviation for "Single Layer Alumina Metallization," which denotes a package design without a physical die attach cavity.

solder — An alloy with a melting point equal to or less than 427°C.

standoff — The designed separation between the base plane and the seating plane created by a physical feature. Standoff use, configuration, and placement is optional (see Figure 3).

terminal — Case outline at point of entry or exit of an electrical contact.

thick film metallization — The process by which a thin layer of metal (usually in the 0.3 to 1.0 µm range) is applied to a suitable substrate by methods including sputtering, vacuum evaporation and chemical vapor deposition.

TIR — Total Indicator Reading.

window frame — A separate member of ceramic which is joined to the surface of the package on which a flat lid is attached for sealing.

4 Ordering Information

Purchase orders for pin grid array packages furnished to this specification shall include the following items:

1. Drawing number and revision level
2. Certification requirements
3. Quantity
4. Reference to this document
5. Any exceptions to print or specifications

5 Dimensions and Permissible Variations

The dimensions of the pin grid array package shall conform to SEMI Standards or to the customer drawing, and be within the outline of the appropriate JEDEC standard.

6 Material Parameters

The definitions, defects, and functional testing described in this specification relate directly to a nominal package made with the following materials. They may also be applicable to similar pin grid array packages made with other materials.

6.1 *Ceramic Properties*

6.1.1 *Materials* — Alumina content 90% minimum. Beryllia content to be in excess of 98.5% BeO.

6.1.2 *Color* — Dark or white.

6.2 *Metal Properties*

6.2.1 *Plating*

6.2.1.1 Plating finish shall be per MIL-M-38510; Nickel Plating (if designated) shall be per QQ-N-290A, 50 µ"–350 µ" (0.1300 mm–0.08890 mm). Gold plating (if desired) shall conform to MIL-G-45204, Type III and 50 µ"–225 µ" (0.1300 mm–0.05080 mm).

6.2.2 *Metallization*

6.2.2.1 Metallized circuits and areas can be thick film, thin film or refractory post-metallized. Such metallization materials may be, but are not limited to, the following:

1. *Thick Film Materials*
   a. Gold (Au) and Gold Alloys
   b. Silver (Ag)
   c. Silver - Platinum - Palladium (AgPtPd)
   d. Silver - Palladium - Platinum (AgPdPt)
   e. Copper (Cu)
2. *Thin Film Materials*
   a. Copper (Cu)
   b. Chromium (Cr)
   c. Nickel (Ni)
   d. Titanium (Ti)
4. *Refractory Materials*
   a. Molybdenum - Manganese (MoMn)
   b. Molybdenum - Tungsten (MoW)

6.2.3 *Solder* — Solder compositions used in the manufacture of pressed ceramic pin grid array packages shall include, but not be limited to, the following, per QQ-S-571E:

1. 10/90 — 10% Sn/90% Pb

2. 63/37 — 63% Sn/37% Pb

3. 10/88/2 — 10% Sn/88% Pb/2% Ag

6.2.4 *Pin Material* — CDA150, OFHC Copper, Zirconium alloy per ASTM B 152.

6.3 *Thick Film Dielectric* — An amorphous or polycrystalline glass or approved equivalent ranging in thickness from 0.013 mm (0.0005") to 0.038 mm (0.0015").

7 Defect Limits

A magnification of 10× shall be used to inspect the packages unless otherwise specified.

7.1 *Ceramic*

7.1.1 *Cracks* — Per MIL-STD-883, Method 2009.

7.1.2 *Chips* — (See Figure 1.)

7.1.2.1 *General*

7.1.2.1.1 *Corner* — Chips shall not exceed 0.762 mm (0.030") length × 0.762 mm (0.030") width × 0.762 mm (0.030") depth (see Figure 1-B).

7.1.2.1.2 *Edge* — Chips shall not exceed 1.52 mm (0.060") length × 0.635 mm (0.025") width × 0.635 mm (0.025") depth (see Figure 1-A).

7.1.2.1.3 Chips cannot encroach upon contact pad or penetrate metallization.

7.1.2.2 *Seal Area*

7.1.2.2.1 *Design With Window Frame* — Chips shall not exceed 0.635 mm (0.025") length × 0.635 mm (0.025") width × 0.635 mm (0.025") depth maximum. Chips cannot reduce the seal area width by more than 1/3 of the design width.

7.1.2.2.2 *Design Without Window Frame* — See Section 7.5 of this specification for dielectric inspection criteria.

7.1.2.3 *Cavity Edges*

7.1.2.3.1 Chips in the edges around the cavity shall not exceed 0.381 mm (0.015") along the edges or 0.127 mm (0.005") in depth.

7.2 *Package Flatness* — 0.004 inch/inch maximum

7.2.1 Seal Area Flatness

7.2.1.1 With Window Frame

Seal Area Size	*Seal Area Flatness (TIR)*
0–12.7 mm (0.000"-0.500")	0.051 mm (0.002") MAX
12.72–19.05 mm (0.501"-0.750")	0.076 mm (0.003") MAX
19.07 mm & greater (0.751")	0.101 mm (0.004") MAX

7.2.1.2 *Without Window Frame* — Flatness shall be 0.004" per inch maximum TIR.

7.2.2 *Die Attach Area Flatness*

Die Attach Area Size	*Die Attach Area Flatness (TIR)*
0–12.7 mm (0.000"-0.500")	0.051 mm (0.002") MAX
12.72–19.05 mm (0.501"-0.750")	0.088 mm (0.0035") MAX

7.3 *Metallization Misalignment (see Figure 2)*

7.3.1 *Metallization Rundown* — For the internal cavity shall not exceed 25% of the cavity depth, with a minimum of 0.127 mm (0.005") minimum isolation required.

7.3.2 *Wire Bond Finger Pullback* — 0.254 mm (0.010") maximum.

7.3.3 *Wire Bond Finger Rundown* — Not to exceed 1/3 of the ceramic cavity depth; 0.127 mm (0.005") isolation required.

7.3.4 *Pattern Isolation* — Dimension shall not be reduced by more than 50% of the design.

7.4 *Metallization Voids*

7.4.1 *Wire Bond Finger* — Must be free of voids or bare spots in the bonding area as defined by customer drawing.

7.4.2 *Die Attach Surface*

7.4.2.1 *SLAM Design* — Three voids are allowed, with a maximum of 0.127 mm (0.005") diameter separated by a distance greater than 0.254 mm (0.010"). Voids within 0.254 mm (0.010") of perimeter of die attach print area shall not be considered as the basis for rejection.

7.4.2.2 *Cavity Design* — Three voids are allowed with a maximum of 0.254 mm (0.010") diameter separated by a distance greater than 0.254 mm (0.010"). Voids within 0.381 mm (0.015") of die attach cavity wall shall not be considered as the basis for rejection.

7.4.3 *Solder*

7.4.3.1 *Pin Coating* — Solder wetting acceptability shall be per criteria in MIL-STD-883, Method 2003.

7.4.3.2 *Contact Pad Coating* — A minimum of 50% filleting must exist on the pin to pad solder joint with no exposed copper. A maximum of 0.889 mm (0.035") height of solder shall be allowed on pin to pad solder joints.

7.5 *Dielectric*

7.5.1 *Voids* — No single void in the dielectric shall expose two adjacent traces. Voids in the dielectric closer than 0.635 mm (0.025") shall not expose two adjacent traces.

7.5.2 *Contamination* — There shall be no contamination or foreign material upon dielectric with a diameter greater than 0.381 mm (0.015").

8 Sampling

Sampling size must meet the requirements of MIL-STD-105 or MIL-M-38510 or as agreed to between vendor and customer. Single, double, or multiple samples may be used per vendor and customer agreement.

9 Test Methods

9.1 Mechanical, electrical, and thermal test methods are per MIL-STD-883, unless otherwise noted.

9.1.1 *Lead Pull* — Under the test condition of five (5) pounds ± one quarter (1/4) pound, pull at an angle of 20° or less from the pins vertical line measured perpendicular to the package, there shall be no visible separation of the solder joint under 10× magnification.

9.1.2 *Lead Fatigue* — Shall be per MIL-STD-883, Method 2004, Test Condition B2, Paragraph 3.2.

9.2 *Functional Test Methods*

9.2.1 *Die Attach Quality* — Destructive die shear test shall be after environmental testing shall be per MIL-STD-883, Method 2019, Paragraph 3.2C.

9.2.2 *Wire Bond Quality* — Minimum pre-seal and post-seal bond strength test is per MIL-STD-883, Method 2011, Test Condition D. Reject for bonds which cause metallization to lift from the package or fail to meet minimum strength requirement.

9.2.3 *Solderability* — Per MIL-STD-883, Method 2003.

9.2.4 *Insulation Resistance Test* — Per MIL-STD-883, Method 1003, Condition D.

9.2.5 *Hermetic and Environmental Testing* — Per MIL-STD-883.

9.2.5.1 The hermetic integrity of the package must be maintained after all environmental testing. Hermetic checks shall comply with MIL-STD-883, Method 1014 Test Conditions A, B, C or D.

9.2.5.2 Environmental testing shall include, but not be limited to, the following:

1. Temperature Cycle per MIL-STD-883, Method 1010, Condition B.
2. Thermal Shock per MIL-STD-883, Method 1011, Condition B.
3. Centrifuge per MIL-STD-883, Method 2001, Condition E. Y1 axis only — cavity up; Y2 axis only — cavity down. (optional)
4. Mechanical Shock per MIL-STD-883, Method 2002, Condition B.
5. Vibration per MIL-STD-883, Method 2007, Condition A.

NOTE: Package applications requiring a heat sink attach will have the environmental tests (temperature cycle, shock, etc.) evaluated on an individual basis. The material, form factor and method of attachment used for heat sinks may result in severe stresses on the package assembly during environmental testing. Actual accelerated test requirements should be based on the expected product application environment and may be less stringent than those tests for packages without heat sinks.

10 Sequence of Events and Incoming Testing

During incoming inspection, the sequence of testing shall be:

1. Visual
2. Dimensional
3. Functional
   a. Die Attach
   b. Wire Bond
   c. Pre-Seal Wire Pull
   d. Seal
   e. Heat Sink Attach (if applicable)
   f. Environmental Test
   g. Fine Leak, MIL-STD-883, Method 1014, Condition B
   h. Gross Leak, MIL-STD-883, Method 1014, Condition C
   i. Post-Seal Bond Pull
   j. Radiography
   k. Die Shear, MIL-STD-883, Method 2019
   l. Solderability, MIL-STD-883, Method 2003

NOTE: An initial vendor qualification may be performed on the thermal and electrical characteristics of the package. The characteristics tested will be:

Insulation Resistance — Per MIL-STD-883, Method 1003, Test Condition D.

Thermal Dissipation — Per MIL-STD-883, Method 1012.

11 Packaging and Marking

11.1 *Packaging* — Containers selected shall be strong enough and suitably designed to provide maximum protection against crushing, spillage, and other forms of damage to the container or its contents or contamination from exposure to excessive moisture or oxidation by gases. Packaging materials shall be so selected to prevent any contamination of the ceramic component parts with fibers or organic particles.

11.2 *Marking* — The outer containers shall be clearly marked identifying the customer part number, customer purchase order number, drawing number (optional), quantity, date, and vendor lot number (optional).

SEMI G34-89
SPECIFICATION FOR CER-PACK PACKAGE CONSTRUCTIONS, INCLUDING LEADFRAMES, SUITABLE FOR AUTOMATED ASSEMBLY BY END USERS

1 Preface

This specification defines the standard requirements for Cer-Pack package construction intended for automated assembly to printed wiring boards. Acceptance criteria for package constructions, including leadframes, are included.

2 Applicable Documents[1]

2.1 This document specifically refers to:

MIL-STD-883 — Test Methods and Procedures for Microelectronics

2.2 Related information may also be found in:

MIL-M-38510 — General Specification for Microcircuits

3 Selected Definitions

burr — A fragment of excess material or foreign particle adhering to the surface.

chip — Region of ceramic missing from the surface or edge of a package which does not go completely through the package. Chip size is given by its length, width, and depth from a projection of the design plan-form (see Figure 1).

crack — Cleavage or fracture that extends to the surface of a package. It may or may not pass through the entire thickness of the package.

critical seal area — The area bound by the shortest line from the cavity corners to the ceramic edge (see Figure 2).

critical seal path — The nominal design distance across the critical seal area from the die cavity to ceramic edge.

fin — A fine, feathery-edged projection on the edge or corner of the ceramic.

glass flow — Heated sufficiently to remove all screen mesh marks visible at 10× magnification.

non-critical seal area — Those portions of the sealing surface falling outside the critical area (see Figure 2).

overhang — Horizontal extension of glass from the ceramic (see Figure 3).

projection — Raised portion of the surface indigenous with the parent material.

pull back — Defines a dimension covering the linear distance between the edge of the ceramic and the first measurable glass interface (see Figures 3, 4, and 5).

rundown — Vertical extension of glass from the ceramic (see Figure 3).

seal area — A dimensional outline area designated for sealing the base and cap together to provide a hermetic seal (see Figure 5).

void — An absence of metallization or glass from a designated metallized or glassed area on the ceramic surface.

4 Ordering Information

Purchase order for Cer-Pack package devices furnished to this specification shall include the following items:

1. Drawing number and revision level
2. Type and color of ceramic
3. Type and thickness of glass
4. Type and thickness of metallization
5. Description
6. Certification by vendor
7. Method of test and measurements (see Section 9)
8. Lot acceptance procedures (see Section 8)
9. Packaging and marking (see Section 10)
10. Lead finish requirements (see Section 6.5)

5 Dimensions and Permissible Variations

Packaged device dimensions shall conform to JEDEC JC-11 registered outline dimensions for Cer-Packs for Automated Assembly.

6 Materials

6.1 *Ceramic*

6.1.1 Alumina content to be 90% minimum.

1 Military Standards, Naval Publications and Form Center, 5801 Tabor Avenue, Philadelphia, PA 19120

6.1.2 *Color* — Black, dark brown, or dark violet.

6.2 *Sealing Material* — Solder glass designed to form a hermetic seal. Glass type and temperature/time profile shall be specified.

6.3 *Die Attach Pad* — Gold (or other suitable material).

6.4 *Leadframe* — Fully annealed Alloy 42.

6.5 *Lead Finish* — Unless otherwise specified, hot tin-lead solder dip, Type A, per MIL-M-38510, to within 0.030" of lead seal on plated leads, and 100% coverage if applied directly over base metal.

7 Defect Limits

7.1 *Ceramic*

7.1.1 *Cracks* — Cracks are not allowed.

7.1.2 *Chips* — See Figures 1 and 2.

7.1.2.1 *Corner Chips* — 0.762 mm (0.030") × 0.762 mm (0.030") × 25% of package element thickness.

7.1.2.2 *Edge Chips* — 2.54 mm (0.060") × 0.762 mm (0.030") × 25% of package element thickness.

7.1.2.3 *Critical Seal Area* — Chips cannot reduce the critical seal path to less than half the nominal design dimension at any point. No more than four chips are allowed in the critical seal area.

7.1.3 *Burrs, Projections, and Fins*

7.1.3.1 *Cap* — 0.127 mm (0.005") maximum.

7.1.3.2 *Base* — 0.076 mm (0.003") maximum.

7.1.3.3 *Die Attach Surface* — 0.025 mm (0.001") maximum above metallization excluding a 0.254 mm (0.010") perimeter.

7.1.4 *Camber* — 0.050 mm (0.002") camber permitted up to maximum of 0.004 inch/inch (mm/mm).

7.2 *Glass*

7.2.1 *Chips or Voids* — Chips in the glass or missing glass is allowed, provided the region of the chipped or missing glass meets the minimum specified glass thickness after melting the glass as specified.

7.2.2 *Glass Misalignment* — (after glass flow) (see Figure 3.)

7.2.2.1 *External Overhang* — 0.127 mm (0.005") maximum.

7.2.2.2 *External Rundown* — 30% of ceramic thickness maximum.

7.2.2.3 *Pullback* — See Table 1 and Figures 2, 3, and 4.

Table 1 Maximum Allowable Pullback

Side external (critical seal)	0.010" (2.54 mm)
Side external (other)	0.015" (0.381 mm)
End external	0.020" (0.508 mm)
Side cavity	0.010" (0.254 mm)
End cavity	0.010" (0.254 mm)

NOTE: Maximum allowable critical seal area reduction on any one side between side cavity and side external shall not reduce critical seal path to less than 0.635 mm (0.025").

8 Sampling

Sampling will be determined between supplier and purchaser.

9 Functional Test Methods

9.1 *Die Attach Quality*

9.1.1 Visually inspect preform wetout after die attach. Minimum fillet shall be 75% of the die perimeter.

9.1.2 Perform destructive die shear test post environmental testing per MIL-STD-883, Method 2019.

9.1.3 Inspect to reveal voids in the die attach eutectic alloy or approved silver-filled glass per MIL-STD-883, Method 2012.

9.2 *Lead Bond Quality* — Perform minimum pre-seal and post-seal bond strength test per MIL-STD-883, Method 2011, Test Condition D. Reject for bonds causing the metallization to lift from the leadframe post.

9.3 *Hermetic Environmental Testing*

9.3.1 The hermetic integrity of the package must be maintained after all environmental testing. Hermetic check shall comply with MIL-STD-883, Method 1014, Test Condition A, or B and C.

9.3.2 Environmental testing shall include, but not be limited to, the following:

9.3.2.1 Temperature Cycle per MIL-STD-883, Method 1010, Condition C.

9.3.2.2 Thermal Shock per MIL-STD-883, Method 1011, Condition B.

9.3.2.3 Centrifuge per MIL-STD-883, Method 2001, Condition D, Y axis only.

9.3.2.4 Moisture Resistance per MIL-STD-883, Method 1004.

9.4 *Die Attach Material Thickness* — Die attach material thickness shall be measured by standard cross-sectioning without smearing.

9.5 *Solderability* — Per MIL-STD-883, Method 2003.

9.6 *Sequence of Events and Incoming Testing* — During incoming inspection, the sequence of testing shall be:

1. Frame Attach
2. Die Attach
3. Bond (if applicable)
4. Seal
5. Lead Finish (Type A per MIL-M-38510)
6. Environmental Testing
7. Lead Trim
8. Fine Leak
9. Gross Leak
10. Torque Test (test method pending)
11. Bond Pull
12. Die Shear (optional)

9.6.1 *Solderability* — A separate sample with lead finish Type A shall be subjected to preconditioning of Class B time/temperature exposure per burn-in Test Method 1015, MIL-STD-883, then tested to Method 2003.

NOTE: An initial qualification on the thermal and electrical characteristics of the package may be performed. The characteristics tested will be:

Insulation Resistance — Per MIL-STD-883, Method 1003, Test Condition B.

Thermal Dissipation — Per MIL-STD-883, Method 1012.

10 Packaging and Marking

10.1 *Packaging* — Containers selected shall be strong enough and suitably designed to provide maximum protection against crushing, spillage, and other forms of damage to the container or its contents. Containers shall afford protection of the contents from contamination and exposure to excessive moisture or oxidation by gases. Packaging materials shall be so selected to prevent any contamination of the ceramic component parts with paper fibers or organic particles.

10.2 *Marking* — The outer containers shall be clearly marked to identify the user stock number, user purchase order number, drawing number, quantity, vendor lot number, and solder glass type.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI G35-87
SPECIFICATION FOR TEST METHODS FOR LEAD FINISHES ON SEMICONDUCTOR (ACTIVE) DEVICES

1 Scope

This specification shall be used by suppliers and/or users of semiconductor (active) devices, and is effective for all lead finishes used.

2 Purpose

This specification establishes uniform methods and procedures for conducting tests on lead finishes on (active device) electronic packages. Other SEMI standards establish materials used and the finishes for them.

3 Applicable Documents

3.1 *Order of Precedence* — In the event of a conflict between the text of this specification and the references cited herein, the text of this specification shall take precedence.

3.2 *Referenced Documents* — Unless otherwise specified, the following standards and specifications, with appropriate issue letter at time of order entry, form a part of this specification to the extent and for the purpose specified herein.

3.3 *ASTM Specifications*[1]

E 10 — Standard Test Method for Brinell Hardness for Metallic Materials

E 122 — Choice of Sample Size to Estimate the Average Quality of a Lot or Process

E 384 — Standard Test Methods for Micro-Hardness of Materials

B 487 — Measuring Metal and Oxide Coating Thickness by Microscopical Examination of a Cross Section

B 545 — Standard Specification for Electro Deposited Coatings of Tin

B 567 — Measurement of Coating Thickness by the Beta Backscatter Principle

B 568 — Measurement of Coating Thickness by X-Ray Spectrometry

3.4 *Military Specifications*[2]

MIL-STD-883 — Test Methods and Procedures for Microelectronics

MIL-STD-105 — Sampling Procedures with Tables for Inspection by Attributes

3.5 *SEMI Specifications*

SEMI G4 — Integrated Circuit Leadframe Materials Used in the Production of Stamped Leadframes

SEMI G18 — Integrated Circuit Leadframe Materials Used in the Production of Etched Leadframes

SEMI G20 — Lead Finishes for Plastic Packages (Active Devices Only)

4 Selected Definitions

active devices — semiconductor devices with active function (e.g., IC, transistor, diode) as opposed to passive devices (e.g., inductors, capacitors).

air atmosphere — air heated to specified temperature which, when cooled to ambient, will normalize to one (1) standard atmosphere.

steam atmosphere — atmosphere in a closed vessel containing water, with venting sufficient to maintain temperature at one (1) standard atmosphere and 100° + 0, -5°C.

NOTE: The intent of this requirement is to replace air with steam.

5 Sampling

Unless otherwise specified, Practice E 122 shall be used. When so specified, appropriate sample sizes shall be selected from each lot in accordance with MIL-STD-105. Each quality characteristic shall be assigned an acceptable quality level (AQL) and lot tolerance percent defective (LTPD) value in accordance with MIL-STD-105 definitions for critical, major, and minor classifications. If desired and so specified in the contract or order, each of these classifications may alternatively be assigned cumulative AQL and LTPD values. Inspection levels shall be agreed upon between the user and supplier.

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohoken, PA 19428-2959

2 Military Standards, Naval Publications and Form Center, 5801 Tabor Avenue, Philadelphia, PA 19120

6 Test Methods

6.1 *Visual Inspection*

6.1.1 For reference purposes the required appearance and associated properties for any specific lead finish are specified in the detailed SEMI specification for the specific lead finish to be evaluated.

6.1.2 *Purpose*

6.1.2.1 Visual inspection shall be performed to evaluate application of the required lead finish. Magnification at 10× preferred.

6.1.3 *Failure Criteria*

6.1.3.1 Finish is wrong type, is missing, or is non-adherent (has peeling, flaking, or blistering).

NOTE: Variations in color are not cause for failure unless there is evidence of corrosion and flaking or pitting.

6.1.3.2 Finish contains foreign material or surface contamination such as water marks.

6.1.3.3 Leads and terminations shall be electrically sound and mechanically intact. Nothing in the lead finish shall detract from lead integrity.

6.2 *Solderability*

6.2.1 The purpose of the test, terms and definitions, apparatus, and materials to be used are specified in MIL-STD-883, Method 2003.

6.2.2 Procedure to be used shall be as specified in MIL-STD-883, Method 2003, except as specified below.

6.2.2.1 Aging as specified in MIL-STD-883, Method 2003, shall not be performed. (See Section 6.2.2.2.)

6.2.2.2 At user's option, pre-aging at the indicated level below shall be performed:

1. Condition A — No pre-age.
2. Condition B — 5 hours at 150°C in Air Atmosphere.
3. Condition C — 5 hours at 200°C in Air Atmosphere.
4. Condition D — 4 hours suspended in Steam Atmosphere.
5. Condition E — 8 hours suspended in Steam Atmosphere.

NOTE: See definition section for above noted atmospheric conditions.

6.2.3 Failure criteria shall be as specified in MIL-STD-883, Method 2003, except as specified below.

6.2.3.1 Coverage shall be 90% on major flat (excluding non-functional areas). Non-functional areas include end of termination, edges in clad materials, and areas above the seating plane.

6.3 *Lead Fatigue/Lead Finish Adherence*

6.3.1 The purpose of the test, apparatus, and procedure to be used are as specified in MIL-STD-883, Method 2004, Test Condition B1, except as specified below.

6.3.1.1 Purpose of this test is limited to a check of lead finish integrity after stressing.

6.3.1.2 Three (3) leads per device shall be tested.

6.3.1.3 Three (3) cycles of rotation shall be used.

6.3.2 *Failure Criteria*

When examined at 10× magnification, any evidence of peeling, or gross discontinuity shall be considered a device failure.

6.4 *Thickness*

6.4.1 Thickness, when specified, shall be measured in functional lead area. On flat leads, measure in the center of the major flat. On round leads, measure below the seating plane and above the gauge plane.

6.4.2 Thickness, when specified, shall be measured in accordance with ASTM B 568 (Measurement of Coating Thickness by X-Ray Spectrometry) as the preferred method.

6.4.3 Thickness may be measured as an alternative to the above by either ASTM B 567 (Beta Backskatter Principle) or ASTM B 487 (Cross Section Principle).

6.5 *Hardness*

6.5.1 Hardness, when specified, shall be measured in functional lead area. On flat leads, measure in the center of the major flat. On round leads, measure below the seating plane and above the gauge plane.

6.5.2 Hardness shall be tested only when specified as a Lead Finish Detail (e.g., for socketing application).

6.5.3 Hardness shall be tested in accordance with ASTM E 384 (Standard Test Methods for Micro-Hardness of Materials), or ASTM E 10 (Standard Test Method for Brinnel Hardness for Metallic Materials), whichever is appropriate (see detailed specification or procurement document).

7 Certification

7.1 Upon request of the purchaser in the contract or order, a manufacturer's or supplier's certification that the material was manufactured and tested in accordance with this specification, together with a report of the test results, shall be furnished at the time of shipment.

7.2 In the interest of controlling inspection costs, the supplier and the purchaser may agree that the material shall be certified as capable of meeting certain requirements. In this context, capable of meeting shall signify that the supplier is not required to perform the appropriate tests in Section 6. However, if the user performs the test and the material fails to meet the requirement, the material may be subject to rejection.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI G36-88

SPECIFICATION FOR DIMENSIONS AND TOLERANCES USED TO MANUFACTURE PLASTIC MOLDED HIGH DENSITY TAB QUAD SEMICONDUCTOR PACKAGE TOOLING

1 Preface

This document is for the ordering of tooling required to mold and form plastic high density TAB quad semiconductor packages. It is to be used by packaging engineers, mold manufacturers, and end-of-line toolmakers as the basis for defining the limits of manufacturing tolerances.

2 Applicable Documents

2.1 *ANSI Specification*[1]

Y14.5 — Dimensioning and Tolerancing

2.2 *JEDEC Specification*[2]

Pub No.95 — JEDEC Registered and Standard Outline and Standard Outline for Semiconductor Devices

2.3 *Military Specification*[3]

MIL-STD-100 — Engineering Drawing Practices

3 Selected Definitions — Product Criteria Tolerance Limits

mismatch and offset — defined with respect to package only. All statements will be equally applicable in two (2) axes. All mismatch and offset measurements are made after molding and prior to trimming.

cavity to frame offset — will be measured prior to any trimming operation. Offset will be defined as the difference in bottom cavity position with respect to a leadframe datum. The offset measurement will exclude leadframe tolerances (see Figure 2).

top to bottom cavity mismatch — characterized by the fact that the top and bottom cavities in the mold are not aligned properly, causing a mismatch condition. The measurement shall be stated as the difference in the top cavity position relative to the bottom cavity position (see Figure 1).

package warpage — any non-linear dimensional change from the mold cavity characteristic, usually caused by incorrect package design or molding practices (see Figure 3).

1 ANSI, 1430 Broadway, New York, NY 10018

2 JEDEC, 2001 Eye Street N.W., Washington, D.C. 20006

3 Military Standards, Naval Publications and Form Center, 5801 Tabor Avenue, Philadelphia, PA 19120

parting line protrusions — those plastic excesses which remain as a normal characteristic after normal molding, deflashing, trimming, and singulation (see Figure 4).

top, bottom protrusions — those plastic excesses (includes ejector pin crowns) which remain as a normal characteristic extending from the smooth surface of the molded package.

variations in lead location — defined with respect to a 90° angle from the top or bottom of the smooth surface of the molded package as viewed on the end or side projections (see Figure 4).

lead shoulder intrusions and protrusions — any variations in straightness along the defined shoulder essentially caused by dambar removal (see Figure 4).

lead position overlay (footprint) — (See Figure 5.)

shoulder bend location — measured from the outermost point of the shoulder bend radius (see Figure 6).

lead co-planarity — defined as the vertical lead position with respect to a reference plane measured after forming. The reference plane is defined by the three lowest leads from the bottom of the package (see Figure 6).

4 Ordering Information

4.1 Purchase orders for tooling for plastic molded high density TAB semiconductor packages furnished to this specification shall include the following items:

1. A package tooling outline drawing showing all required dimensions listed in Section 5. Package surface finish to be included.
2. A list of any tolerance limits which differ from those in Section 6.
3. The type of tooling steel required.
4. The type of leadframe material and temper to be used.
5. The type of plastic to be molded (if proprietary, a statement of its shrinkage characteristics) and molding temperature.
6. Sampling plan shall be determined between vendor and purchaser.
7. The number of spare parts or expendable parts desired.

8. Molding press to be used.

9. Electrical power available for heating.

10. Applicable leadframe drawing, including all dimensions.

5 Dimensions

5.1 Drawing must show dimensions for the following items, if applicable:

1. Package length
2. Package width
3. Top cavity thickness
4. Bottom cavity thickness
5. Frame thickness
6. Top ejector pin locations from datum lines
7. Bottom ejector pin locations from datum lines
8. Ejector pin sizes (top and bottom)
9. Ejector depth (top and bottom, draft angle top and bottom side)
10. Pin 1 ID location from package center
11. Pin 1 ID shape and size
12. All applicable package radii
13. Draft angles (top and bottom)
14. Package parting line location
15. Shoulder bend location

6 Product Criteria

6.1 Dimensional tolerance limits for high density TAB products (see Section 3).

6.1.1 Recognizing that every manufacturing process is subject to variation, the following list details the acceptable limit of this variation:

28-328 LEAD

OVERLAP/OFFSET	
Cavity Overlap (See Figure 1)	0.002" (maximum)
Cavity Mismatch (See Figure 1	0.002" (maximum)

CAVITY TO FRAME OFFSET	
(See Figure 2) (not including leadframe tolerances)	0.002" (maximum)

PACKAGE WARPAGE	
Warp factor (See Figure 3)	2.5 to a max. of 0.003"

PROTRUSIONS & INTRUSIONS	
(See Figure 4) Parting line	0.005" (maximum)
Gating	0.005" (maximum)
Top or bottom ejector pin	0.002" (maximum)

VARIATIONS IN LEAD POSITION	
(See Figure 4)	0.003" (maximum)

LEAD COPLANARITY	
(See Figure 6)	0.002" (maximum)

DAMBAR TRIMMING INTRUSIONS/PROTRUSIONS	
Intrustions (See Figure 6)	0.002" (maximum)
Protrusions (See Figure 4) (shall not decrease gap more than 20%)	0.003" (maximum)

7 Packaging

Tooling must be packed in containers designed and constructed to prevent damage and/or contamination.

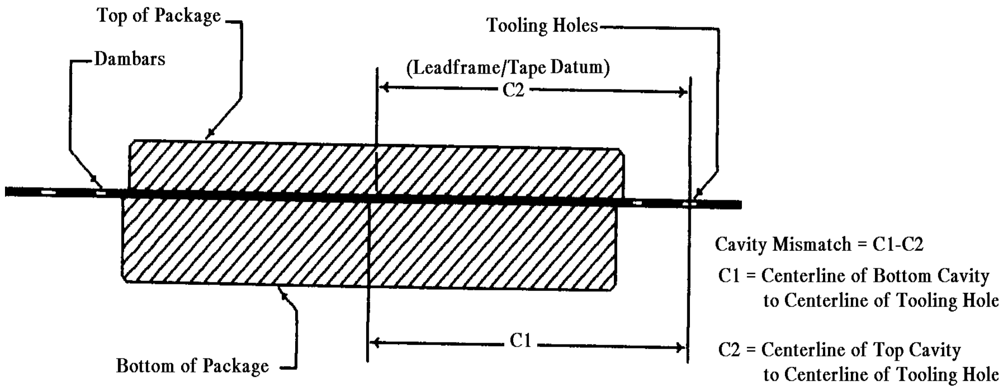

Figure 1
Top to Bottom Cavity Mismatch

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI G37-88
SPECIFICATION FOR DIMENSIONS AND TOLERANCES USED TO MANUFACTURE PLASTIC MOLDED SMALL OUTLINE PACKAGE TOOLING

1 Preface

This document is a guideline for the ordering of tooling required to mold and form plastic molded small outline semiconductor packages. It is to be used by packaging engineers, mold manufacturers, and end-of-line toolmakers as the basis for defining the limits of manufacturing tolerances.

2 Applicable Documents

2.1 *ANSI Specification*[1]

Y14.5 — Dimensioning and Tolerancing

2.2 *JEDEC Specification*[2]

Pub. No. 95 — Registered and Standard Outline for Semiconductor Devices

2.3 *Military Specification*[3]

MIL-STD-100 — Engineering Drawing Practices

3 Selected Definitions — Product Criteria Tolerance Limits

mismatch and offset — defined with respect to package only. As this family of packages has four sides, all statements will be equally applicable in two (2) axes. All mismatch and offset measurements are made after molding and prior to trimming.

cavity to frame offset — will be measured prior to any trimming operation. Offset will be defined as the difference in bottom cavity position with respect to a leadframe datum. The offset measurement will exclude leadframe tolerances (see Figure 1).

top to bottom cavity mismatch — characterized by the fact that the top and bottom cavities in the mold are not aligned properly, causing a mismatch condition. The measurement shall be stated as the difference in the package top cavity position relative to the bottom cavity position (see Figure 2).

parting line protrusions — those plastic excesses which remain as a normal characteristic after normal molding, deflashing, trimming, and singulation (see Figure 3).

top or bottom protrusions — those plastic excesses (includes ejector pin crowns), which remain as a normal characteristic extending from the smooth surface of the molded package.

variations in lead location — defined with respect to a 90° angle from the top or bottom of the smooth surface of the molded package as viewed on the end or side projections (see Figure 3).

lead shoulder intrusions and protrusions — any variations in straightness along the defined shoulder essentially caused by dambar removal (see Figure 3).

package warpage — any non-linear dimensional change from the mold cavity characteristic, usually caused by incorrect package design or molding practices (see Figure 4).

shoulder bend location — measured from the outermost point of the shoulder bend radius (see Figure 5).

lead co-planarity — defined as the vertical lead position with respect to a reference plane measured after forming. The reference plane is defined by the three lowest leads from the bottom of the package (see Figure 6).

4 Ordering Information

4.1 Purchase orders for tooling for plastic molded high density TAB semiconductor packages furnished to this specification shall include the following items:

1. A package tooling outline drawing showing all required dimensions listed in Section 5. Package surface finish to be included.
2. A list of any tolerance limits which differ from those in Section 6.
3. The type of tooling steel required.
4. The type of leadframe material and temper to be used.
5. The type of plastic to be molded (if proprietary, a statement of its shrinkage characteristics).
6. Sampling plan for compliance to Section 7.
7. The number of spare parts or expendable parts desired.

---

1 ANSI, 1430 Broadway, New York, NY 10018

2 JEDEC, 20001 Eye Street, N.W., Washington, D.C. 20006

3 Military Standards, Naval Publications and Form Center, 5801 Tabor Avenue, PA 19120

8. The type of molding press to be used, including power requirements.
9. Applicable leadframe drawing, including all dimensions.

5 Dimensions

5.1 Drawing must show dimension for the following items, if applicable:

1. Package length
2. Package width
3. Top cavity thickness
4. Bottom cavity thickness
5. Frame thickness
6. Ejector top locations from cavity centerline
7. Ejector bottom locations from cavity centerline
8. Ejector size (top and bottom)
9. Ejector depth (top and bottom, draft angle top side, bottom side, and end)
10. End notch shape, depth, width, length
11. Pin 1 ID location from package center
12. Pin 1 ID shape and size
13. Corner radius or sides
14. Corner radius or ends
15. Lead spread (nominal)
16. Shoulder bend location
17. Shoulder width

6 Product Criteria — Dimensional Tolerance Limits for S.O. Packages

6.1 In recognizing that every manufacturing process is subject to variation, the following list details the acceptable limit of this variation:

CAVITY MISMATCH	
(See Figure 2)	0.05 mm (0.002")

PACKAGE/FRAME OFFSET	
(See Figure 1), (excluding leadframe tolerances)	0.05 mm (0.002")

MOLDED PROTRUSIONS	
(See Figure 3) Parting line	0.15 mm (0.006")
Top or bottom	0.025 mm (0.001")

VARIATION IN LEAD LOCATION	
(See Figure 3)	0.101 mm (0.004")

SHOULDER INTRUSIONS AND PROTRUSIONS	
Intrusions	0.025 mm (0.001")
Protrusions*	0.004"

PACKAGE WARPAGE	
Warp factor:	2.5

LEAD CO-PLANARITY	0.003" (maximum)

EJECTOR PIN DEPTH	0.003"

* Assumes 0.002" design protrusion.

7 Sampling

Samples used to determine compliance to Section 6 shall be determined between user and supplier.

8 Packaging

Tooling must be packed in containers designed and constructed to prevent damage and/or contamination. Specific protection must be provided if tooling is to be shipped any great distance.

SEMI G38-0996
TEST METHOD FOR STILL- AND FORCED-AIR JUNCTION-TO-AMBIENT THERMAL RESISTANCE MEASUREMENTS OF INTEGRATED CIRCUIT PACKAGES

1 Purpose

The purpose of this test is to determine the thermal resistance of integrated circuit packages using thermal test chips.

2 Scope

This test method deals only with junction-to-ambient measurements of thermal resistance and limits itself to still- and forced-air convection testing environments.

3 Referenced Documents

3.1 *SEMI Specifications*

SEMI G32 — Guideline for Unencapsulated Thermal Test Chip

SEMI G42 — Specification for Thermal Test Board Standardization for Measuring Junction-to-Ambient Thermal Resistance of Semiconductor Packages

4 Terminology

The following definitions and symbols shall apply for the purpose of this test:

4.1 *ambient temperature (T_A, in degrees Celsius)* — The ambient temperature is the temperature of the air at a specified location in the vicinity of the microelectronic device under test (DUT).

4.2 *junction temperature (T_J, in degrees Celsius)* — The term is used to denote the temperature of the semiconductor junction in the microcircuit in which the major part of the heat is generated. For purposes of this test, the measured junction temperature is only indicative of the temperature in the immediate vicinity of the element used to sense the temperature.

4.3 *power dissipation (P_H, in watts)* — The heating power applied to the device causing a junction-to-reference point temperature difference.

4.4 *temperature-sensitive parameter (TSP)* — The temperature-dependent electrical characteristic of the junction under test which can be calibrated with respect to temperature and subsequently used to detect the junction temperature of interest.

4.5 *thermal resistance* — Junction to specified reference point, $R_{\theta JR}$ degrees Celsius/watt. The thermal resistance of the microcircuit is the temperature difference from the junction to some reference point in the ambient divided by the power dissipation P_H.

4.6 *velocity (v_A, in linear feet per minute (LFPM))* — The velocity of the air at a specified location upstream of the DUT.

5 Apparatus

The apparatus required for these tests shall include the following as applicable to the specified test procedures.

5.1 *Thermocouple Material* — Shall be copper constantan (type T) or equivalent, for the temperature range -100 to + 300°C. The wire size shall be no larger than AWG size 30. The junction of the thermocouple shall be welded to form a bead rather than soldered or twisted. The accuracy of the thermocouple and associated measuring system shall be ± 0.5°C.

5.2 *Suitable Electrical Equipment* — As required to provide controlled levels of conditioning power and to make the specified measurements. The instrument used to electrically measure the temperature-sensitive parameter shall be capable of resolving a voltage change of 0.5 mV.

5.3 *Controlled Temperature Chamber, Fluid Bath, or Wind Tunnel* — Capable of maintaining the specific reference point temperature to within ± 0.5°C of the reset (measured) value. Typical still-air enclosure and wind tunnel assemblies are presented for reference purposes only.

5.4 *Still-Air Enclosure Assembly* — The microcircuit shall be mounted in a cubic enclosure of not less than 0.028 m^3 (1.0 ft^3). There shall be no radiation sources other than the microcircuit under test in the enclosure. The interior enclosure wall shall have a high reflectance finish (emissivity < 0.1). The ambient temperature should be measured by means of a thermocouple mounted at a distance of approximately 2.54 cm (1.0 in) beneath the DUT and 1.27 cm (0.5 in) from the test board or socket.

5.4.1 The microcircuit shall be mounted in such a manner that conduction cooling through the leads or the test socket or both shall be small compared to the other cooling mechanisms. No. 36 AWG wire should be connected to the device test socket. The air flow (by natural convection) should be unrestricted above and beneath the device. An alternative approach would be to use a mounting arrangement that approximates an application environment. Such a reference mounting configuration can be found in Specification, Thermal Test Board Standardization for Measuring Junction-to-Ambient Thermal Resistance of Semiconductor Packages. Device mounting and test board positioning inside the measuring chamber are depicted in Figure 1.

5.5 *Wind Tunnel Assembly* — A typical wind tunnel design is shown with its dimensions in Figure 2.

5.5.1 The fan or blower should be placed downstream of the DUT as depicted in Figure 2. A static pressure differential measurement across a calibrated nozzle is used to calculate the wind tunnel air velocity, while a thermocouple is used to measure the ambient temperature upstream of the DUT. Both of these devices should be placed at a specified location upstream of the DUT, as shown in Figure 2. The thermocouple is located in the center of the wind tunnel, 5.08 cm (2.0 in) from the test section and 2.54 cm (1.0 in) above the center plane of the DUT.

5.5.2 The microcircuit shall be mounted in such a manner that conduction cooling through the leads or the test socket, or both, shall be small compared to the other cooling mechanisms. To minimize conduction through the leads, No. 36 AWG wire should be connected to the device test socket. The DUT should be aligned so that the air front is parallel to the longer edge of the package (air front hitting the package side). An alternative approach would be to use a mounting arrangement that approximates an application environment. Such a referee mounting configuration can be found in SEMI G42. Device mounting and test board orientation inside the wind tunnel are depicted in Figure 3.

5.5.3 Flow straighteners should be placed upstream of the DUT, as shown in Figure 2. The flow straighteners should provide a flat velocity profile across the test section of the wind tunnel. This will ensure that the DUT is exposed to a uniform velocity across its entire cross section. A typical velocity profile for well-developed turbulent flow is depicted in Figure 3.

5.5.4 Calibrated hot wire anemometer or nozzle with suitable pressure gauges (p_1 and p_2) for measuring the pressure difference across the nozzle is used to calculate the wind tunnel air velocity. When using the nozzle, the pressure differential across the calibrated nozzle is measured using a liquid monometer, typically in inches of water.

5.5.5 Hot wire anemometer capable of verifying the air velocity profile with an accuracy of ± 5%. The velocity sensor should disrupt the airflow as little as possible.

6 Procedure

6.1 *Measurement of Wind Tunnel Air Velocity, v_A* — The air velocity measurement techniques are direct method and indirect method.

6.1.1 *Direct Measurement of Wind Tunnel Air Velocity* — The direct method is based on a measurement by a hot wire anemometer in wind tunnel.

6.1.2 *Indirect Measurement of Wind Tunnel Air Velocity, vA* — The air velocity measurement technique is an indirect method based on a pressure differential measurement across a calibrated nozzle. The actual velocity of interest is derived from a calibration curve relating the pressure differential of the nozzle to the volume (or mass) flow rate of the air through the nozzle. The required air velocity (in linear feet per minute) is then calculated by dividing the volume flow rate (in cubic feet per minute) by the cross sectional area at the entrance of the DUT test section (in square feet). The volume flow rate shall be determined to within an accuracy of ± 10%.

6.1.2.1 *Air Flow Profile* — Hot wire anemometer should be used to verify that the flow profile of the air front, measured within 5.08 cm (2.0 in.) of the test section, does not vary by more than 10% across the center 90% of the test section. The DUT and mounting board/socket should not be in the test section when the flow profile is determined.

6.2 *Direct Measurement of Reference Point Temperature, T_S* — For the purpose of measuring the still-air junction-to-ambient microelectronic device thermal resistance in a chamber, the ambient temperature ($T_R = T_A$) should be measured with a thermocouple beneath the DUT. For purposes of measuring forced air junction-to-ambient thermal resistance in a wind tunnel, the ambient temperature should be measured with a thermocouple upstream of the DUT in the section of the tunnel that experiences fully developed flow.

6.3 *Thermal Resistance, Junction to Specified Reference Point, $R_{\theta JR}$.*

6.3.1 *General Considerations* — The thermal resistance of a semiconductor device is a measure of the ability of its carrier, or package and mounting technique to provide for heat removal from the semiconductor junction. The thermal resistance of a microelectronic device can be calculated when the ambient temperature and power dissipation in the device and a measurement of the junction temperature are known. When making the indicated measurements, the package shall be considered to have achieved thermal equilibrium when halving the time between the application of power and the taking of the reading causes no error in the indicated results within the required accuracy of measurement.

6.3.2 *Indirect Measurement of Junction Temperature for the Determination of $R_{\theta JA}$* — The purpose of the test is to measure the thermal resistance of integrated circuits by using particular semiconductor elements on the chip to indicate the device junction temperature. In order to obtain a realistic estimate of the operating junction temperature, the whole chip in the package should be powered in order to provide the proper internal temperature distribution. During measurement of the junction temperature, the chip heating power (constant voltage source) shall remain constant while the junction calibration current remains stable. It is assumed that the calibration current will not be affected by the circuit operation during the application of heating power.

6.3.3 The temperature-sensitive device parameter is used as an indicator of an average (weighted) junction temperature of the semiconductor element for calculations of thermal resistance. The measured junction temperature is indicative of the temperature only in the immediate vicinity of the element used to sense the temperature.

6.3.4 The temperature-sensitive electrical parameters generally used to indirectly measure the junction temperature are the forward voltage of diodes and the emitter-base voltage of bipolar transistors. Other appropriate temperature-sensitive parameters may be used for indirectly measuring junction temperature for fabrication technologies that do not lend themselves to sensing the active junction voltages.

6.3.4.1 *Steady-State Technique for Measuring T_J* — The following symbols shall apply for the purpose of these measurements:

I_M	Measuring current in milliamperes.
V_{MH}	Value of temperature-sensitive parameters in millivolts, measured at I_M, and corresponding to the temperature of the junction heated by P_H.
T_{MC}	Calibration temperature in degrees Celsius, measured at the reference point.
V_{MC}	Value of temperature-sensitive parameter in millivolts, measured at I_M and specific value of T_{MC}.

The measurement of T_J, using junction forward voltage as the TSP, is made in the following manner:

Step 1 — Measurement of the temperature coefficient of the TSP (calibration).

The coefficient of the temperature-sensitive parameter is generated by measuring the TSP as a function of the reference point temperature, for a specified constant measuring current, I_M, by externally heating the device under test in a controlled temperature oven or fluid bath. The reference point temperature range used during calibration shall encompass the temperature range encountered in the power application test (see Step 2). The measuring current is generally chosen such that the TSP decreases linearly with increasing temperature over the range of interest and that negligible internal heating occurs in the silicon and metal traces. For determining the optimum TSP calibration or measuring current, V_{MC} vs. log I_M curves for two temperature levels that encompass the calibration temperature range of interest should be blotted. The optimum measuring current, I_M, is then selected such that it resides on the linear portion of the two V_{MC} vs. log I_M curves that were generated. A measuring current ranging from 0.05 to 5 mA is generally used, depending on the specifications and operating conditions of the device under test for measuring the TSP. The value of the TSP temperature coefficient, V_{MC}/T_{MC}, for the particular measuring current used in the test, is calculated from the calibration curve, V_{MC} vs. T_{MC}. At least three points should be used to generate the voltage vs. temperature curve for the determination of the TSP temperature coefficient.

Step 2 — Power application test

The power application test is performed in two parts. For both portions of the test, the reference point temperature and the specified air velocity are held constant at a preset value. The first measurement to be made is that of the temperature-sensitive parameter (i.e., V_{MC}, under operating conditions with the measuring current, I_M, used during the calibration procedure). The DUT shall then be operated with heating power (P_H) applied. The temperature-sensitive parameter, V_{MH}, shall be measured with constant measuring current, I_M, that was applied during the calibration procedure (see Step 1).

The heating power, P_H, shall be chosen such that the calculated junction-to-reference point temperature difference as measured at V_{MH} is greater than or equal to 20°C. In accomplishing this, the device under test should not be operated at such a high heating power level that the on-chip temperature sensing and heating circuitry is no longer electrically isolated. Care should also be taken not to exceed the design ratings of the package-interconnect system, as this may lead to an overestimation of the power being dissipated in the active area of the chip due to excessive power losses in the package leads and wire bonds. The values of V_{MH}, V_{MC}, and P_H are recorded during the power application test.

The following data shall be recorded for these test conditions:

a. Temperature-sensitive electrical parameters (V_F, V_{EB}, or other appropriate TSP).

b. Junction temperature, T_J, is calculated from the equation:

$$T_J = T_R + \left(V_{MH} - V_{MC}\right)\left|\frac{\Delta V_{MC}}{\Delta T_{MC}}\right|^{-1}$$

where $T_R = T_A$

c. Ambient (air) temperature, T_A.

d. Ambient (air) velocity, v_A, (v_A = 0 for still-air enclosure).

e. Power dissipation, P_H.

f. Mounting arrangement (including offset from test board).

6.4 *Calculations of $R_{\theta JR}$*

6.4.1 *Calculation of Package Thermal Resistance* — The thermal resistance of a microelectronic device can be calculated when the junction temperature, T_J, has been measured in accordance with procedures outlined in Sections 6.1 through 6.3. With the data recorded from each test, the thermal resistance shall be determined from:

$$R_{\theta JR} = \frac{T_J - T_R}{P_{H(Package)}}$$

where : $R_{\theta JR} = R_{\theta JA}$ and $T_R = T_A$.

7 Summary Report

The following details shall be specified:

1. Description of Package

1.1 Package Type

Package Name ________________ (per JEDEC or EIAJ)

Pin Counts ________________ pins

Special Specification ________________ Yes ________________ No

If Yes, describe the detail specification.

____

____

____

1.2 Test Chip

Chip per SEMI G32 ________________ Yes ________________ No

Chip Size ________________ mm x ________________ mm

Chip Thickness ________________ mm

1.3 Leadframe

Leadframe Material Fe/Ni Alloy, Cu, Cu Alloy, Other (____________)

Leadframe Thickness ________________ mm

Die Pad Size ________________ mm x ________________ mm

1.4 Package Dimension & Compound

Package Size ________________ mm x ________________ mm

Package Thickness ________________ mm

Compound Material ____

1.5 Others

Die Attach Material ____

Heat Sink/Spreader ________________ Yes ________________ No

If yes, describe the configuration, dimension, method of attachment, location, etc.

____

SEMI G39-89
SPECIFICATION FOR BRAZED LEAD FLATPACK CONSTRUCTIONS, INCLUDING LEADFRAMES, SUITABLE FOR AUTOMATED ASSEMBLY

1 Preface

This specification defines the standard requirements for co-fired ceramic brazed lead flatpack package constructions intended for automated assembly to printed wiring boards. Acceptance criteria for package constructions, including leadframes, are included.

2 Applicable Documents

2.1 *ANSI Standard*[1]

ANSI Y14.5 — Dimensioning and Tolerancing

2.2 *Federal Specification*[2]

QQ-N-290 — Nickel Plating

2.3 *JEDEC Standard*[3]

JEDEC Pub 95 — Registered and Standard Outlines for Solid State Products

2.4 *Military Specifications*[2]

MIL-M-38510 — General Specifications for Microcircuits

MIL-STD-1051 — Sampling Procedures and Tables for Inspections by Attributes

MIL-STD-23011 — Iron Nickel Alloys for Sealing to Glass and Ceramics

MIL-STD-45204 — Gold Plating Electrodeposited

MIL-STD-87883 — Brazing

MIL-STD-883 — Test Methods and Procedures for Microelectronics

3 Selected Definitions

blister bubble (ceramic) — any separation within the ceramic which does not expose underlying ceramic material.

blister bubble (metal) — any localized separation within the metallization or between the metallization and ceramic which does not expose underlying metal or ceramic material.

bond finger — a region of refractory metallization within the package cavity intended for wirebonding to a mirocircuit die pad.

braze — an alloy with a melting point equal to or greater than 600°C.

burr — an adherent fragment of excess parent material at the component edge.

chip-out — a region of ceramic missing from the surface or edge of a package which does not go completely through the package. Chip-out size is given by its length, width, and depth from a projection of the design plan-form (see Figure 1).

co-fired — a process or technology for manufacturing products in which the ceramic and refractory metallizations are fired simultaneously.

contact pad — that metallized pattern to which the leadframe is brazed.

crack — a cleavage or fracture, internal or external.

die attach surface — a designated dimensional outline area intended for die attach (see Figure 2).

foreign material — an adherent particle other than parent material of that component.

layer — a dielectric sheet with or without metallization that performs a discrete function as part of the package construction.

lead offset — alignment of leads across the package.

peeling (flaking) — any separation from the basis material that exposes the basis material.

projection — an adherent fragment of excess material on the component surface.

pullback — the linear distance between the edge of the ceramic and the first measurable metallization surface (see Figure 3).

rundown — the linear distance down a vertical surface from the top to the point of maximum metallization overhang (see Figure 3).

seal area — a dimensional outline area designated for either metallization or bare ceramic to provide a surface area for lid sealing (see Figure 2).

terminal — metallization at the point of electrical contact to package interior circuitry; also the brazing surface for a lead.

1 ANSI, 1430, Broadway, New York, NY 10018

2 Military Standards, Naval Publications and Form Center, 5801 Tabor Avenue, Philadelphia, PA 19120

3 JEDEC, 2001 Eye Street, N.W., Washington, D.C. 20006

TIR — total Indicator Reading; the span of readings from minimum to maximum of a given dimension over the total surface to which it applies.

void (ceramic) — an absence of screen printed ceramic from a designated area greater than 0.075 mm (0.003") in diameter.

void (metal) — an absence of refractory metallization, braze or plating material from a designated area greater than 0.075 mm (0.003") in diameter.

4 Ordering Information

4.1 Purchase orders for co-fired ceramic brazed lead flatpack packaged devices shall specify the following information:

1. Quantity.
2. Drawing number and revision level or date.
3. Reference to this specification.
4. Any exception to drawing or specification.

4.2 Drawings for co-fired ceramic brazed lead flatpack packaged devices shall specify the following information:

1. Drawing number and revision level.
2. Number of terminals and terminal center line pacing.
3. Lead material, finish, and dimensions.
4. Ceramic material color and composition; and refractory metal type.
5. Type and thickness of plating on both device body and leads.
6. Dimensioning and tolerancing per ANSI Y14.5.
7. Internal bonding pattern.
8. Lead number 1 position.
9. Method of test and measurements.
10. Electrical, mechanical and environmental requirements.

5 Dimensions and Permissible Variations

Packaged device dimensions shall conform to JEDEC JC-11 registered outline dimension drawings for Co-fired Ceramic Brazed Lead Flatpack Devices for Automated Assembly, unless otherwise specified.

6 Materials

6.1 *Ceramic*

6.1.1 *Alumina Content* — To be 90% minimum. Beryllia content to be 99% minimum.

6.1.2 *Color* — To be black, dark brown, or dark violet unless otherwise specified.

6.2 *Metals* — External metal surfaces shall be in accordance with MIL-M-38510.

6.3 *Braze* — Copper/silver per MIL-STD-7883.

6.4 *Refractory Metallization* — To be per MIL-M-38510, Type C.

6.5 *Leadframe* — Fully annealed iron nickel cobalt alloy (per MIL-M-38510, Type A) or iron nickel alloy (per MIL-M-38510, Type B).

6.6 *Microcircuit Finishes* — Shall be per MIL-M-38510 unless otherwise specified.

7 Incoming Testing Sequence

1. Visual inspection.
2. Dimensional check.
3. Electrical parameter testing.
4. Sampling testing of plating quality, die attach, die shear, wire bond pull, seal, hermeticity, lead integrity, and solderability.

8 Visual Criteria (10× Magnification)

8.1 *Cracks* — None allowed per MIL-STD-883, Method 2009.

8.2 *Chip-Outs*

8.2.1 *Corner* — 0.762 mm (0.030") × 0.762 mm (0.030") × 1 tape layer, maximum.

8.2.2 *Edge* — 2.54 mm (0.100") × 0.762 mm (0.030") × 1 tape layer, maximum.

8.2.3 *Encroachment* — No encroachment upon seal areas, bonding fingers, or external terminal areas permitted. Chips that expose any buried metallization are not permitted.

8.3 *Burrs, Projections, and Blisters* — Must fit within outline limits.

8.3.1 *Top Plane* — excluding seal area — 0.102 mm (0.004"), maximum.

8.3.2 *Unmetallized Seal Area* — 0.0762 mm (0.003"), maximum.

8.3.3 *Metallized Seal Area* — 0.025 mm (0.001"), maximum.

8.3.4 *Bottom Surface* — 0.051 mm (0.002"), maximum.

8.3.5 *Edges* — 0.152 mm (0.006"), maximum.

8.3.6 *Terminal Pads* — 0.051 mm (0.002"), maximum.

8.3.7 *Wire Bond Fingers* — 0.025 mm (0.001"), maximum.

8.3.8 *Die Attach Surface Flatness* — 0.025 mm (0.001"), maximum.

8.4 *Camber* — .004 inch/inch (mm/mm), maximum. For dimensions less than 10.5 mm (0.750"), 0.127 mm (0.003") camber is permitted along any planar dimension of the device package.

8.5 *Seal Area Flatness* — The seal area shall be within the limits listed in Table 1.

8.6 *Die Attach Surface Flatness* — The die attach surface shall be flat within the limits listed in Table 2.

Table 1 Seal Ring Flatness Limits

Seal Ring O.D.	*Seal Ring Flatness*
0—6.35 mm (0–0.250")	0.051 mm max. (0.002")
6.37—12.7 mm (0.251"–0.500")	0.051 mm max. (0.002")
12.72—25.40 mm (0.501"–1.000")	0.101 mm max. (0.004")
25.40 mm (1.000")	0.101 mm/mm (0.004"/in.)

Table 2 Die Attach Area Flatness Limits

Die Attach Pad Dimension	*TIR Flatness*
0—12.7 mm (0—0.500")	0.051 mm max. (0.002")
12.72—19.5 mm (0.501"—0.750")	0.088 mm max. (0.0035")

8.7 *Voids*

8.7.1 *Seal Area Voids* — A maximum of 3 voids permitted. Not more than two voids per side of 0.010" diameter. Any two voids must be separated by 0.762 mm (0.030") minimum, not to degrade the seal width by more than 25%.

8.7.2 *Terminal Void* — A maximum of two voids per terminal pad permissible. Maximum void diameter acceptable is 0.254 mm (0.101). Voids may never reduce the minimum terminal width to less than 2/3 of the nominal design dimension.

8.7.3 *Wire Bond Finger Voids* — Void free 0.015" back from the bond finger tip.

8.7.4 *Die Attach Surface Voids* — Three voids of 0.010" diameter are the maximum allowed separated by 0.030" minimum.

NOTE — Voids 0.015" from the cavity wall not included.

8.7.5 *Internal Metallization Voids* — Voids in internal metallization planes or traces shall not break continuity. Specific requirements for resistance and capacitance parameters shall be specified in the purchase order, if applicable.

8.8 *Pattern Metallizations*

8.8.1 *Seal Plan Rundown (internal cavity)* — Not to exceed 25% of the cavity layer thickness.

8.8.2 *Seal Plan Rundown (external to cavity)* — Not to exceed half the nominal design distance to adjacent edge metallization. In no event shall the rundown be closer than 0.254 mm (0.010") to any edge metallization.

8.8.3 *Wire Bond Rundown* — Wire bond finger rundown shall not exceed 25% of the cavity depth or 0.005" (0.127 mm) whichever is smaller.

8.8.4 *Wire Bond Finger Pullback* — Wire bond finger pullback shall not exceed 0.127 mm (0.005") from the nominal design dimension for finger end to cavity edge.

8.8.5 *Seal Plane Pullback* — Seal plane pullback shall not exceed 0.127 mm (0.005") from the nominal design dimension for seal plane metallization to edge.

8.9 *Lead Attachment*

8.9.1 *Voids in Braze* — Braze fillets must be 95% free of voids, shall not cause voids under a lead.

8.9.2 *Lead Offset* — Lead centerlines must be aligned to within 0.127 mm (0.005") of the centerlines of corresponding braze pad metallizations. Side to side within 0.010".

8.9.3 *Lead-to-Lead Misalignment* — To exceed 10% of nominal spacing.

8.9.4 *Dimensional Criteria* — Per JEDEC JC-11 registered outline drawings in JEDEC Publication 95, or as specified on the user drawings.

9 Sampling

Sample size must meet requirements of MIL-STD-105 or MIL-M-38510 as agreed to between user and supplier.

10 Test Methods (Mechanical, Electrical, and Thermal)

10.1 *Gold Plating Thickness* — Shall conform to MIL-STD-45204. Gold thickness may be determined using the Beta Backscatter Radiation Method, X-Ray Fluorescence or by Cross Sectioning.

10.2 *Nickel Plating* — Shall conform to QQ-N-290. Nickel thickness may be determined using the Beta Backscatter Radiation Method, X-Ray Fluorescence, or by Cross Sectioning.

10.3 *Destructive Die Shear Testing* — Shall be performed per Method 2019 of MIL-STD-883.

10.4 *Wire Bond Pull Testing* — Shall be performed per Method 2011, Condition D of MIL-STD-883.

10.5 *Temperature Cycling Testing* — Shall be performed per Method 1010, Condition C of MIL-STD-883.

10.6 *Thermal Shock Testing* — Shall be performed per Method 1011, Condition C of MIL-STD-883.

10.7 *Constant Acceleration Testing* — Shall be performed per Method 2001, Condition E, Y axis only, of MIL-STD-883.

10.8 *Mechanical Shock Testing* — Shall be performed per Method 2002, Condition B of MIL-STD-883.

10.9 *Insulation Resistance Testing* — Shall be performed per Method 1003 of MIL-STD-883.

10.10 *Internal Water Vapor Content Testing* — Shall be performed per Method 1018 of MIL-STD-883.

10.11 *Hermeticity Testing* — Shall be performed per Method 1014, Condition A of MIL-STD-883. The hermetic integrity of the packaged device must be maintained after all testing.

10.12 *Lead Integrity Testing* — Shall be performed per Method 2004, Condition A, B1, and B2 of MIL-STD-883.

10.13 *Solderability Testing* — Shall be performed per Method 2003 of MIL-STD-883.

10.14 *Moisture Resistance Testing* — Shall be performed per Method 1004 of MIL-STD-883.

11 Packaging and Marking

11.1 *Packaging* — Containers selected shall be strong enough and suitably designed to provide maximum protection against crushing, spillage and other forms of damage to the container or its contents. Container shall afford protection of the contents to contamination from exposure to excessive moisture or oxidation by gases. Packaging material shall be so selected to prevent any contamination of the ceramic component parts with fibers or organic particles.

11.2 *Marking* — The outer containers shall be clearly marked identifying:

1. Supplier part number.
2. User part number.
3. Quantity.
4. Date of manufacture.
5. Supplier lot number.

12 Applicability

This specification is intended to apply to construction utilizing the tall brazed lead flatpack outlines included in JEDEC Publication 95.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI G41-87
SPECIFICATION FOR DUAL STRIP SOIC LEADFRAME

1 Preface

This specification is a guideline for high volume production of leadframes, including internal package plating, for plastic molded S.O. semiconductor packages. It is a design guideline for packaging engineers, leadframe stampers and mold manufacturers and has been developed to meet the requirements of automated assembly.

2 Applicable Documents

2.1 *SEMI Specifications*

SEMI G4 — Integrated Circuit Leadframe Materials used in the Production of Stamped Leadframes

SEMI G10 — Mechanical Measurement for Plastic Package Leadframes

2.2 *Military Specifications*[1]

MIL-STD-105 — Sampling Procedures and Tables for Inspection by Attributes

MIL-STD-883 — Test Methods and Procedures for Microelectronics

3 Selected Definitions

burr — a fragment of excess material either horizontal or vertical attached to the leadframe.

camber — curvature of the leadframe strip edge (see Figure 1).

coil set — longitudinal bowing of the leadframe (see Figure 2).

coined area — that area at the tip end of the bond fingers coined to produce a flattened area for wire bond (see Figure 3).

crossbow — transverse bowing of the leadframe (see Figure 4).

functional area — the die attach pad and the lead tips.

lead twist — angular rotation of bonding fingers (see Figure 5).

pits — shallow surface depressions or craters in the leadframe material.

slug marks — random dents in the leadframe caused by foreign material in the stamping die.

stamped leadframe terminology — (See Figure 6.)

Z plane — lead and pad planarity require a reference in the Z dimension. The recommendation for the reference plane, hereafter called the Z plane, is the average of the two dambars when measured at their geometric center. This reference method is incorporated into SEMI G10.

4 Ordering Information

4.1 Purchase orders for leadframes for plastic molded S.O. packages furnished to this specification shall include the following items:

1. Part specification number and revision level
2. Material
3. Number of leads
4. Material certification
5. Packaging and marking (see Section 8)

5 Dimensions

See Table 1 and Figure 7.

6 Defect Limits and Parameters (See SEMI G10 for Measurement Methods)

6.1 *Internal Frame Area*

6.1.1 *Minimum Flat Wire Bonding Area* — 80% of nominal lead width and 0.381 mm (0.015") in length.

6.1.2 *Coin Depth*

6.1.2.1 0.20 mm (0.008") material: 0.013 mm (0.0005") minimum/0.02 mm (0.001") maximum.

6.1.2.2 0.25 mm (0.010") material: 0.013 mm (0.0005") minimum/0.05 mm (0.002") maximum.

NOTE: Maximum coin depth may also be constrained by minimum lead spacing requirement given in Section 6.1.3. Minimum coin depth may also be constrained by minimum bond area requirement given in Section 6.1.1.

6.1.3 *X-Y Plane Lead Spacing and Location*

6.1.3.1 Spacing between leads to be 0.152 mm (0.006") minimum.

6.1.3.2 Leads to be located so that a 0.007" diameter circle centered on the nominal center of the coined lead in width and 0.152 mm (0.006") back from lead tip in length shall be totally encompassed by the coined area.

---

1 Military Standards, Naval Publications and Form Center, 5801 Tabor Avenue, Philadelphia, PA 19120

6.1.4 *X-Y Plane Die Attach Pad Location* — Die attach pad to be located within ± 0.151 mm (0.002") as measured from the centerline of the reference hold in the side rail.

6.1.5 *Lead Twist* — Shall not exceed 330 or 0.015 mm (0.0006") per 0.254 mm (0.010") of lead width.

6.1.6 *Die Attach Pad Tilt and Flatness*

6.1.6.1 *Tilt* — 0.025 mm (0.001") maximum per 2.54 mm (0.100") in the undepressed state. 0.051 mm (0.002") maximum per 2.54 mm (0.100") in the depressed condition.

6.1.6.2 *Flatness* — 0.0005 mm (0.0002") when measuring from the center to the average of the four corners. The corners are defined at 0.127 mm (0.005") from each edge.

6.1.7 *Die Attach Pad Downset* — ± 0.051 mm (0.002") as measured from the center of the pad to a point on the bar support strip. The nominal downset recommended is 0.30 mm (0.012") for 0.25 mm (0.010") thick material and 0.20 mm (0.008") for 0.20 mm (0.008") thick material.

6.1.8 *Lead and Die Attach Pad Coplanarity*

6.1.8.1 *Coplanarity* — The relationship between the leads and die attach pad is the axis relationship of these parts to the Z plane.

6.1.8.2 *Lead Planarity* — The lead tips as measured in the center of the back, uncoined surface of the lead tip shall be located within the following tolerances of the Z plane: Lead Planarity: ± 0.004".

6.1.8.3 *Die Attach Pad Planarity* — The die attach pad when measured at the center must be within the following tolerances of the Z plane: Pad Planarity: ± 0.003"/-0.005".

6.2 *External Area and Strip*

6.2.1 *Material*

6.2.1.1 0.20 mm (0.008") material thickness recommended for 0.300" wide packages.

6.2.1.2 0.25 mm (0.010") material thickness recommended for 0.300" wide packages.

6.2.1.3 Nominal thickness tolerances shall be ± 0.008 mm (0.0003").

6.2.1.4 *Width Tolerance* — ± 0.051 mm (0.002").

6.2.2 *Coil Set* — Maximum of 3.175 mm (0.125") measured in a free standing state over strip length.

6.2.3 *Crossbow* — crossbow shall not exceed the following dimensions: Maximum Crossbow ± 0.127 mm (0.005").

6.2.4 *Camber* — Shall not exceed 0.05 mm (0.002") over a gauge length of 150 mm (6.00"). (See SEMI G10, Section 8).

6.2.5 *Progression* — The progression over strip length shall be within ± 0.051 mm (0.002") of nominal.

6.2.6 *Burrs* — Burrs shall be firmly attached and able to withstand a probe force of 10 grams. Vertical burrs inside the dambar shall not exceed 0.02 mm (0.001"). Vertical burrs outside the dambar and horizontal burrs in any location shall not exceed 0.05 mm (0.002").

6.2.7 *Pits and Slug Marks*

6.2.7.1 Within functional area and on external leads there shall be no slug marks. Pits shall not exceed .008 mm (0.0003") in depth and 0.013 mm (0.0005") in largest surface dimension in these areas.

APPLICATION NOTE: There is a question regarding the ability of material suppliers to meet this specification. Revision of this specification is under review.

6.2.7.2 *Areas Other than 6.2.7.1* — Pits and imperfections shall not affect leadframe strength regardless of size and shall not exceed 0.05 mm (0.002") in depth and 0.07 mm (0.005") in largest surface dimension.

6.2.8 *Strip Cutoff Location* — Strip cutoff shall be within ± 0.05 mm (0.002") of basic strip length.

7 Sampling

Sampling will be determined between user and supplier.

8 Packaging and Marking

8.1 *Packaging* — Leadframes must be packed in containers designed and constructed to prevent damage and/or contamination. Specific protection must be provided against foreseeable mechanical and environmental hazards.

8.2 *Marking* — The outer containers shall be clearly marked, identifying the user stock number, user purchase order number, drawing number, and vendor lot number within the carton.

SEMI G42-0996
SPECIFICATION FOR THERMAL TEST BOARD STANDARDIZATION FOR MEASURING JUNCTION-TO-AMBIENT THERMAL RESISTANCE OF SEMICONDUCTOR PACKAGES

NOTE: This entire document was revised in 1996.

1 Purpose

This document provides the requirements for a standard thermal resistance test board to be used in junction- to-ambient thermal resistance measurement of a semiconductor package under still- and forced-air condition as a referee method.

2 Scope

2.1 This document describes the thermal resistance test board for measurement of the following packages:

Dual-In-Line Packages (DIP)

Plastic Chip Carrier Package (PCC)

Quad Flat Package (QFP)

Pin Grid Array Package (PGA)

Ball Grid Array Package (BGA)

2.2 This document uses SI units.

3 Referenced Documents

Information regarding the methods for measuring junction-to-ambient thermal resistance, the proper design and use of thermal test chips, and material specifications for printed circuit boards, can be found in the applicable documents listed below.

3.1 *SEMI Specifications*

SEMI G32 — Guideline for Unencapsulated Thermal Test Chip

SEMI G38 — Test Method for Still- and Forced-Air Junction-to-Ambient Thermal Resistance Measurements of Integrated Circuit Packages

3.2 *Military Specifications*[1]

MIL-P-13949 — Material Specification for NEMA Grade G-10 Printed Circuit Board Material

MIL-STD-883C — Method 1012.1, Thermal Characteristics

4 Terminology

4.1 *junction temperature,* T_J — In degrees Celsius is used to denote the temperature of the semiconductor junction in the microcircuit in which the major part of the heat is generated. Usually the measured junction temperature is only indicative of the temperature in the immediate vicinity of the element used to sense the temperature.

4.2 *junction-to-ambient thermal resistance,* $R_{\theta JA}$ — In degrees Celsius/watt is the temperature difference between the junction and the ambient, divided by the power dissipation P_H.

4.3 *power dissipation,* P_H — In watts is the heating power applied to the device causing a junction-to-reference point temperature difference.

4.4 *temperature sensitive parameter, TSP* — Is the temperature dependent electrical characteristic of the junction under test which can be calibrated with respect to temperature and subsequently used to detect the junction temperature of interest.

5 Ordering Information

The material required for making the thermal test board can be ordered through any electronic supply store.

6 Requirements

General requirements regarding the materials used for test board, the specified physical dimensions of the test board and other necessary conditions are described in the following paragraphs:

6.1 *Material Requirements*

6.1.1 The test board material should be NEMA Grade G-10 or equivalent.

6.1.2 The conductor traces on the board must be copper and the total amount of copper should not exceed 20% of the surface area of the board.

6.1.3 The vias should be plated through.

6.1.4 External wire connections from the package leads to edge connector leads must be made with 24-gauge copper wire.

1 Military Standards, Naval Publications and Form Center, 5801 Tabor Avenue, Philadelphia, PA 19120

6.2 *Thermal Test Board Physical Dimensions and Layout* — Five separate boards are designed for the purpose of thermal measurements of different types of semiconductor packages.

6.2.1 *Physical Dimensions*

6.2.1.1 *Length* — 114.3 mm ± 0.254 (4.50 inches ± 0.01)

6.2.1.2 *Width* — 76.2 mm ± 0.254 (3.00 inches ± 0.01)

6.2.1.3 *Thickness* — 1.524 – 1.651 mm ± 0.127 mm (0.060 – 0.065 inches ± 0.005 inches)

6.2.2 *Layout*

6.2.2.1 *Dual-in-Line Packages or Sockets (see Figure 1)*

a. The vias shall be located on 2.54 mm (0.10 inch) centers ± 0.076 mm (0.003 inches) non-accumulative.

b. The diameter of the vias shall be 1.143 mm (0.045 inches) ± 0.076 mm (0.003 inches).

c. The location of the vias on the board shall be as shown in Figure 1.

6.2.2.2 *Chip Carrier Packages (See Figure 2)*

a. The copper traces shall be laid out on the PC board as shown in Figure 2. The traces are drawn on 1.27 mm (0.050 inch) centers ± 0.127 mm (0.005 inch) non-accumulative.

b. The vias at the end of the copper traces shall be located on the 2.54 mm (0.10 inch) centers ± 0.076 mm (0.003 inch) non-accumulative.

6.2.2.3 *Quad Flat Packages (0.3, 0.4, 0.5, and 0.65 mm lead pitch) or sockets (see Figures 3 – 6)*

a. The copper traces shall be laid out on the PC board as shown in Figures 3 - 6. The traces are drawn in accordance with pitch and width as shown in Table 1.

Table 1 Trace Pitch and Width for QFP Package Boards

Package Lead Pitch (mm)	*Trace Pitch (mm)*	*Trace Width (mm)*
0.65	0.65 ± 0.05	0.35
0.5	0.5 ± 0.05	0.25
0.4	0.4 ± 0.04	0.2
0.3	0.3 ± 0.03	0.15

6.2.2.4 *Pin Grid Array Packages or Sockets (see Figure 7)*

a. The vias shall be located on 2.54 mm (0.10 inch) centers ± 0.076 mm (0.003 inches) non-accumulative.

b. The diameter of the copper lead shall be 1.2 mm ± 0.046 mm and the hole shall be 0.95 mm ± 0.046 mm.

c. The location of the vias on the board shall be as shown in Figure 7-1.

6.2.2.5 *Ball Grid Array Packages (1.5, 1.27, and 1.0 mm Ball Pitch) (see Figure 8)*

a. The copper traces shall be laid out on the PC board as shown in Figure 8-1. The traces and vias are drawn in accordance with configuration and dimension as shown in Table 2.

b. The board shall be covered by resist as shown in Figure 8-2. The back side of the board shall not be covered by resist.

Table 2 Trace Dimension for BGA Package Boards

Pad Pitch (mm)	*Trace Radius, R (mm)*	*Solder Mask Opening Diameter Ø1 (mm)*	*Hole Diameter Ø 2 (mm)*	*Number of Pads*
1.5	0.9	0.6	0.2	33 x 33
1.27	0.8	0.6	0.35	39 x 39
1.0	0.6	0.45	0.3	49 x 49

6.2.2.6 Equivalent boards for other packages should follow guidelines similar to those described in Sections 6.2.2.1 – 6.2.2.5.

6.2.2.7 *Multi-Layer Board* — When measuring thermal resistance using a multi-layer board, the layer shall be constructed as shown in Figure 9. The inner pattern should have the clearance as shown in Figure 10 to isolate with via holes.

6.3 *Mounting Guidelines*

6.3.1 Example of package mounting on the boards is shown in Figures 11 and 12. Packages should be mounted such that the center line of the test board is coincidental with the center line of the package.

6.3.2 For DIP and CCP, the longer edge of the package should be closest to the long edge of the board.

6.3.3 For QFP, PGA, and BGA package board, the package should be mounted in the center of the board.

6.3.4 Packages must be mounted such that the standoff height above the board is as per JEDEC guidelines. In the case of a new package without such information available, a minimum of 0.127 mm (5 mil) air gap between the bottom surface of the package and the thermal test board is acceptable.

6.4 *Mounting the Test Board for Still-Air $R_{\theta JA}$ Measurement*

6.4.1 The test board should be mounted on a clamp as shown in Figure 13 through a suitable edge connector clamp.

6.4.2 The test board and the edge connector clamp are placed in a 0.0283 m^3 (one cubic foot) enclosure as shown in Figure 13. The edge connector clamp height must be adjusted to ensure positioning of the package in the center of the chamber.

6.4.3 The electrical wire connections from the package are routed out of the one cubic foot enclosure either through an edge connector or through small diameter holes in the box.

6.5 *Mounting the Test Board for Forced-Air $R_{\theta JA}$ Measurement* — Forced air $R_{\theta JA}$ measurements are performed in a wind tunnel whose diameter is 203.2 mm (8.00 inches). Details of the wind tunnel are given in SEMI G38.

6.5.1 The test board should be mounted inside the wind tunnel on an edge connector clamp as shown in Figure 14.

6.5.2 The test board is placed in the wind tunnel such that the longer edge of the package is in a vertical position (see Figure 14).

6.5.3 The longer edge of the package should face the direction of air flow.

6.5.4 The longer side of the package must meet the air front first, as shown in Figure 14.

6.5.5 Air may be forced through the wind tunnel by either blowing from one end or by suction. (Suction being preferred.)

6.5.6 The test board and the edge connector clamp are placed in the wind tunnel as shown in Figure 14. The edge connector clamp height must be adjusted to ensure positioning of the package in the center of the wind tunnel.

6.6 *Thermal Resistance Measurement Methods* — Methods for measuring $R_{\theta JA}$ (Junction-to-Ambient Thermal Resistance) of IC packages using thermal test chips have been described in SEMI G32 and SEMI G38, respectively. These methods or equivalent methods such as the use of switching techniques, as described in MIL-STD-883C, Method 1021.1, should be used for making thermal resistance measurements of IC packages using thermal test chips or IC devices.

SEMI G43-87
TEST METHOD FOR JUNCTION-TO-CASE THERMAL RESISTANCE MEASUREMENTS OF MOLDED PLASTIC PACKAGES

1 Purpose

The purpose of this test is to determine the thermal resistance of molded plastic packages using thermal test chips. This test method deals only with junction-to-case measurements of thermal resistance and limits itself to fluid bath testing environments. For this test, conduction through the leads is minimized, thus providing information on the ability of the plastic package material to dissipate heat. Due to the thermophysical properties of the heat transfer fluids used and the effects of the variable nature of the fluid-stirring and package-mounting procedures, this test method should only be used for comparing the thermal characteristics of plastic packages in the same fluid bath system.

2 Applicable Documents

2.1 *SEMI Specification*

SEMI G32 — Guideline for Unencapsulated Thermal Test Chip

3 Definitions

The following definitions and symbols shall apply for the purpose of this test:

case temperature, T_C — in degrees Celsius. The case temperature is the temperature at a specified accessible reference point on the package in which the microelectronic chip is mounted.

junction temperature, T_J — in degrees Celsius. The term is used to denote the temperature of the semiconductor junction in the microcircuit in which the major part of the heat is generated. For purposes of this test, the measured junction temperature is only indicative of the temperature in the immediate vicinity of the element used to sense the temperature.

power dissipation, P_H — in watts, is the heating power applied to the device causing a junction-to-reference point temperature difference.

thermal resistance, junction to specified reference point, $R_{\theta JR}$ — in degrees Celsius/watt. The thermal resistance of the microcircuit is the temperature difference from the junction to some reference point on the package divided by the power dissipation P_H.

temperature-sensitive parameter, TSP — the temperature-dependent electrical characteristic of the junction under test which can be calibrated with respect to temperature and subsequently used to detect the junction temperature of interest.

4 Apparatus

The apparatus required for these tests shall include the following as applicable to the specified test procedures:

a. Thermocouple material shall be copper-constantan (type T) or equivalent, for the temperature range -100 to + 300°C. The wire size shall be no larger than AWG size 30. The junction of the thermocouple shall be welded to form a bead rather than soldered or twisted. The accuracy of the thermocouple and associated measuring system shall be ± 0.5°C.

b. Suitable electrical equipment as required to provide controlled levels of conditioning power and to make the specified measurements. The instrument used to electrically measure the temperature-sensitive parameter shall be capable of resolving a voltage change of 0.5 mV.

c. Controlled temperature chamber or fluid bath capable of maintaining the specified reference point temperature to within ± 0.5°C of the preset (measured) value. A typical temperature-controlled fluid bath assembly is presented for illustrative purposes only.

4.1 *Fluid Bath Assembly* — A typical temperature-controlled fluid bath for thermally characterizing the microelectronic device under test is shown in Figure 1. In this figure, the package is mounted in a fluid bath separate from the fluid circulator, although it can be immersed directly in an integrated fluid circulator/bath unit. The fluid in the bath should be continuously stirred or agitated to ensure the required temperature stability and uniformity. Since this working fluid is being used as an infinite heat-sink, the case-to-fluid (ambient) temperature difference at the case temperature reference point of interest should be minimized, i.e., ≤ 20°C. For case-to-fluid temperature differences > 20°C, accuracy and repeatability difficulties may occur due to a large variable temperature gradient in the fluid film boundary layer at the package-fluid interface. The case-to-fluid temperature difference can be minimized by increasing the fluid velocity and by decreasing the power density seen by the fluid.

The device under test should be mounted such that heat transfer to the fluid is not impeded. For leaded devices, the leads should be oriented in such a manner so as not to interfere with the heat transfer to the fluid and provide freedom to any thermal currents caused by the power dissipation within the package. The microcircuit package shall be mounted such that conduction cooling through the leads or test socket or both shall be small compared to the other cooling mechanisms. To minimize conduction through the leads, a special socket jig that connects No. 36 AWG wire to the device socket should be used.

The case temperature of the device under test should be measured with a thermocouple that is attached to the package/lead and should not be assumed to be at the fluid temperature. The working fluid should have a thermal conductivity at 25°C of at least 0.0006 W/cm°C. Working fluids such as inert fluorocarbon liquids and silicone oils are suitable as cooling media.

5 Procedure

5.1 *Direct Measurement of Reference Point Temperature,* $T_R = T_c$ — For the purpose of measuring a microelectronic device thermal resistance, the reference point temperature shall be measured at the package location of highest temperature which is accessible from outside the package. This reference point location is determined with the device operating in free air and with no external heat-sinking. In general, this reference point is found to be on the surface of the body of the package, or on a lead near the body, in the major path of heat flow from the chip heating surface to the ambient fluid. The package surface may be altered to facilitate this measurement provided that such alteration does not affect the original heat transfer paths and, hence, the thermal resistance, within the package by more than a few percent.

5.1.1 *Case Temperature,* T_c — The microelectronic device under test shall be mounted under specified conditions so that the case temperature can be held at the specified value. A thermocouple shall be attached on the surface of the device package directly under the chip (i.e., on the base plane of the package). A conducting epoxy may be used for this purpose. The thermocouple bead should be in direct mechanical contact with the package of the microelectronic device under test. Care should be taken to minimize exposure of the thermocouple bead to the high temperature gradient in the fluid film boundary layer at the package-fluid interface.

If it is found that attaching the thermocouple directly to the case is impractical, an alternate approach using a thermocouple welded to one side of a thin metal disk should be used. This can be accomplished by parallel gap welding the crossed thermocouple wires to one side of a 0.25 cm (0.094 in) diameter, 0.02 cm (0.008 in) thick beryllium-copper disk and then, with a thin layer of adhesive, bonding the other side of the disk to the case at the point of interest. The exposed thermocouple bead/wire on the disk shall be covered with epoxy or silicone rubber. The attached thermocouple should not unduly interfere with heat transfer to the fluid.

5.2 *Thermal Resistance, Junction-to-Specified Reference Point,* $R_{\theta JR}$

5.2.1 *General Considerations* — The thermal resistance of a semiconductor device is a measure of the ability of its carrier or package and mounting technique to provide for heat removal from the semiconductor junction. The thermal resistance of a microelectronic device can be calculated when the case temperature and power dissipation in the device and a measurement of the junction temperature are known.

When making the indicated measurements, the package shall be considered to have achieved thermal equilibrium when halving the time between the application of power and the taking of the reading causes no error in the indicated results within the required accuracy of measurement.

5.2.2 *Indirect Measurement of Junction Temperature for the Determination of* $R_{\theta JR}$ — The purpose of the test is to measure the thermal resistance of integrated circuits by using particular semiconductor elements on the chip to indicate the device junction temperature. In order to obtain a realistic estimate of the operating junction temperature, the whole chip in the package should be powered in order to provide the proper internal temperature distribution. During measurement of the junction temperature, the chip heating power (constant voltage source) shall remain constant while the junction calibration current remains stable. It is assumed that the calibration current will not be affected by the circuit operation during the application of heating power.

The temperature-sensitive device parameter is used as an indicator of an average (weighted) junction temperature of the semiconductor element for calculations of thermal resistance. The measured junction temperature is indicative of the temperature only in the immediate vicinity of the element used to sense the temperature.

The temperature-sensitive electrical parameters generally used to indirectly measure the junction temperature are the forward voltage of diodes and the emitter-base voltage of bipolar transistors. Other appropriate temperature-sensitive parameters may be used for indirectly measuring junction temperature for fabrication technologies that do not lend themselves to sensing the active junction voltages.

5.2.2.1 *Steady-State Technique for Measuring* T_J — The following symbols shall apply for the purpose of these measurements:

I_M — ring current in milliamperes.

V_{MH} — Value of temperature-sensitive parameters in millivolts, measured at I_M, and corresponding to the temperature of the junction heated by P_H.

T_{MC} — Calibration temperature in degrees Celsius, measured at the reference point.

V_{MC} — Value of temperature-sensitive parameter in millivolts, measured at I_M and specific value of T_{MC}.

The measurement of T_J using junction forward voltage as the TSP is made in the following manner:

Step 1 — Measurement of the temperature coefficient of the TSP (calibration).

The coefficient of the temperature-sensitive parameter is generated by measuring the TSP as a function of the reference point temperature, for a specified constant measuring current, I_M, by externally heating the device under test in an oven or in a fluid bath. The reference point temperature range used during calibration shall encompass the temperature range encountered in the power application test (see Step 2). The measuring current is generally chosen such that the TSP decreases linearly with increasing temperature over the range of interest and that negligible internal heating occurs in the silicon and metal traces. For determining the optimum TSP calibration or measuring current, V_{MC} vs. log I_M curves for two temperature levels that encompass the calibration temperature range of interest should be plotted. The optimum measuring current, I_M, is then selected such that it resides on the linear portion of the two V_{MC} vs. log I_M curves that were generated. A measuring current ranging from 0.05 to 5 mA is generally used, depending on the specifications and operating conditions of the device under test, for measuring the TSP. The value of the TSP temperature coefficient V_{MC}/T_{MC}, for the particular measuring current used in the test, is calculated from the calibration curve, V_{MC} vs. T_{MC}. At least three points should be used to generate the voltage vs. temperature curve for the determination of the TSP temperature coefficient.

Step 2 — Power application test.

The power application test is performed in two parts. For both portions of the test, the reference point temperature is held constant at a preset value. The first measurement to be made is that of the temperature-sensitive parameter, i.e., V_{MC}, under operating conditions with the measuring current, I_M, used during the calibration procedure. The microelectronic device under test shall then be operated with heating power (P_H) applied. The temperature-sensitive parameter, V_{MH}, shall be measured with constant measuring current, I_M, that was applied during the calibration procedure (see Step 1).

The heating power, P_H, shall be chosen such that the calculated junction-to-reference point temperature difference as measured at V_{MH} is $\geq$ 20°C. In accomplishing this, the device under test should not be operated at such a high heating power level that the on-chip temperature-sensing and heating circuitry is no longer electrically isolated. Care should also be taken not to exceed the design ratings of the package-interconnect system, as this may lead to an overestimation of the power being dissipated in the active area of the chip due to excessive power losses in the package leads and wire bonds. The values of V_{MH}, V_{MC}, and P_H are recorded during the power application test.

The following data shall be recorded for these test conditions:

a. Temperature-sensitive electrical parameters (V_F, V_{EB}, or other appropriate TSP).

b. Junction temperature, T_J, is calculated from the equation:

$$T_J = T_R + \left(V_{MH} - V_{MC}\right)\left|\frac{\Delta V_{MC}}{\Delta T_{MC}}\right|^{-1}$$

where $T_R = T_C$

c. Case temperature, T_C (including specific location).

d. Power dissipation, P_H.

e. Mounting arrangement (including method of thermocouple attachment and fluid temperature).

5.3 *Calculations of* $R_{\theta JR}$

5.3.1 *Calculations of Package Thermal Resistance* — The thermal resistance of a microelectronic device can be calculated when the junction temperature, T_J, has been measured in accordance with procedures outlined in Sections 5.1 and 5.2.

With the data recorded from each test, the thermal resistance shall be determined from:

$$R_{\Theta JR} = \frac{T_J - T_R}{P_{H(Package)}} \quad \text{junction-to-reference point}$$

where

$R_{\Theta JR} = R_{\Theta JA}$ and $T_R = T_A$.

6 Summary Report

The following details shall be specified as appropriate:

a. Description of package; including thermal test chip, location of case or chip carrier temperature measurement(s), and mounting arrangement.

b. Test condition(s), as applicable (see Section 5).

c. Test voltage(s), current(s), and power dissipation of test chip.

d. Recorded data for each test condition, as applicable.

e. Symbol(s) with subscript designation(s) of the thermal characteristics determined.

f. Accept or reject criteria.

SEMI G44-94
SPECIFICATION FOR LEAD FINISHES FOR GLASS TO METAL SEAL CERAMIC PACKAGES (ACTIVE DEVICES ONLY)

1 Preface

1.1 This specification defines lead finishes for glass to metal seal ceramic packages assembled with iron-nickel alloy leadframe construction. It defines composition, properties, limits, and refers to appropriate tests for utility.

1.2 *Scope* — The criteria detailed in this document applies to glass to metal seal ceramic packages, assembled with iron-nickel alloy leadframe construction, which conforms to composition limits specified in MIL-M-38510 as lead material Type A or Type B.

1.3 *Units* — U.S. Customary (inch-pound) or metric (SI) units may be used at the customer's discretion. This specification uses U.S. Customary units as the prime unit.

2 Applicable Documents

2.1 *Order of Precedence* — To avoid conflicts, the order of precedence when ordering packages shall be as follows:

Purchase Order
Customer Package Drawing
This Specification
Reference Documents
Related Documents

2.1.1 *SEMI Specifications*

SEMI G2 — Specification; Metallic Leadframes for Cer-DIP Packages

SEMI G35 — Specification; Test Methods for Lead Finishes on Semiconductor (Active Devices)

2.1.2 *ASTM Specifications*[1]

B 487 — Measuring Metal and Oxide Coating Thickness by Microscopical Examination of a Cross Section

B 545 — Standard Specification for Electro-deposited Coatings of Tin

B 567 — Measurement of Coating Thickness by the Beta Backscatter Principle

B 568 — Measurement for Coating Thickness by X-Ray Spectrometry

B 571 — Adhesion of Metallic Coatings

E 384 — Standard Test Methods for Micro-hardness of Materials

2.1.3 *Federal Specification*[2]

QQ-S-571 — Solder, Tin Alloy; Tin-Lead Alloy; and Lead (Pb) Alloy

2.2 *Military Specifications*[2]

MIL-T-10727 — Tin Plating; Electrodeposits or Hot Dipped, for Ferrous and Non-Ferrous Metals

MIL-G-45204 — Gold Plating, Electrodeposited

MIL-STD-883 — Test Methods and Procedures for Microelectronics

MIL-M-38510 — Microcircuits, General Specification

3 Terminology

blister — An enclosed localized separation of the plating from its base metal or an underplated layer that does not expose the underlying layer.

pit — A shallow depression or crater. The bottom of the depression must be visible.

solder — As used in this specification, refers to tin lead (Pb) as 63/37 or 60/40, unless otherwise specified and agreed upon between user and supplier and stated on procurement drawings.

4 Dimensions and Material

Composition limits, mechanical and physical properties, dimensions and tolerances for Cer-DIP leadframes are as stated in SEMI G2.

Table 1 lists recommended finishes for devices employing iron nickel alloy leadframe (MIL-M-38510 Lead Material Type A or Type B).

Gold plate is useable in socketed applications as well as in soldered applications. Hardness, grain size, and other properties shall be specified in the procurement drawing.

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohoken, PA 19428-2959

2 Military Standards, Naval Publications and Form Center, 5801 Tabor Avenue, Philadelphia, PA 19120

5 Lead Finish Requirements

5.1 *Tin Electroplate*

5.1.1 *Composition* — The tin deposit shall not be less than 99.8% pure tin and shall not contain more than 0.05% pure carbon. The deposit is Type 1 as defined in MIL-T-10727.

5.1.2 *Characteristics* — The procedure used for evaluating the tin coating and the general requirements for the coating shall comply with ASTM B 545 or the latest current revision, except where noted below.

5.1.2.1 *Thickness* — The plated coating as measured on the major flat of the leads shall be a minimum of 300 microinches (7.5 micrometers).

5.1.2.2 *Appearance* — Surface appearance shall be smooth, fine grained, adherent and free from exposed basis metal or underplate, visible blisters, pits, nodules, porosity, indications of burning, excessive edge buildup and other detrimental defects.

5.1.2.3 *Hardness* — None specified.

5.1.2.4 *Preservation* — Preservation coating, if desired and agreed upon by user and supplier, is acceptable. (Example: Stearic acid solution in xylol as defined in MIL-T-10727.)

5.2 *Tin Lead (SnPb) Electroplate*

5.2.1 *Composition* — Major constituents shall be tin and lead (Pb) with minor impurities. Range of major constituents shall be:

Tin	50%-98%
Lead (Pb)	2%-50%
Nominal	60% Tin, 40% Lead (Pb)

NOTE: Users should be advised that many plating solutions containing lead (Pb) also contain acid fluorides. Such solutions will attack those glass materials commonly used in ceramic packages. Adequate process controls must be developed and used in conjunction with this plating process to ensure package and device integrity.

5.2.2 *Purity and Application* — Per MIL-M-38510.

5.2.3 *Thickness* — Shall be a minimum of 7.5 micrometers (300 microinches) as measured on the major flat of the leads.

5.2.4 *Appearance* — Surface appearance shall be smooth, fine-grained, adherent, and free from exposed basis metal or underplate, visible blisters, pits, nodules, porosity, indications of burning, excessive edge buildup and other detrimental defects.

5.2.5 *Hardness* — None specified.

5.3 *Tin/Lead (Pb) Solder-Dip*

5.3.1 Solder Pot Composition and Purity — Sn60 or Sn63, per QQ-S-571.

5.3.2 Thickness — Shall be a minimum of 5 micrometers (200 microinches) as measured on the major flat of the leads.

5.3.3 Process Conformance — Solder coating is applicable as shown in Table 1. In addition, the coating is acceptable as follows:

1. Over the electroplated tin or tin/lead as per Section 4.1 or 4.2.
2. Over the electroplated gold as per Section 4.4.

5.3.4 *Appearance* — Surface shall be smooth and continuous.

5.3.5 *Hardness* — None specified.

5.3.6 *Coverage* — Electroplated packages.

5.3.6.1 The solder dip shall extend up to and beyond the effective seating plane for Cer-DIPs.

5.3.6.2 The solder dip shall extend within .030" from glass seal for Cer-Packs.

5.3.7 *Coverage* — Non-coated packages.

5.3.7.1 When applied over the base metal, hot solder dip shall cover the entire lead to the glass seal or point of emergence of the lead or metallized contact through the package wall.

5.4 *Gold Electroplate*

5.4.1 *Composition* — Gold plating shall be applied in accordance with MIL-G-45204 in any and all of the following grades depending on application.

Type I	99.7% minimum
Type II	99.0% minimum
Type III	99.9% minimum

NOTE: Type II is suitable for socketing application only.

5.4.2 *Thickness* — Shall be 1.27–5.72 micrometers (50-225 microinches) as measured on the major flat of the leads per MIL-M-38510.

5.4.3 *Appearance* — Surface appearance shall be smooth, fine-grained, adherent and free from exposed basis metal or underplate, visible blisters, pits, nodules, porosity, indications of burning, excessive edge buildup, and other detrimental defects.

5.4.4 *Purity* — Composition limits are as specified in Section 4.4.1 above. Individual metallics in the deposit shall not exceed 0.1%. Metallic hardening agents, purposely added to adjust a plating bath to specified hardness are not considered as impurities.

5.4.5 *Hardness* — Depending on type and application, hardness is specified, using Knoop indenter in the following categories (testing is done as per ASTM E 384):

Type	*Grade*	*Hardness (Knoop)*
I	A	90 max
	B	91-129
	C	130-200
II	B	91-129
	C	130-200
	D	201 and over
III	A	90 max

5.5 *Reflowed Plated Tin or Plated Tin/Lead*

5.5.1 *Composition* — As per the plated finish, Section 4.1.2 or 4.2.1, as applicable.

5.5.2 *Characteristics* — As per 4.1.2 and 4.2, as applicable.

5.5.3 *Thickness* — The thickness of such reflowed coatings must be a minimum of 200 microinches measured on a significant surface.

5.5.4 *Appearance* — The appearance of reflowed coatings must be smooth and continuous.

Table 1 Recommended Finishes

Finish	*Mil Spec*	*Over Base Metal*	*Undercoating*			
			Ni	*Sn*	*SnPb*	*Au*
Tin	MIL-T-10727	X	X			
TinLead (SnPB)	MIL-M-38510	X	X			
Electroplate Solder	QQ-S-571	X	X	X	X	X
DIP(SnpB) Gold	MIL-G-45204	X	X*			

*Ni undercoat required by MIL-M-38510.

6 Test Methods

Tests for the lead finishes shall be in accordance with SEMI G35.

7 Sampling

The sampling plan, based on MIL-STD-105 shall be agreed between vendor and customer.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. SEMI G45-93
RECOMMENDED PRACTICE FOR FLASH CHARACTERISTICS OF THERMOSETTING MOLDING COMPOUNDS

1 Scope

This method describes a procedure for measuring the flashing characteristics of semiconductor grade transfer molding compounds.

2 Significance

2.1 The flashing tendency for semiconductor grade molding compounds depends on the interaction of several variables, including mold conditions, process parameters, molding compound viscosity, and curing characteristics. This test is not a valid method for predicting the flashing performance in all mold types. It is a method for comparing flash tendency and flashing type of different molding compounds when evaluated under a specific set of molding process parameters.

2.2 Flashing presents problems with subsequent processing of plastic packaged devices after molding. A high flashing tendency increases die wear in the trim and form operation, may interfere with plating or solder dip finishing operations, and may prevent good contact for electrical test. Thus, reduced tendency toward flashing will improve the plastic package subassembly operations. The information from this test will be of value in rating flash performance of any given compound to that in production use.

3 Apparatus

3.1 Transfer molding press with a platen area sufficient to maintain a uniform mold temperature and having (1) a transfer piston pressure potential of 1000 psi on the material; (2) sufficient clamping pressure to prevent flashing of the molding compound at clamping lands; and (3) a minimum plunger speed of 25.4 mm (1 inch) per second without load. The pot diameter shall be 31.75 to 44.45 ± 0.735 mm (1.250 to 1.750 ± 0.025 inch) and the clearance between pot and ram shall be sufficiently small that flashing does not occur above the first sealing groove on the ram.

3.2 *Standard Flash Test Mold* — Per Figure 1.

3.3 *Force Gauge* — With appropriate range to calibrate transfer pressure to minimum of 10.343 mpa (1,500 psi).

3.4 *Steel Rule* — Measured in 0.25 mm (0.010 in).

3.5 *Halo Lamp* — 3× magnification, minimum.

3.6 *Thermocouple and/or Pyrometer Calibrated* — In the 160°–190°C range (calibration to be checked every 6 months).

4 Test Conditions

4.1 *Molding Compounds* — Refrigerated shipment and storage of some molding compounds is necessary. The molding compound is to be at room temperature before the container is opened. Care must be taken to preserve the original moisture content. The material should be in powdered form, unless otherwise specified.

4.2 *Flash Test Mold* — Shall be clean and free from any mold release agents or lubricants. A standard mold cleaning compound can be used to insure mold cleanliness.

4.3 *Molding Conditions*

4.3.1 The temperature of the mold shall be measured using a thermocouple inserted in the mold or with a surface pyrometer. The ram shall be kept at the mold temperature. Molding temperature is to be 175°C unless otherwise specified. Temperature must be maintained within ± 3°C (± 5°F) of the specified temperature.

4.3.2 The transfer pressure for test, as measured under the transfer plunger, is to be 6.895 ± 0.177 mpa (1000 ± 25 psi) unless otherwise specified.

4.3.3 The weight of the charge shall be adjusted to give a molded cull thickness of 3.303 ± 0.254 mm (0.130 ± 0.010") excluding vertical flash.

4.3.4 The free running ram speed shall be at least 25.4 mm/sec (1"/sec). Recommended speed is 100 ± 25 mm/sec into the pot and application of pressure on the charge shall be maintained throughout the mold cycle.

4.3.5 Unless otherwise specified, a minimum of 1.5 minutes close and cure time shall be used.

4.3.6 Flash length shall be measured in 0.25 mm (0.010 in) intervals.

5 Procedure

5.1 Thoroughly clean the ram, pot, and mold of any cured compound, or other foreign matter.

5.2 Heat the mold and ram to within ± 3°C of the specified temperature.

5.3 At the beginning of each series of tests and at each change of compound, check and set the transfer pressure using the force gauge. The proper force gauge setting can be determined from the formula:

$$F = \frac{\Pi D^2 P}{4}$$

where F is the force in pounds, P is the desired pressure on the material in psi, and D is the ram diameter in inches.

5.4 For each material change, make at least three clean out runs using the material to be tested before recording data. These runs may be used to determine the charge weight.

5.5 Weigh out the compound to the nearest 0.1 g as previously determined to yield a cull of 3.302 ± 0.254 mm (0.130 ± 0.010 in).

5.6 Raise the ram, add the compound to the pot, and immediately activate the transfer cycle.

5.7 Remove cull and measure thickness. If the cull is not within 0.130 ± 0.010 in, discard the run and repeat the test, adjusting the charge weight as necessary.

5.8 Open mold and measure longest flash for each channel to nearest 0.25 mm (0.010 in) using 3× minimum magnification. Be sure to check both top and bottom plates of mold before measuring flash.

NOTE: Care must be taken to include the measurement of transparent and semi-transparent flash which may be present in the smaller channel. After measurements, diligence is required to remove all flash, including the transparent and semi-transparent varieties prior to the next test.

5.9 Repeat Steps 5.6 through 5.8 at least 3 times for repeatability.

6 Reporting of Results

6.1 Report the material designation and lot number.

6.2 Report the average and standard deviation of the flash length in each channel.

6.3 Report the temperature and pressure used for the tests.

NOTE: Common Errors/Problems:

- Inadequate preheat of flash mold and/or transfer plunger prior to test and between shots.
- Incorrect cull thickness.
- Omission of transparent or semi-transparent flash in measurement (often present in smallest two channels).
- Inadequate cleaning of mold between shots.
- Starting from the end of the ruler to make flash length measurements instead of starting at a known distance from the end.
- Inadequate mold break-in. Three shots should be run and disregarded before recording flash measurements for each material.
- Sprue, channel entry point, and mating mold surface wear may produce error in measurement and correlation problem. The impact of wear on results has not been determined. Extent of permissible mold wear requires agreement between testing organizations.

SEMI G46-88

TEST METHOD FOR THERMAL TRANSIENT TESTING FOR DIE ATTACHMENT EVALUATION OF INTEGRATED CIRCUITS

1 Introduction

1.1 *Purpose* — Evaluation of semiconductor die attachment integrity using the thermal transient techniques as implemented by the Electrical Test Method on either thermal test chips or active devices.

1.2 *Rationale* — Steady state thermal response (or thermal resistance) and thermal transient response of discrete semiconductor devices and integrated circuits are sensitive to the presence of voids in the die attachment material between the semiconductor chip and package. These voids impede the flow of heat from the chip to the substrate (package). Due to the difference in the thermal time constants of the chip and package, the measurement of transient thermal response can be made more sensitive to the presence of voids than can the measurement of steady state thermal response. This is because the chip thermal time constant is generally several orders of magnitude shorter than that of the package. Thus, the heating power pulse width can be selected so that only the chip and the chip to substrate interface are heated during the pulse by using a pulse width somewhat greater than the chip thermal time constant, but less than that of the substrate. Heating power pulse widths ranging from 10 to 400 milliseconds have been found to satisfy this criterion. This enables the detection of voids to be greatly enhanced, with the added advantage of not having to heat sink the device under test. Thus, the transient thermal response technique is less time consuming than the measurement of thermal resistance for use as a manufacturing screen, process control or incoming inspection measure for die attachment integrity evaluation.

1.3 *References* — The following documents are recommended reading for reference and test method standard description purposes:

SEMI G32 — Unencapsulated Thermal Test Chip

MIL-STD-883C[1] — Method 1012, Thermal Characteristics

2 Definitions

The following symbols and terminology shall apply for the purpose of this test method.

2.1 V_F — the forward biased voltage of the diode junction within the Device-Under-Test (DUT) used for junction temperature sensing.

2.2 V_{Fi} — the initial V_F value before application of heating power.

2.3 V_{Ff} — the final V_F value after application of heating power.

2.4 ΔV_F — the change in the temperature sensitive parameter, V_F, due to the application of heating power to the DUT.

2.5 V_H — the voltage applied to the DUT during the heating time in order to cause power dissipation.

2.6 I_H — the heating current resulting from the application of V_H to the DUT.

2.7 P_H — the heating power pulse magnitude; product of V_H and I_H.

2.8 t_H — the duration of P_H (applied to the DUT).

2.9 I_M — the measurement current used to forward bias the temperature sensing diode junction for measurement of V_F.

2.10 t_{MD} — measurement delay time can be defined in one of two ways:

2.10.1 the time from the start of heating power (P_H) removal to the completion of the final V_F measurement; or

2.10.2 the time from the start of heating power (P_H) removal to the start of the final V_F measurement time, referred to as t_{SW}.

2.11 t_{SW} — sample window time during which final VF measurement is made; applicable only if t_{MD} definition 2.10.2 is used.

2.12 *K* — the temperature-sensitive parameter temperature coefficient measured at IM in °C per millivolt.

2.13 *CU* — the comparison unit consisting of ΔV_F divided by I_H, that is used to normalize the transient thermal response for variations in power dissipation; in units of mV/A.

2.14 T_J — the device-under-test junction temperature.

2.15 ΔT_J — the change in T_J caused by the application of P_H for a time equal to t_H.

1 Military Standards, Naval Publications and Form Center, 5801 Tabor Avenue, Philadelphia, PA 19120

2.16 σ_Δ — the standard deviation if the ΔV_F results for a given test condition.

2.17 σ_{CU} — the standard deviation of the CU results for a given test condition.

3 Test Operation

The following paragraphs describe in conceptual detail the operation of the test for integrated circuit thermal response.

3.1 *Set-Up* — Shown in Figure 1 is the set-up required for testing either active devices or thermal test chips. Figure 1a is used for those cases in which the TSP is the junction isolation diode forward biased voltage. Thermal test chips and test IC's for which the junction isolation diode is either not available, or desirable for temperature sensing, can be handled by the set-up shown in Figure 1b.

3.2 *Apparatus* — To implement either version of Figure 1 requires the following apparatus:

3.2.1 A constant voltage source capable of adjustment to the desired value of V_H and able to supply the I_H value drawn by the DUT.

3.2.2 A constant current source to supply I_M with sufficient voltage compliance to turn the TSP junction fully on.

3.2.3 An electronic switch capable of switching between the heating period conditions and measurement conditions in a time frame short enough to avoid DUT cooling during the transition; this typically requires switching in the microsecond range.

3.2.4 A voltage measurement circuit capable of accurately making the V_H measurement within the t_{MD} (or t_{MD} plus t_{SW}, depending on the definitions stated previously) time frame with millivolt resolution.

3.3 *Operation and Waveforms* — The test begins with the adjustment of I_M and V_H to the desired values. Then with the electronic switch in position 1, the value of V_F is measured. The switch is then moved to position 2 for a length of time equal to t_H and the value of I_H is measured. Finally, at the conclusion of t_H, the switch is again moved to position 1 and the V_F value is measured within a time period defined by t_{MD} (or t_{MD} plus t_{SW}, depending on the definitions stated previously). The voltage and current sources are then turned off at the completion of the test.

The voltage and current waveforms for the two versions of Figure 1 are shown in Figure 2.

4 Test Procedure

The procedures below describe how to set up the test conditions and determine the acceptance limits for implementing the transient thermal test for die attachment evaluation using the apparatus and definitions stated above.

4.1 *Initial Device Testing Procedure* — The following steps describe in detail how to set up the apparatus described previously for proper testing of various integrated circuit devices.

Step 1 — From a 10 to 15 piece sample of the integrated circuits to be tested, pick any one device to start the set-up process. Set up the test apparatus as follows:

V_H = 5.0 V (Or some other desired value near the device under tests (DUT's) normal operating voltage.)

t_H = 200 ms

t_{MD} = 15 us

I_M = 1.0 mA (Or some other value appropriate for the specific device under test; typically in the range of 80 uA to 9.9 mA.)

Step 2 — Insert device into the apparatus test fixture and initiate a test.

(For best results, a test fixture that offers some form of heat sinking would be desirable.)

Step 3 — If ΔV_F is in the 20 to 40 mV range, then proceed to the next step. This range corresponds to a junction temperature change of roughly 10°C to 20°C and is sufficient for initial comparison purposes.

If ΔV_F is less than 20 mV, return to Step 1 and increase heating power into device by increasing V_H, or by reconfiguring the DUT connections for greater power dissipation, or a combination of both.

If ΔV_F is greater than 80 mV, corresponding to a junction temperature change greater than 40°C, it would probably be desirable to reduce the heating power by returning to Step 1 and reducing V_H, or by reconfiguring the DUT connections to reduce power dissipation, or a combination of the two. Reducing V_H is the preferable approach.

Because two different devices can show the same rise in junction temperature, even if the value of P_H is different, a comparison of the devices is best accomplished using the CU value. As defined in Section 2 above, CU provides a comparison unit that takes into account different device I_H values for a given V_H test condition.

Step 4 — Test each of the sample devices and record the ΔV_F and CU data as shown in Figure 3.

Step 5 — Select out the devices with the highest and lowest values of CU and put the remaining devices aside.

The ΔV_F values can be used instead of CU if the measured values of I_H are very tightly grouped aroung the average value.

Step 6 — Following the Heating Time (t_H) sequence shown in Figure 4, read and record the ΔV_F and CU data values for each of the two devices of Step 5.

Step 7 — Using the data from the previous step, prepare heating curves for the two devices in a manner similar to the examples shown in Figure 5.

Step 8 — Interpretation of the heating curves is the next step. Realizing that the thermal characteristics of identical chips should be the same if the heating time (t_H) is less than or equal to the thermal time constant of the chip, the two curves should start out the same for the low values of t_H. Non-identical chips (i.e., thinner or smaller in cross section) will have completely different curves, even at the smaller values of t_H. As the value of t_H is increased, thereby overcoming the chip thermal constant, heat will have propagated through the chip into the die attachment region. Since the heating curve devices of Step 5 were specifically chosen for their difference, the curves of Figure 5 diverge after t_H reaches a value where the die attachment variance has an effect on the device junction temperature. Increasing t_H further will probably result in a flattening of the curve as the heating propagates in the device package. If the device package has little thermal mass and/or is not well mounted to a good heat sink, the curve will not flatten very much, but will show a definite change in slope. Figure 6 shows the key elements of the heating curve.

Step 9 — Using the heating curve, select the appropriate value of t_H to correspond to the inflection point in the transition region between heat in the chip and heat in the package.

If there are several different elements in the heat flow path-chip, die attachment, substrate, substrate attachment, and package, for example, in a hybrid there will be several plateaus and transitions in the heating curve. Appropriate selection of t_H will optimize evaluation sensitivity to other attachment areas.

Step 10 — Return to the apparatus and set t_H equal to the value determined from Step 9.

Step 11 — Because the selected value of t_H is much less than that for thermal equilibrium, it is possible to significantly increase the heating power without degrading or destroying the device. The increased power dissipation within the device under test will result in high ΔV_F and/or CU values that will make determination of acceptable and non-acceptable devices much easier.

Step 12 — The pass/fail limit, the cutoff point between acceptable and non-acceptable devices, can be established in a variety of ways:

a) Correlation to other die attachment evaluation methods, such as die shear and/or x-ray; while these two methods have little actual value from a thermal point of view, they do represent standardized methods as described in MIL-STD specifications.

b) Maximum allowable junction temperature variation between devices; since the relationship between ΔT_J and ΔV_F is about 0.5°C/mV, the junction temperature spread between devicescan be easily determined. The T_J predicts reliability. Conversely, the T_J spread necessary to meet the reliability projections can be translated to a ΔV_F and/or CU value for a Pass/Fail criteria, based on correlation with steady-state thermal equilibrium conditions.

To fully use this approach, it will be necessary to calibrate the devices for the exact value of the T_J - V_F characteristic. The characteristic's slope, commonly referred to as K Factor, is easily measured on a sample basis using a voltmeter, environmental chamber, temperature indicator and a power supply setup for forcing, both active devices and thermal test chips as shown in Figure 7. A simple set of equations yields the junction temperature once K and ΔV_F are known:

$$\Delta T_j = | (K) (\Delta V_F) |$$

$$T_J = T_A + \Delta T_j$$

Where T_A is the ambient or reference temperature.

c) Statistically from a moderate size device sample; the distribution of ΔV_F or CU values should be a normal one with defective devices out of the normal range. Figure 8 shows a ΔV_F distribution for a sample lot of integrated ciruits. Note that the left-hand side of the histogram envelope is fairly well-defined, but the other side is greatly skewed to the right. This comes about because the left-hand side is constrained by the absolutely best heat flow that can be obtained with a given chip assembly material and process. The other side has no such constraints because there is no limit as to how poorly a chip is mounted.

The usual rule of thumb in setting the maximum limit for ΔV_F or CU is to use the distribution average value and one standard deviation (σ) i.e. —

$$\left.(\Delta V_F)\right|_{\text{high limit}} = \overline{\Delta V_F} + X\sigma_{\Delta}$$

$$\left.(CU)\right|_{\text{high limit}} = \overline{CU} + X\sigma_{CU}$$

Where X = 1 in most cases.

The statistical data required is obtained by testing 40 or more devices under the conditions of Step 11.

Step 13 — Once the test conditions and pass/fail limit have been determined, it is necessary only to record this information for future testing requirements of the same device in the same package. With the apparatus properly set-up, including the fail limit selector on those apparatus set ups so equipped, the operator need only insert the device, initiate a test, and then either read the ΔV_F or CU display or observe the appropriate pass or fail indicaors.

The steps listed hereto have been conveniently summarized in Figure 9. The total time required to perform these steps is greatly dependent on the operator but, in general, should require about one hour if the statistical approach of Step 12.C is used.

4.2 *Routine Device Testing Procedure* — Once the proper control settings have been determined for a particular device type from a given manufacturing process or vendor, repeated testing of that device type simply requires that the same test conditions be used as previously determined.

New device types or the same devices manufactured with a different process will require a repeat of Section 4.1.

4.3 *Comparison of Different Vendor Devices* — Each device type is defined as a specific chip manufactured to a given set of procedures. Integrated circuit users who buy a specific part number from more than one vendor or manufacturers that redesign or otherwise modify the fabrication of their devices will be able to use the heating power and approximately the same t_H for all vendors, but probably will have to use a different ΔV_F or CU pass/fail limit for each different vendor because the K Factor for parts manufactured by different vendors will probably be different. The difference can be determined in Step 12.B and using the setup described in Figure 7.

5 Test Condition Specification

To properly set up the test apparatus and to insure repeatable measurements, the following test conditions must be fully specified:

a. V_H

b. t_H

c. I_M

d. t_{MD} (and t_{SW} if appropriate)

e. DUT/apparatus interface (i.e., wiring connection)

f. ΔV_H or CU data requirement

$T_H = 400$ ms

$I_M = 1.0$ mA

$t_{MD} = 20$

$\overline{CU} = 249$ mV/A

$\sigma_{cu} = 53.5$ mV/A

CU = 302.5 mV/A

high limit

Figure 8

CU bar graph shows thermal distribution of 50 devices when tested at a heating time of 400 ms. (Note: CU data rounded off to nearest m V/A.)

	General Description	*Steps*	*Comments*
A	Initial Setup	1 thru 4	Approximate instrument settings to find variations among devices in 10 to 15 piece sample.
B	Heating Curve Generation	5 thru 7	Using highest and lowest reading devices, generate Heating Curves.
C	Heating Curve Interpretation	8 thru 10	Heating Curve is used to find more appropriate value for t_H corresponding to heat in the die attachment are (or some other desired interface in the heat flow path).
D	Final Setup	11	Heating Power applied during t_H is increased in order to improve measurement sensitivity to variations among devices.
E	Pass/F Determination	12 thru 13	A variety of methods is available for setting the fail limit; the statistical approach is the fastest and easiest to implement.

Figure 9 — Summary table of steps required to implement thermal transient testing for IC die attachment evaluation.

SEMI G47-88
SPECIFICATION FOR PLASTIC MOLDED QUAD FLAT PACK LEADFRAMES

1 Preface

This specification defines the acceptance criteria for leadframes designed for assembly of JEDEC registered publication 95 standard outlines for "Plastic Quad Flat Pack 0.025" lead spacing (gull wing) packages". It is a design guideline for packaging engineers, leadframe stampers and etchers, mold and trim/form tooling manufacturers. It has been developed to meet the requirements of assemblers using automatic and manual equipment.

2 Applicable Documents

2.1 *SEMI Specifications*

SEMI G4 — Specification, Integated Circuit Leadfame Materials in the Production of Stamped Frames

SEMI G18 — Specification, Integrated Circuit Leadframe Materials Used in the Production of Etched Frames

SEMI G10 — Standard Method, Mechanical Measurement for Plastic Package Leadframes

SEMI G21 — Specification, Plating Integrated Circuit Leadframes

2.2 *ANSI Specification*[1]

Y 14.5M-1982 — Dimensioning and Tolerancing

2.3 *JEDEC Specification*[2]

Registration 95 — Plastic Quad Flat Pack, 0.025" Lead Spacing (Gull Wing)

2.4 *Military Specification*[3]

MIL-STD-105 — Sampling Procedures and Tables for Inspection by Attributes

3 Selected Definitions

burr — a fragment of excess material either horizontal or vertical attached to the leadframe.

camber — curvature of the leadframe strip edge (see Figure 1).

coil set — Longitudinal bowing of the leadframe (see Figure 2).

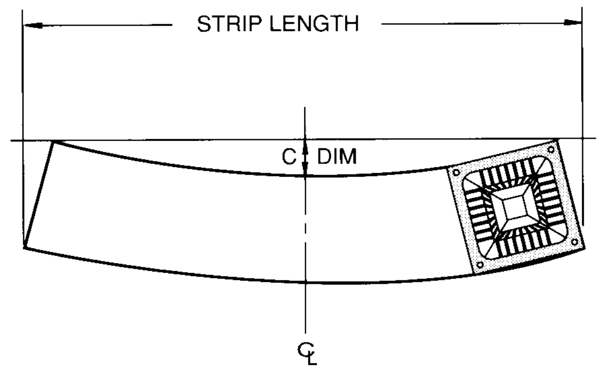

Figure 1
Camber

coined area — that area at the tip end of the bond fingers coined to produce a flattened area for functional use (see Figure 3).

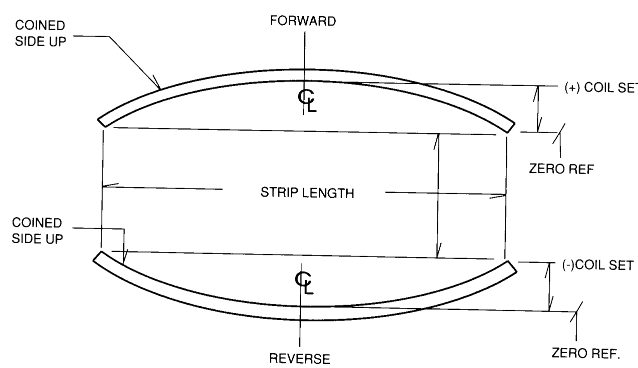

Figure 2
Coil Set

crossbow — transverse bowing of the leadframe (see Figure 4).

lead twist — angular rotation of bonding fingers (see Figure 5).

pits — shallow surface depressions or craters in the leadframe material.

true position circle — that circle with its center positioned at the center of the coined lead defines the design position of the lead tip.

4 Ordering Information

Purchasing orders for leadframes for plastic molded quad flat pack packages furnished to this specification shall include the following items:

4.1 Drawing no. and revision level.

4.2 Material, alloy specification.

4.3 Lead count, and confirming no. of units per strip.

4.4 Requirement for material certification.

4.5 Leadframe plating specifications.

5 Dimensions

5.1 Tables 1, 2, 3, and 4.

5.2 Reference Figures 6 and 7 and Details A and B.

6 Defect Limits and Parameters (to measure, see SEMI G10, Standard Method for Mechanical Measurement for Plastic Package Leadframes)

6.1 *Lead Tip Width*

6.1.1 *Minimum Lead Tip Width* — Shall be as agreed to between supplier and purchaser.

6.1.2 *Minimum Flat Wire Bonding Area* — 80% of nominal lead width and 0.025" (0.635 mm) in length.

6.2 *Coining and Metal Clearance*

6.2.1 *Coined Depth* — 0.0005" (0.013 mm) minimum to 30% material thickness maximum (stamped frames only).

6.2.2 Dimensions shown on drawings are before coining.

6.2.3 *Maximum Coining Bulge* — (Stamped frame only) shall not exceed 0.002" (0.051 mm) per edge and shall be governed by metal to metal clearance requirements (lead to lead and lead to pad).

6.2.4 *Metal-to-Metal Clearance* — Shall be as agreed to between supplier and purchaser.

6.3 *Lead Twist* — Shall not exceed 3.5 or 0.0006" (0.015 mm) per 0.001" (0.254 mm) of lead width.

6.4 *Burrs* — Shall be firmly attached and able to withstand a probe force of 10 grams. All burrs vertical and horizontal in any location shall not exceed 0.001" (0.0254 mm).

6.5 *Die Pad Tilt and Flatness* — (See SEMI G10 for measurement method.)

6.5.1 *Tilt* — 0.001" (0.025 mm) maximum per 0.100" (2.54 mm) of length or width in the undepressed state, and 0.002" (0.051 mm) maximum per 0.160" (4.06 mm) of length or width in the depressed state, when measuring corner to corner: overall maximum not to exceed a total of 0.006" (0.152 mm).

6.5.2 *Flatness* — 0.0002" (0.005 mm) per 0.100" (2.54 mm) pad length when measuring from the center to the average of four corners. The corners are defined at 0.005" (0.127 mm) from each edge.

6.6 *Pits and Slug Marks*

6.6.1 Within the functional area and on external leads, no slug marks and pits shall exceed 0.0003" (0.008

mm) in depth and 0.0005" (0.0013 mm) in length (see SEMI G4).

6.6.2 They shall not affect lead strength and shall not exceed 0.001" (0.0254 mm) in depth and 0.002" (0.051 mm) in length in non-functional areas.

6.7 Material thickness for both alloy 42 and copper alloys is 0.006" (0.152 mm), ± 0.00015" (0.0038 mm) for all lead counts.

NOTE — The material thickness tolerance dimension listed in Section 6.7 is currently under committee review and is expected to be revised to ± 0.0002".

6.8 *Internal Position Tolerance* — The centerline of all leadframe features must be within T.P.T. 0.002" (0.051 mm) relative to center line of pilot holes on rail.

6.9 *Progression*

6.9.1 Single progression of one frame is T.P.T. 0.002" (0.051 mm).

6.9.2 Accumulated progression tolerance over the strip length (measured from pitch line tooling hole to pitch line tooling hole, across the strip length minus two units) is within T.P.T. of 0.004" (0.102 mm).

6.10 *Strip Cut Off Location* — Shall be within T.P.T. 0.006" (0.154 mm) of nominal strip length.

6.11 *Strip Width Tolerance* — T.P.T. 0.004" (0.102 mm) for copper and alloy 42 materials.

6.12 *Camber* — Shall not exceed 0.002" (0.051 mm) over nominal strip length.

6.13 *Coil Set* — Maximum of 0.020" (0.508 mm) over the nominal strip length. This does not include material thickness.

6.14 *Cross Bow* — Shall not exceed the following dimensions:

No. of Leads	*Maximum Cross Bow*
52—100	0.006" (1.52 mm)
132—164	0.010" (0.254 mm)
196—244	0.012" (0.305 mm)

7 Sampling

Sampling will be determined between supplier and purchaser.

8 Packaging and Marking

8.1 *Packaging* — Leadframes must be packaged in containers designed and constructed to prevent damage and contamination.

8.2 *Marking* — The outer containers shall be clearly marked identifying the user stock number, user purchase order number, drawing number, and vendor lot numbers within the carton.

Table 4 (see Figure 7) Guidelines for Placement of Taping Dimensions 84 Lead Through 196 Leadframes

1. Nominal tape width maximum — 0.037"
2. Nominal tape width maximum — 0.060"
3. Tape width tolerance — ± 0.003"
4. Tape location tolerance — ± 0.015"
5. Absolute minimum location of outside tape edge from lead tip — 0.050".
6. Minimum location of outside tape edge from package outline nominal dimension — 0.065".
7. When window "W1" dimension cannot be met with minimum tape nominal width and recommended tolerancing which is the case with various given pad sizes of different lead counts, window "W2" dimension, 0.030", from package outline nominal should be used for the outside tape limit. If this window "W2" dimension still cannot be met negotiation of tape width and location tolerances between supplier and purchaser is suggested to maintain tape within the recommended window dimensions.
8. Recommended center line of tape for nominal location is midway between inside and outside tape edge limits for window "W1" & window "W2" dimensions as appropriate and within tolerance limits.
9. Downset angle — 30°
10. Downsetting must begin inside 0.025" minimum flat distance along tie bar from inside edge of applied tape.
11. Recommended downset length is maximum allowable within the above guidelines.

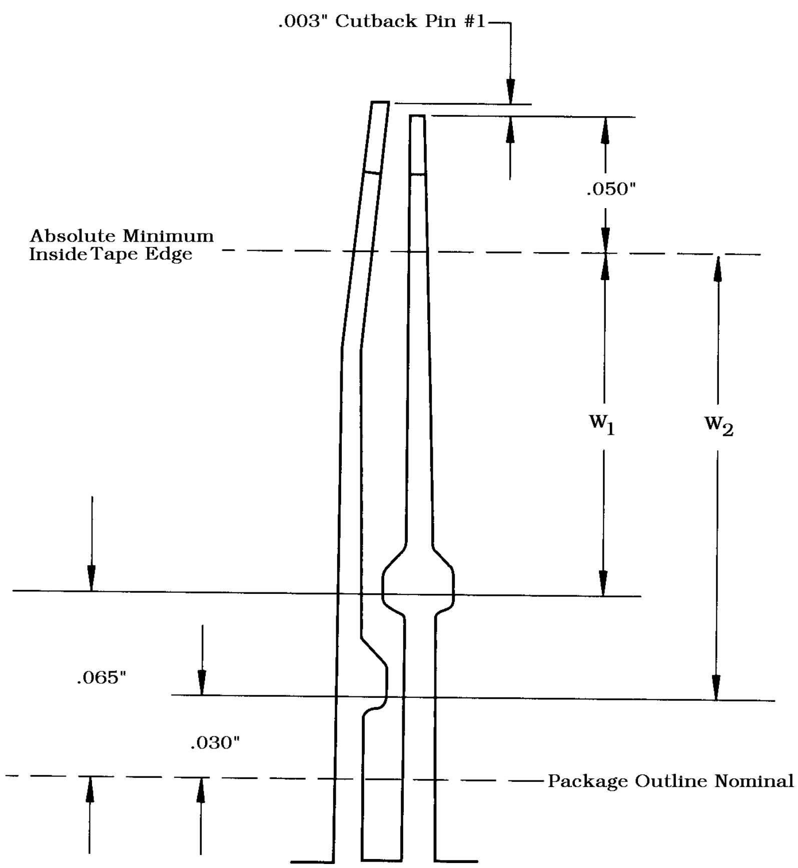

Figure 7

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI G48-89
SPECIFICATION FOR MEASUREMENT METHOD FOR MOLDED PLASTIC PACKAGE TOOLIN

1 Preface

This document is prepared to enable standard measurement techniques to be used. It is intended that the measurement techniques described in the specification will apply to all molded plastic package tooling, i.e. DIPS, SIPS, PCC, SO, Quad, and TAB.

2 Applicable Documents

2.1 *SEMI Specifications*

SEMI G14 — Plastic Molded DIP Tooling

SEMI G16 — Plastic Chip Carrier Tooling

SEMI G36 — Plastic Molded High Density TAB Quad Tooling

SEMI G37 — Plastic Molded SO Package Tooling

3 Basic Equipment

3.1 The following basic equipment is required to perform the specified measurements:

3.1.1 *Toolmaker's Microscope* — 3× objective and 10× eyepiece total 30× with X and Y axes digital readouts reading to 0.0001". Minimum travel of stage must be 2.0" × 2.0". Eyepiece must be ± 0.0002" minimum. The toolmaker's microscope should have a goniometer on the eyepiece as will as on the stage. Accuracy of the goniometer shall be 0.1. The TM microscope should have a Z axis with a digital measurement capability, reading in increments of 0.0001". The objective lens must be 20× minimum which will give 0.0005" accuracy to the Z axis measurements.

3.1.2 *Optical Comparator* — Surface illumination. 10" minimum screen with 3" × 8" minimum travel. Magnification of 10×, 20× minimum required. Accuracy of 10× is 0.001"; accuracy of 20× is 0.0005". Some operators may be able to improve on this accuracy, but this is the best expected from average inspectors.

3.1.2.1 Overlays at 20× may be used for rapid measurement. The user is cautioned that the thickness of the line must be controlled. Line widths must not exceed 0.010" in width, which will give an inaccuracy of 0.0005" in the measurement. Overlays must have the datum marks clearly labeled. Overlays are tools which speed inspection; however, rejects must be verified by toolmaker's microscope measurements, which are more accurate.

3.1.3 *Digital Depth Indicator* — Mounted on a stand. Digital reading with a range of 2" is available. Readout must display increments of 0.0001" with ± 1 digit accuracy.

3.1.4 *Micrometer* — 0 to 1.0". 0.250" diameter for measuring to 0.001" accuracy.

3.1.5 Eight (8) inch dial calipers for measuring to 0.002" accuracy.

3.1.6 *Granite Surface Plate* — Minimum size 18" × 28", with a surface accuracy of 0.0002" or better.

3.1.7 *Surface Finish*

3.1.7.1 *Charmille Visual Surface Finish Standard* — (For comparison of Electric Discharge Machined (EDM) surface only.)

3.1.7.2 *Surface Comparator Standards* — (For other machined surfaces.)

3.1.7.3 *Surface Analyzer*

3.1.8 *Binocular, Zoom Microscope* — 10—15× magnification with vertical or near vertical lighting.

3.1.9 *Dial Indicators* — With accuracy of .0001 and with force not to exceed 5 grams.

3.2 *Alternative Equipment* — Sophisticated, automatic equipment is not excluded from use, but the user must ensure that such equipment meets or exceeds the accuracy of the basic equipment so that correlation problems may be avoided.

3.3 *Calibration* — All equipment to be calibrated on a regular schedule.

4 Measurements

4.1 The following measurements will be made:

4.1.1 Package Thickness (Section 5.1)

4.1.2 Package Length (Section 5.2)

4.1.3 Package Width (Section 5.3)

4.1.4 Leadframe to Cavity Offset (Section 5.4)

4.1.5 Top Cavity Length (Section 5.5)

4.1.6 Top Cavity Width (Section 5.6)

4.1.7 Bottom Cavity Length (Section 5.7)

4.1.8 Bottom Cavity Width (Section 5.8)

4.1.9 Cavity Overlap/Underlap (Section 5.9)

4.1.10 Cavity to Cavity Mismatch (Section 5.10)

4.1.11 Cavity Depth (Section 5.11)

4.1.12 Molding Protrusions (Section 5.12)

4.1.13 Pin Depths (Section 5.13)

4.1.14 Dambar Trimming Defects (Section 5.14)

4.1.15 Package Warpage (Section 5.15)

4.1.16 Lead Coplanarity (Section 5.16)

4.1.17 Shoulder Bend Location (Section 5.17)

4.1.18 Surface Finish (Section 5.18)

4.1.19 Radii (Section 5.19)

4.1.20 Lead Position (Section 5.20)

4.1.21 Draft Angles (Section 5.21)

4.1.22 Lead Spread (Section 5.22)

4.1.23 Foot Angle (Section 5.23)

4.1.24 Foot Length (Section 5.24)

4.1.25 Plastic Stand-off (Section 5.25)

4.2 *Conditions*

4.2.1 All measurements to be made on molded components, which have been processed to agreed conditions including post mold cure.

4.2.2 All measurements to be performed at a temperature between 20° and 26.7°C (68°, 80°F).

4.2.3 *Axis Definition*

4.2.3.1 The X axis lies parallel to the rail of the frame and the Y axis lies perpendicular to the rails of the frame.

4.2.3.2 The package X and Y axes must be positioned parallel to the X and Y axes of the measurement stage travel to avoid measurement errors.

4.2.3.3 The datum of the X and Y axes is the pilot hole of the leadframe, because it is the most accurate feature. An additional pilot hole is required to establish the theta datum.

4.2.3.4 The Z axis is perpendicular to the X and Y axis. The datum is the leadframe or the top mold parting line, unless otherwise specified.

5 Measurement

5.1 *Package Thickness* — (Figure 1)

5.1.1 *Equipment* — Micrometer

5.1.2 Using the micrometer, measure the thickness of the package at three (3) places, diagonally across the package, where the contours allow, at the top edge, middle and bottom edge of the package. (Note: the top is the pin 1 identifier edge.)

5.2 *Package Length* — (Figure 1)

5.2.1 *Equipment* — Optical Comparator at 10×.

5.2.2 Position the package so that the cross-sectional view is presented for measurement. Use care to assure the package is square to the datum plane.

5.2.3 Align the package side draft angle (see Section 5.21) where the draft angle intersects the leadframe. This is the parting line (datum point). Measure the overall width at the parting line, including cavity mismatch.

5.3 *Package Width* — (Figure 1)

5.3.1 *Equipment* — Optical Comparator at 10×.

5.3.2 Position the package so that the cross-sectional view is presented for measurement. Use care to assure the package is square to the datum plane.

5.3.3 Align the package side draft angle (see Section 5.21) where the draft angle intersects the leadframe. This is the parting line (datum point). Measure the overall width at the parting line including cavity mismatch.

5.4 *Leadframe to Cavity Offset* — (Figure 2)

5.4.1 *Equipment* — Toolmaker's Microscope at 30×.

5.4.2 Position the circle (cross hair) of the filar eyepiece of similar diameter to the leadframe pilot hole. Zero the digital readout. Move the stage to the point where the molded package meets the leadframe at the parting line. Record digital readout reading as (T1). Continue to move the stage until the point on the opposite side where mold compound and leadframe meet. Record digital readout reading as T2. Continue to move stage to center of leadframe rail (usually also a hole). Record the digital readout reading as T3.

5.4.3 Turn part over and BE SURE TO USE THE SAME HOLE AND PART; repeat the three (3) readings, B1, B2, and B3.

5.4.4 Derive the data from the readings as follows:

Top Centerline of Frame = (T3)/2

Bottom Centerline of Frame = (B3)/2

Measurement Error = (T3)/2 - (B3)/2

Frame Cavity Offset = (B3)/2 - (B2 + B1)/2

Centerline of Package = (T2 + T1)/2; (B2 + B1)/2. (Relative to datum)

NOTE: Figure 2 calculations assume that the leadframe centerline is equidistant between T3 and the zero datum point.

5.4.5 In lieu of the frame pilot hole, the dambar may be used on the frame when measuring the offset; however, the possibility of tolerance error may become cumulative, particularly with etched rather than stamped frames.

NOTE: By SEMI convention the offsets are defined in relation to the bottom cavity of the mold.

5.5 *Top Cavity Length "Y" Axis* — (Figure 2)

5.5.1 *Equipment* — Toolmaker's Microscope at 30×.

5.5.2 Focus the microscope on the leadframe datum point. Zero the digital readout. Move the stage to the intersection of the mold compound and the leadframe parting line. Read and record. Continue to measure across the package length to the intersection of the mold compound and the leadframe parting line on the opposite edge of the package. Read and record.

5.5.3 The cavity length is defined as (Ty2 – Ty1).

5.6 *Top Cavity Width "X" Axis* — (Figure 2)

5.6.1 *Equipment* — Toolmaker's Microscope at 30×.

5.6.2 Focus the microscope on the leadframe datum point. Zero the digital readout. Move the stage to the intersection of the mold compound and the leadframe parting line. Read and record the reading. Continue on to the intersection of the mold compound and the leadframe parting line on the opposite side. Read and record.

5.6.3 The cavity width is defined as Tx2 – Tx1.

5.7 *Bottom Cavity Length "X" Axis* — (Figure 2)

5.7.1 *Equipment* — Toolmaker's Microscope at 30×.

5.7.2 Focus the microscope on the same datum point used for the top cavity length (remember the package has been turned over). Zero the digital readout. Move to the intersection of the mold compound and the leadframe parting line. Read and record the reading. Continue to the intersection of the mold compound and the leadframe parting line on the opposite side. Read and record. The bottom cavity length is the difference of the two readings. Record the bottom cavity length (By2 – By1).

5.8 *Bottom Cavity Width "X" Axis* — (Figure 2)

5.8.1 *Equipment* — Toolmaker's Microscope at 30×.

5.8.2 Focus the microscope on the leadframe datum point. Zero the digital readout. Move the stage to the intersection of the mold compound and the leadframe parting line. Read and record. The bottom cavity width is the difference of the two readings (Bx2 – Bx1).

5.9 *Cavity Overlap/Underlap* — (Figure 4)

5.9.1 Compare the top cavity length to the bottom cavity length and the top cavity width to the bottom cavity width. The difference in the number is the overlap/underlap for each axis.

5.10 *Cavity to Cavity Mismatch* — (Figure 2)

5.10.1 The comparison of the centerlines of the top cavity length to the bottom cavity length and the top cavity width to the bottom cavity width shall determine the cavity to cavity mismatch.

Formula:

Cavity to Cavity Mismatch =

(B2 + B1)/2 – (T2 + T1)/2

5.11 *Cavity Depth* — (Figure 1)

5.11.1 *Equipment* — Depth Indicator

5.11.2 *Top Cavity Depth* — Measure the distance from the top surface of the leadframe to the top of the unit, place the indicator on the surface of the leadframe, zeroing the readout, moving the part to a point where the top of the unit can be indicated, and read and record the readout.

5.11.3 *Bottom Cavity Depth* — The measurement is performed in the same manner as the measurement in Section 5.11.2 except the part is turned over and the bottom surface of the leadframe to the bottom of the unit is used.

5.11.4 The package depth is the sum of the frame thickness and the top and bottom depth. (This measurement should equal Section 5.1. Any variation may be considered measurement error.)

5.12 *Molding Protrusions Top/Bottom of Part* — (Figure 3)

5.12.1 *Equipment* — Digital depth indicator.

5.12.2 Place unit on the anvil and zero the indicator on the package surface away from area of protrusion. Carefully move the part to where the protrusion is located. Carefully lower the indicator to the top of the mold protrusion. Read and record the mold protrusion.

5.13 *Pin Depths* — (Figure 3)

5.13.1 *Equipment* — Depth indicator with a fine point or "Z" axis reading toolmaker's microscope.

5.13.2 The measurement is made from the nominal plane of the package surface to the bottom of the design mark (either ejector pin or Pin #1 indicator or other feature).

5.13.3 The indicator is set to zero on the package surface and then moved to the bottom of the feature. The readout is read and recorded.

5.14 *Dambar Trimming Defects* — (Figure 4)

5.14.1 *Equipment* — Toolmaker's Microscope

5.14.2 Measure from the edge of the lead to the edge of the protrusion or intrusion; record the reading and the lead number.

NOTE: Dambar trimming defects are those which can be caused by overcutting into the lead shoulder (stand off) i.e. cutting too much or undercutting the dambar, leaving too much dambar or a burr. Overcutting causes shoulder intrusions. Undercutting leaves shoulder protrusions. In some cases, an adjacent protrusion and intrusion is caused by misalignment of the part at the time of dambar removal.

5.15 *Package Warpage* — (Figure 5)

5.15.1 *Equipment* — Microscope "Z" Axis reading 40×.

5.15.2 With the package sitting on the stage, obtain a two point datum by measuring two-points on opposite edges 0.005 from the radius readings; move to the center of the package and obtain the deviation from the datum, and read and record the reading as the warp.

5.15.3 For quad packages, it is equally important that there be minimum warp in each axis (X or Y) so that a three-point Z axis datum must be obtained; the two used in 5.15.2 and an additional one, on one adjacent edge.

5.16 *Lead Coplanarity*

NOTE: Applies to all surface mount devices.

5.16.1 *Contact Method* — (Figure 6)

NOTE: Not recommended for gull-wing leads.

5.16.1.1 *Equipment*

Dial Indicator 0.0001" Accuracy, 5 grams maximum pressure.

Granite Flat.

Transfer Stand.

Package Holding Fixture.

Reference Gauge Blocks, 0.0002" Accuracy.

5.16.1.2 Place the package on holding fixture so that the flat sections of the leads, as they exit from the plastic, are on the ground flats of the fixture. The leads are to be facing "UP" (Dead Bug).

5.16.1.3 On the granite flat, set up the dial indicator on its transfer stand and zero the reading using the reference block. Use a suitable reference block so that all measurements are positive to avoid confusion.

5.16.1.4 Measure the highest point on each lead (e.g., the tangent point of a "J" lead).

5.16.1.5 Determine the range of readings.

NOTE: Special Precautions

1. Be sure that the flat of the leadframe, as it exits from the plastic, rests on the flats of the holding fixture. If the radiused section supports the package, then spurious readings will result.

2. The pressure exerted by the dial indicator must not exceed 5 grams. To check the contact pressure of the dial indicator, use a gram gauge. The gram pressure must be noted at the initial deflection of the gauge and at the maximum deflection of the gauge. If the initial deflection is greater than 5 grams, then the point where 5 grams is obtained must be noted and the measurement must stay within this range to be valid.

5.16.2 *Comparator/Mirror Method*

5.16.2.1 *Equipment* — Optical comparator with at least 20× magnification as per Section 3.1.2. Mirror, flat within 0.0005 inch with a mirror finish having the reflective suface on top. (A polished silver wafer is suggested.)

5.16.2.2 Place the mirror on the measurement stage mirrored side up with the mirror in the plane of the XY axis. Place the package on the mirror with the leads down. Sufficient mirror must extend past the leads toward the lens of the comparator so that an image of the leads with its reflection can be viewed. Focus on the leads nearest the lens. (Care must be taken not to focus on the leads on the opposite side of the package.) (See Figure 8.)

5.16.2.3 Measure the distance between the lead tip and its reflection. Divide that measurement by two to obtain the coplanarity of the lead.

5.16.2.4 Repeat for each lead. Rotate part to measure all sides. Determine co-planarity by identifying maximum measurement.

5.17 *Shoulder Bend Location* — (Figures 1, 7, and 7a)

NOTE: This measurement is not precise, since radius tangent locations allow for considerable inspector interpretation.

5.17.1 *Equipment* — Comparator at 20× magnification. (Surface and shadow illumination).

5.17.2 The measurement is made from the intersection of the straight part of the shoulder with the shoulder bend radius of the lead on one side of the package to the same point on the lead on the opposite side of the package. Locate this point on the first lead by lining up the vertical comparator cross hair with the straight of the lead. Bring the center point of the cross hair to this intersection. Zero the readout, move to the opposite lead, and repeat the location of the intersection. Record the measurement.

NOTE: Due to shadowing of leads, only the end leads on the package can be measured. A visual check with a 10 to 20× microscope should be made to check for gross difference of other leads.

5.18 *Surface Finish*

5.18.1 *Comparative Method* — (EDM Finishes only)

5.18.1.1 *Equipment* — Charmille Standard Surface Gauge Binocular Microscope and Light.

5.18.1.2 Insert gauge and molded package to be checked into a holder so that both can be viewed at the same time under the microscope.

5.18.1.3 Estimate the surface finish on the package.

5.18.2 *Absolute Method*

5.18.2.1 *Equipment* — Automatic Surface Analyzer Surface Standards.

5.18.2.2 Calibrate the analyzer using the gauges.

5.18.2.3 Measure the surface finish on the package. The analyzer gives the average roughness (R_a) and the actual surface roughness. Use average roughness for acceptance.

5.18.3 Table of approximate equivalent finishes

	Mirror	*Satin*	*Extra Fine*	*Fine*	*Medium*	*Course*
Micro Inches	4	30 ± 10	50 ± 10	75 ± 10	105 ± 10	145 ± 10
Charmilles	N/A	N/A	18–21	21–24	24–27	27–30
Microns	N/A	1	1.5	2	2.5	3.5

5.19 *Radii*

5.19.1 *Comparative Method*

5.19.1.1 *Equipment* — Optical comparator at 20×.

5.19.1.2 Radii are measured by comparison to known radius overlays marked at the same magnification as the comparator.

5.19.2 *Absolute Method*

5.19.2.1 *Equipment* — Toolmaker's Microscope.

5.19.2.2 Radii are measured using the reticle lines and the X and Y axes to obtain the radius.

5.19.2.3 Care must be taken to assure that each radius is measured separately.

5.20 *Lead Position*

NOTE: Lead position is a combination of pitch variations due to lead movement after forming and lead width. If the lead is to fit a solder pad or hole, the combination must be considered. In some cases, the lead width can be a major contributor to poor lead position, eg. SO packages with gull-wing leads, PCC with J bend.

5.20.1 *Comparative* Method

NOTE: This method will only determine if the part is usable, not the breakdown of width and pitch variations.

5.20.1.1 *Equipment* — Optical Comparator at 20×.

5.20.1.2 Align the package to an overlay displaying limit lines for lead pitch/width.

5.20.2 *Absolute Method*

5.20.2.1 *Equipment* — Toolmaker's Microscope.

5.20.2.2 Move to the edge of the lead number and zero the readout.

NOTE: Where there is a definitive end to the lead as in the case of SO, SIP and DP, the end of the lead at the intersection of the lead in feature, will be the measurement point. Quad PCC packages will be measured at the top of the "J" bend when in the "Dead Bug" position.

5.20.2.3 Move to the opposite edge of that lead and record width.

5.20.2.4 Move to the first edge of the next lead. Record the measurement. Repeat the width measurements.

5.20.2.5 Repeat for all leads to be measured.

5.20.2.6 Pitch can be calculated from the measurements.

5.21 *Draft Angles*

5.21.1 *Package Sides*

5.21.1.1 *Equipment* — Optical comparator at 10x.

5.21.1.2 Lay the top or bottom surface of the package squarely onto the comparator to insure that no protrusions on the surface cause the package to be tilted. Align the horizontal cross-hair to the leadframe. Using the vertical cross hair, compare the draft angles to an overlay.

NOTE: This measurement should be taken before the leads are formed.

5.21.1.3 Repeat the procedure for all sides of the package.

5.21.2 Pin Marks (e.g., Pin 1 indicator at end of package).

5.21.2.1 *Equipment* — Toolmaker's Microscope.

5.21.2.2 Focus the microscope on the surface of the package and measure the diameter of the pin hole. (D1)

5.21.2.3 Focus on the bottom surface of the pin hole and measure the diameter. (D2)

5.21.2.4 Tangent of Draft angle = (D1 – D2)/2H where H is pin depth from Section 5.12 or cavity thickness.

5.21.2.5 In some cases ejector pin holes may require measurement if a deep hole is specified.

5.22 *Lead Spread* — (Figures 1, 7, and 7a)

5.22.1 *MDIP, SO* — (Figure 7, 7a)

5.22.1.1 *Equipment* — Optical Comparator at 10× Magnification.

5.22.1.2 Place the package squarely on the comparator with the leads "UP" and find the mid-point of the bottom cavity width.

5.22.1.3 Measure the distance to the outer edge of each row of leads at the widest point of spread.

5.22.2 PCC (J bend lead dimension) (Foot Print) Measure from perpendicular to the greatest extension of the "J" radius of the leads on one side of the package to the perpendicular tangent to the greatest extension of the "J" radius of the leads on the opposite package side. (See Figure 1.)

5.23 *Foot Angle* — (Figure 7)

NOTE: Applies to gull-wing leads.

5.23.1 *Equipment* — Optical Comparator at 20× Magnification. Device Holding Fixture (see Section 5.16).

5.23.2 Place the device in the fixture, so that the flat section of the leadframe at the junction with the plastic body rests on the fixture's flats. Leads to be facing "UP".

NOTE: Do not rest the radiused sections of the leads on the flats. Be sure that all mold flash is removed from the area of the frame that rests on the flats.

5.23.3 Measure the angle of the foot with respect to the horizontal.

5.24 *Foot Length* — (Figure 7)

NOTE: Applies to gull-wing leads.

5.24.1 *Equipment* — Optical Comparator at 20× Magnification. Device Holding Fixture (see Section 5.23).

5.24.2 While the foot angle is being measured, place a circle template that contains the same radius as the formed part onto the comparator. Align this template to the radius of the outside bend. Where the radius of the template meets the radius of the outside bend, this is the tangent point to measure foot length.

5.25 *Stand-Off*

5.25.1 Measure the plastic stand-off, when applicable, using the procedures of Section 5.12.

5.26 *Lead Sweep*

5.26.1 *Equipment* — Toolmaker's Microscope or Optical Comparator.

5.26.2 *Method*

5.26.2.1 Determine centerline of lead at egress of lead from molded body (CL1) (see Figure 4).

5.26.2.2 Determine centerline at the end of the lead (CL2). The difference between the two centerlines CL2 – CL1, shall be the lead sweep.

NOTE: On "J" lead devices, the end of the lead is defined as the bottom of the "J" lead radius.

5.26.3 *Cautionary Notes*

5.26.3.1 Verify centerlines on leadframe before measuring to ensure lead-frame is correct.

5.26.3.2 Verify lead position in relation to the top cavity centerline.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI G49-93
SPECIFICATION FOR PLASTIC MOLDING PREFORMS

1 Preface

1.1 *Scope* — This specification defines the physical requirements for preforms made with thermosetting molding compounds.

1.2 *Significance* — Consistent preform quality enhances moldability and finished product reliability.

1.3 *Units* — SI or American Customary units may be used at the customers discretion. This specification uses SI units.

2 Applicable Document

2.1 *ASTM Specification*[1]

ASTM D 792 — Specific Gravity and Density of Plastic

3 Terminology

molding preform — Mold compound powder compressed into a cylindrical shape and size with specified diameter, weight, and density.

scoring — Marks, grooves, scratches, or notches with definite length, width, and depth physical characteristics.

side porosity — Voids or holes with visible shape, size, and depth that are detected around a molding preform.

4 Ordering Information

Purchase orders for preforms furnished to this specification shall include the following items:

Molding compound name/type

Preform diameter

Preform weight

5 Preform Specification

5.1 *Appearance* — The preform appearance, considering such items as side porosity, scoring and breakage shall be defined by agreement between supplier and customer.

5.2 *Preform Density as Percentage of Molded Density*

5.2.1 *Specification* — The minimum values for Preform Density as a Percentage of Molded Density for preforms of various diameters are shown in Table 1.

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohoken, PA 19428-2959

Table 1

Nominal Preform Diameter (mm)	*Percentage of Molded Density (% Minimum)*
< 16	87
> 16	85

5.2.2 *Calculation*

5.2.2.1 *Preform Density* — Measure weight, height, and diameter of preform.

Volume of approximately cylindrical preform (cm^3) =

$$\text{Height(cm)} \times \pi \times \frac{(\text{Average Diameter(cm)})^2}{4}$$

$$\text{Preform Density(g/cm}^3\text{)} = \frac{\text{Weight of Preform(g)}}{\text{Volume of Preform(cm}^3\text{)}}$$

5.2.2.2 *Molded Part Density* — Determine Molded Part Density (g/cm^3) per ASTM D 792.

5.2.2.3 *Preform Density as Percentage of Model Density.*

$$\begin{array}{c}\text{Preform Density as Percentage} \\ \text{of Molded Density (\%)}\end{array} = \frac{(\text{Preform Density})}{(\text{Molded Part Density})} \times 100$$

5.3 *Preform Diameter Tolerance* — The tolerances on preform diameters for variously sized preforms are shown in Table 2.

Table 2

Nominal Preform Diameter (mm)	*Tolerance (± mm)*
< 16	0.30
> 16	1.25

5.4 *Preform Weight Tolerance* — The weight tolerances for variously sized preforms are shown in Table 3.

Table 3

Preform Weight Range (g)	*Tolerance (± g)*
1.8—4.0	0.15
> 4.0—8.0	0.20
> 8.0—< 15.0	0.25
15—< 16	0.50
16—40	1.00
> 40—80	2.00
> 80—150	3.00
> 150	4.00

NOTE 1: The handling characteristics of some molding compounds may require tolerances different from those shown above.

6 Sampling Plan

The sampling plan for inspecting preforms and the molding parameters shall be agreed between supplier and customer.

NOTE 2: *Recommendation* — It is suggested that a minimum of three preforms be measured. On each preform, height and diameter measurements, to the nearest 0.0254 mm (0.001 inch). Preform weight measurements should be taken to the nearest 0.1 gram.

SEMI G50-89
SPECIFICATION FOR CO-FIRED CERAMIC FINE PITCH LEADED AND LEADLESS CHIP CARRIER PACKAGE CONSTRUCTIONS

1 Preface

This specification defines the standard requirements for co-fired ceramic fine pitch chip carrier constructions, including both top brazed leaded and top metallized leadless configurations. These constructions are for hermetic packaging of various devices, (e.g., high speed, digital VLSI silicon devices), and next-level interconnection to printed wiring assemblies and modules by either lead solder attachment or by “leads last” techniques.

2 Applicable Documents

2.1 *ANSI Specification*[1]

ANSI Y14.5 — Dimensioning and Tolerancing

2.2 *Federal Specification*[2]

QQ-N-290 — Nickel Plating

2.3 *JEDEC Specification*[3]

JEDEC Publication 95 — Registered and Standard Outlines for Solid State Products

2.4 *Military Specifications*

MIL-STD-105 — Sampling Procedures and Tables for Inspection by Attributes

MIL-STD-883 — Test Methods and Procedures for Microelectronics

MIL-STD-7883 — Brazing

MIL-I-23011 — Iron Nickel Alloys for Sealing to Glass and Ceramics

MIL-M-38510 — General Specification for Microcircuits

MIL-G-45204 — Gold Plating, Electrodeposited

3 Selected Definitions

blister (bubble) — ceramics — Any separation within the ceramic which does not expose underlying ceramic material.

blister (bubble) — metal — Any localized separation within the metallization or between the metallization and ceramic which does not expose underlying metal or ceramic material.

bond finger — A region of refractory metallization within the package cavity intended for wirebonding to a microcircuit die pad.

braze — An alloy with a melting point equal to or greater than 600°C.

burr — An adherent fragment of excess parent material at the component edge.

chip-out — A region of ceramic missing from the surface or edge of a package which does not go completely through the package. Chip-out size is given by its length, width, and depth from a projection of the design planform (see Figure 1).

co-fired — A process or technology for manufacturing products in which the ceramic and refractory metallization are fired simultaneously.

contact pad — That metallized pattern to which the leadframe is brazed.

crack — A cleavage or fracture, internal or external.

die-attach surface — A designated dimensional outline area intended for die attach (see Figure 1).

foreign material — An adherent particle other than parent material of that component.

laver — A dielectric sheet with or without metallization that performs a discrete function as part of the package construction.

lead offset — Lead centerlines must be aligned to within 0.254 mm (0.010") of the centerline of corresponding braze pad metallizations.

peeling (flaking) — Any separation from the basis material that exposes the basis material.

projection — An adherent fragment of excess material on the component surface.

pullback — The linear distance between the edge of the ceramic and the first measurable metallization surface (see Figure 3).

rundown — The linear distance down a vertical surface from the top to the point of maximum metallization over-hand (see Figure 3).

1 ANSI, 1430 Broadway, New York, NY 10018

2 Military Standards, Naval Publications and Form Center, 5801 Tabor Ave., Philadelphia, PA 19120

3 JEDEC, 2001 Eye Street, N.W., Washington, D.C. 20006

seal area — A dimensional outline area designated for either metallization or base ceramic to provide a surface area for lid sealing (see Figure 2).

terminal — Metallization at the point of electrical contact to package interior circuitry; also the brazing surface for a lead.

TIR — Total indicator reading; the span of readings, from minimum to maximum, of a given dimension over the total surface it applied to.

voids (ceramics) — An absence of screen printed ceramic from a designated area greater than 0.75 mm (0.003") in diameter.

metal — An absence of refractory metallization, braze, or plating material from a designated area greater than 0.075 mm (0.003") in diameter.

4 Ordering Information

4.1 Purchase orders for co-fired ceramic packaged devices shall specify the following information:

1. Quantity
2. Drawing number and revision level or date
3. Reference to this specification
4. Any exception to drawing or specification

4.2 Drawings for co-fired ceramic packaged devices shall specify the following information:

1. Drawing number and revision level
2. Number of terminals and terminal centerline spacing
3. Lead material, finish, and dimensions, if applicable
4. Ceramic material color and composition; and refractory metal type
5. Type and thickness of plating on both device body and leads, if applicable
6. Dimensioning and tolerancing per ANSI Y14.5
7. Internal bonding pattern
8. Lead number 1 position
9. Method of test and measurements
10. Electrical, mechanical, and environmental requirements

5 Dimensions and Permissible Variations

Packaged device dimensions shall conform to JEDEC JC-11 registered outline dimension drawings for co-fired ceramic fine pitch leaded and leadless chip carriers, unless otherwise specified.

6 Materials

6.1 *Ceramic*

6.1.1 Alumina content to be 90% minimum. Beryllia content to be 99% minimum.

6.1.2 Color to be black, dark brown, or dark violet unless otherwise specified.

6.2 *Metals* — External metal surfaces shall be in accordance with MIL-M-38510.

6.3 *Braze* — Copper/silver per MIL-STD-7883.

6.4 *Refractory Metallization* — To be per MIL-M-38510, Type C.

6.5 *Leadframe* — Fully annealed iron nickel cobalt alloy (per MIL-M-38410, Type A) or iron nickel alloy (per MIL-M-38510, Type B).

6.6 *Microcircuit Finishes* — Shall be per MlL-M-38510 unless otherwise specified.

7 Incoming Test Sequence

1. Visual inspection
2. Dimensional check
3. Electrical parameter testing
4. Sampling testing of plating quality, die attach, die shear, wire bond, pull, seal, hermeticity, lead integrity, and solderability

8 Visual Criteria (10× Magnification)

8.1 *Cracks* — None allowed per MIL-STD-883, Method 2009.

8.2 *Chips*

8.2.1 *Corner* — 0.762 mm (0.030") × 0.762 mm (0.030") × one tape layer thickness, maximum.

8.2.2 *Edge* — 0.54 mm (0.100") × 0.762 mm (0.030") × one tape layer thickness, maximum.

8.3 *Burrs, Projections, and Blisters* — Must fit within outline limit.

Top plane excluding seal area — 0.102 mm (0.004"), maximum

Unmetallized seal area — 0.0762 mm (0.003"), maximum

Metallized seal area — 0.025 mm (0.001"), maximum

Bottom surface — 0.051 mm (0.002"), maximum

Edges — 0.152 mm (0.006"), maximum

Terminal pads — 0.051 mm (0.002"), maximum

Wire bond fingers — 0.025 mm (0.001"), maximum

Die attach surface — 0.025 mm (0.001"), maximum

8.4 *Camber* — 0.004" inch/inch (mm/mm), maximum. For dimensions less than 10.05 mm (0.750"), 0.127 mm (0.003") camber is permitted along any planar dimension of the device package.

8.5 *Seal Area Flatness* — The seal area shall be flat within the limits listed in Table l.

8.6 *Die Attach Surface Flatness* — The die attach surface shall be flat within the limits listed in Table 2.

Table 1 Seal Ring Flatness Limits

Seal Ring OD		*Ring Flatness*
0–0.250"	(0–6.35 mm)	0.002" max. (0.051 mm)
0.251"–0.550"	(6.37–13.97 mm)	0.003" max. (0.076 mm)
0.501"–1.000"	(12.7–25.40 mm)	0.004" max. (0.101 mm)
> 1.000"	(> 25.40 mm)	0.004"/inch (0.101 mm/mm)

Table 2 Die Attach Area Flatness Limits

Die Attach Pad Dimension		*TIR Flatness*
0–0.500"	(0–12.7 mm)	0.002" max. (0.051 mm)
0.501"–0.750"	(12.7–19.5 mm)	0.003" max. (0.076 mm)

8.7 *Voids*

8.7.1 *Seal Area Void* — A maximum of three voids permitted. Not more than two voids per side of 0.010" diameter. Any two voids must be separated by 0.762 mm (0.010") minimum, not to degrade the seal width by more than 25%.

8.7.2 *Terminal Void* — A maximum of two voids per terminal pad permissible. Maximum void diameter acceptable is 0.127 mm (0.005"). Voids may never reduce the minimum terminal width to less than two-thirds of the nominal design dimension.

8.7.3 *Wire Bond Finger Void* — Void free 0.015" back from the bond finger tip.

8.7.4 *Die Attach Surface Voids* — Three voids of 0.010" diameter are the maximum allowed separated by 0.030" minimum.

NOTE: Voids within 0.015" of the cavity wall not included.

8.7.5 *Internal Metallization Voids* — Voids in internal metallization planes or traces shall not break continuity. Specific requirements for resistance and capacitance parameters shall be specified in the purchase order, if applicable.

8.8 *Pattern Metallizations*

8.8.1 *Seal Plane Rundown (internal cavity)* — Not to exceed 25% of the cavity layer thickness.

8.8.2 *Seal Plane Rundown (external to cavity)* — Not to exceed half the nominal design distance to adjacent edge metallization. In no event shall the rundown be closer than 0.254 mm (0.010") to any edge metalization.

8.8.3 *Wire Bond Rundown* — Wire bond finger rundown shall not exceed 25% of the cavity depth or 0.127 mm (0.005"), whichever is smaller.

8.8.4 *Wire Bond Finger Pullback* — Wire bond finger pullback shall not exceed 0.127 mm (0.005") from the nominal design dimension for finger end to cavity edge.

8.8.5 *Seal Plane Pullback* — Seal plane pullback shall not exceed 0.127 mm (0.005") from the nominal design dimension for seal plane metallization to edge.

8.9 *Lead Attachment (when applicable)*

8.9.1 *Voids in Braze* — Braze fillets must be 95% free of voids.

8.9.2 *Lead Alignment* — Brazed leads shall not overhang braze pads.

8.9.3 *Lead Offset* — Lead centerlines must be aligned to within 0.0762 mm (0.003") of the centerlines of corresponding braze pad metallizations.

8.9.4 *Lead-to-Lead Misalignment* — Not to exceed 10% of nominal spacing.

8.9.5 *Dimensional Criteria* — Per JEDEC JC-11 registered outline drawings in JEDEC Publication 95, or as specified on the user drawings.

9 Sampling

Sample sizes must meet requirements of MIL-STD-105 or MIL-M-38510 as agreed to between vendor and customer.

10 Test Methods (Mechanical, Electrical, and Thermal)

10.1 *Gold Plating Thickness* — Shall conform to MIL-G-45204. Gold thickness may be determined using the Beta Backscatter Radiation Method or x-ray fluorescence.

10.2 *Nickel Plating* — Shall conform to QQ-N-290. Nickel thickness may be determined using the Beta Backscatter Radiation Method or x-ray fluorescence.

10.3 *Destructive Die Shear Testing* — Shall be performed per Method 2019 of MIL-STD-883.

10.4 *Wire Bond Pill Testing* — Shall be performed per Method 2011, Condition D of MIL-STD-883.

10.5 *Temperature Cycling Testing* — Shall be performed per Method 1010, Condition C of MIL-STD-883.

10.6 *Thermal Shock Testing* — Shall be performed per Method 1011, Condition C of MIL-STD-883.

10.7 *Constant Acceleration Testing* — Shall be performed per Method 2001, Condition E, Y axis only, of MIL-STD-883.

10.8 *Mechanical Shock Testing* — Shall be performed per Method 2002 of MIL-STD-883.

10.9 *Insulation Resistance Testing* — Shall be performed per Method 2002 of MIL-STD-883.

10.10 *Internal Water Vapor Content Testing* — Shall be performed per Method 1018 of MIL-STD-883.

10.11 *Hermeticity Testing* — Shall be performed per Method 1014, Condition A of MIL-STD-883. The hermetic integrity of the packaged device must be maintained after all testing.

10.12 *Lead Integrity Testing* — Shall be performed per Method 2004, Condition A, B1, and B2 of MIL-STD-883.

10.13 *Solderability Testing* — Shall be performed per Method 2003 of MIL-STD-883.

10.14 *Moisture Resistance* — Shall be performed per Method 2003 of MIL-STD-883.

11 Packaging and Marking

11.1 *Packing* — Containers selected shall be strong enough and suitably designed to provide maximum protection against crushing, spillage, and other forms of damage to the container or its contents. Containers shall afford protection of the contents to contamination from exposure to excessive moisture or oxidation by gases. Packaging materials shall be so selected to prevent any contamination of the ceramic component part with paper fibers or organic particles.

11.2 *Marking* — The outer containers shall be clearly marked identifying:

1. Vendor part number
2. Customer part number
3. Quantity
4. Date of manufacture
5. Vendor lot number

12 Applicability

This specification is intended to apply to packages fabricated to the outline requirements for the fine pitch leaded and leadless chip carriers included in JEDEC Publication 95.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI G51-90
SPECIFICATION FOR PLASTIC MOLDED (METRIC) QUAD FLAT PACK LEADFRAMES

1 Preface

This specification defines the acceptance criteria for leadframes designed for assembly of JEDEC proposed registered Publication 95 Standard Outlines for the Metric Quad Flat Pack Family Packages. It is a design guideline for packaging engineers, leadframe stampers and etchers, and mold and trim/form tooling manufacturers. It has been developed to meet the requirements of assemblers using automatic and manual equipment.

2 Applicable Documents

2.1 *Order of Precedence* — To avoid conflicts, the order of precedence when ordering tooling shall be as follows:

Purchase Order

This Specification

Referenced Documents

2.2 *Reference Documents*

2.2.1 *SEMI Specifications*

SEMI G4 — Specification for Integrated Circuit Leadframe Materials Used in the Production of Stamped Frames

SEMI G10 — Standard Method Mechanical Measurement for Plastic Package Leadframes

SEMI G18 — Specification for Integrated Circuit Leadframe Material Used in the Production of Etched Frames

SEMI G21 — Specification, Plating Integrated Circuit Leadframes

2.2.2 *ANSI Specification*[1]

S Y 14.5 M-1982 — Dimensioning and Tolerancing

2.2.3 *JEDEC Specification*[2]

Reg.Prop. 11-286 — Metric Quad Flat Pack Family (Gullwing)

2.2.4 *Military Specification*[3]

MIL-STD-105 — Sampling Procedures and Tables for Inspection by Attributes

3 Selected Definitions

burr — a fragment of excess material either horizontal or vertical attached to the leadframe.

camber — curvature of the leadframe strip edge (see Figure 1).

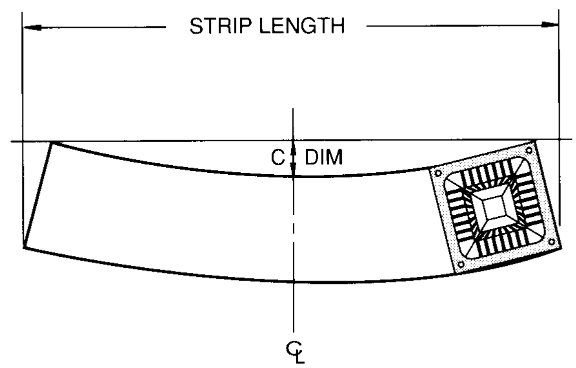

Figure 1
Camber

coil set — longitudinal bowing of the leadframe (see Figure 2).

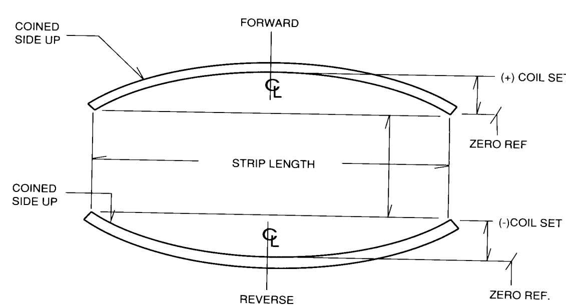

Figure 2
Coil Set

coined area — that area at the tip end of the bond fingers coined to produce a flattened area for functional use (see Figure 3).

2 JEDEC, 2001 Eye Street N.W., Washington, D.C. 20006

3 Military Standards, Naval Publications and Form Center, 5801 Tabor Avenue, Philadelphia, PA 19120

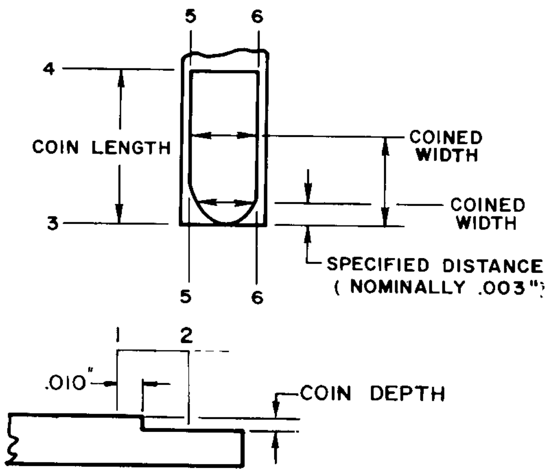

Figure 3
Coined Area

crossbow — Transverse bowing of the leadframe (see Figure 4).

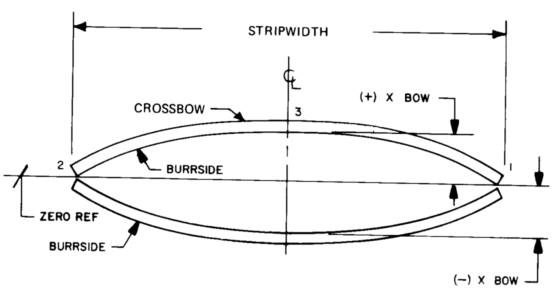

Figure 4
Crossbow

lead twist — Angular rotation of bonding fingers (see Figure 5).

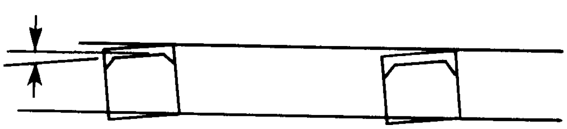

Figure 5
Lead Twist

pits — Shallow surface depressions or craters in the leadframe material.

true position circle — That circle with its center positioned at the center of the coined lead defines the design position of the lead tip.

4 Ordering Information

Purchasing orders for leadframes for plastic Molded Quad Flat Pack packages furnished to this specification shall include the following items:

4.1 Drawing number and revision level.

4.2 Material alloy specification.

4.3 Lead count, and confirming number of units per strip.

4.4 Requirement for material certification.

4.5 Leadframe plating specifications.

5 Dimensions

5.1 Tables I, II.

5.2 See Figure 6 and Detail A.

6 Defect Limits and Parameters

(To measure, see SEMI G10).

6.1 *Lead Tip Width*

6.1.1 *Minimum Lead Tip Width* — Shall be as agreed to between supplier and purchaser.

6.1.2 *Minimum Flat Wire Bonding Area* — 80% of nominal lead width and 0.635 mm (0.025") in length.

NOTE: This applies to stamped frames; percent of nominal lead width for etched frames must be determined between purchaser and supplier and is dependent on etch tolerances.

6.2 *Coining and Metal Clearance*

6.2.1 If coined, maximum depth = 30% material thickness. Minimum depth as agreed to between supplier and purchaser.

6.2.2 On stamped frames, dimensions shown on drawings are before coining.

6.2.3 *Metal-to-Metal Clearance* — Shall be as agreed to between supplier and purchaser.

6.3 *Lead Twist* — Shall not exceed 3.5 or 0.015 mm (0.0006") per 0.254 mm (0.010") of lead width.

6.4 *Burrs* — Shall be firmly attached and able to withstand a probe force of 10 grams. All burrs vertical and horizontal in any location shall not exceed 0.0254 mm (0.001").

6.5 *Die Pad Tilt and Flatness* — (See specification SEMI G10 for measurement method).

6.5.1 *Tilt* — 0.025 mm (0.001") maximum per 2.54 mm (0.100") of length or width in the undepressed state, and 0.051 mm (0.002") maximum per 4.06 mm (0.160") of length or width in the depressed state, when measuring corner to corner: Overall maximum not to exceed a total of 0.102 mm (0.004").

6.6 *Pits and Slug Marks*

6.6.1 Within the functional area and on external leads, no slug marks and pits shall exceed 0.008 mm (0.0003") in depth and 0.0127 mm (0.0005") in length.

NOTE: There is a question regarding the ability of material suppliers to meet this specification. Revision of this specification is under review.

6.6.2 They shall not exceed 0.0254 mm (0.001") in depth and 0.051 mm (0.002") in length in nonfunctional areas.

6.7 *Material Thickness* — 0.150 mm (0.0059") ± 0.005 mm (0.0002") for all lead counts.

6.8 *Internal Position Tolerance* — The centerline of all leadframe features must be within T.P.T. 0.051 mm (0.002") relative to centerline of pilot holes on rail.

6.9 *Lead Tip Coplanarity* — Shall be within the following tolerances as measured relative to the Z datum plane located at the center of the die attach pad or per SEMI G10 measurement method:

44–52 lead counts: ± 0.10 mm (0.004")

64–100 lead counts: ± 0.15 mm (0.006")

120–232 lead counts: ± 0.20 mm (0.008")

6.10 *Progression*

6.10.1 Single progression of one frame is T.P.T. 0.051 mm (0.002").

6.10.2 Accumulated progression tolerance over the strip length (measured from pitch line tooling hole to pitch line tooling hole, across the strip length minus the two end units) is within T.P.T. of 0.102 mm (0.004").

6.11 *Strip Cut Off Location* — Shall be within T.P.T. 0.154 mm (0.006") of nominal strip length.

6.12 *Strip Width Tolerance* — T.P.T. 0.102 mm (0.004").

6.13 *Camber* — Shall not exceed 0.051 mm (0.002") over the nominal strip length.

6.14 *Coil Set* — Maximum of 0.508 mm (0.020") over the nominal strip length. This does not include material thickness.

6.15 *Cross Bow* — Shall not exceed 0.7% of the nominal strip width.

6.16 External nominal lead width dimension will be as follows for each respective lead pitch requirement:

1.0 mm lead pitch: 0.4 mm (stamped or etched)
8 mm lead pitch: 35 mm (stamped or etched)
65 mm lead pitch: 0.27 mm (etched)
3 mm (stamped)

Please note that specific etching and stamping tolerances associated with lead widths are to be negotiated and specified between purchaser and supplier.

PLEASE NOTE: THESE SPECIFICATION DIMENSIONS AND CRITICAL TOLERANCES, UNLESS OTHERWISE NOTED, APPLY TO ALL ALLOY 42, COPPER ALLOY, ETCHED AND STAMPED LEADFRAME MATERIALS.

7 Sampling

A sampling plan and buy-off procedure to determine compliance to the requirements of Sections 5 and 6 and other relevant specifications shall be determined between vendor and customer.

8 Packaging and Marking

8.1 *Packaging* — Tooling must be packed in containers designed and constructed to provide protection against normal transportation damage risks and spillage. The container will offer protection from contamination and exposure to moisture.

8.2 *Marking* — The following details shall be noted on the packing slip:

Quantity and Description

Vendor Lot Numbers

Vendor Part Number

Customer Drawing Numbers

Customer Part Number

Shipping Date

Customer P.O. Number

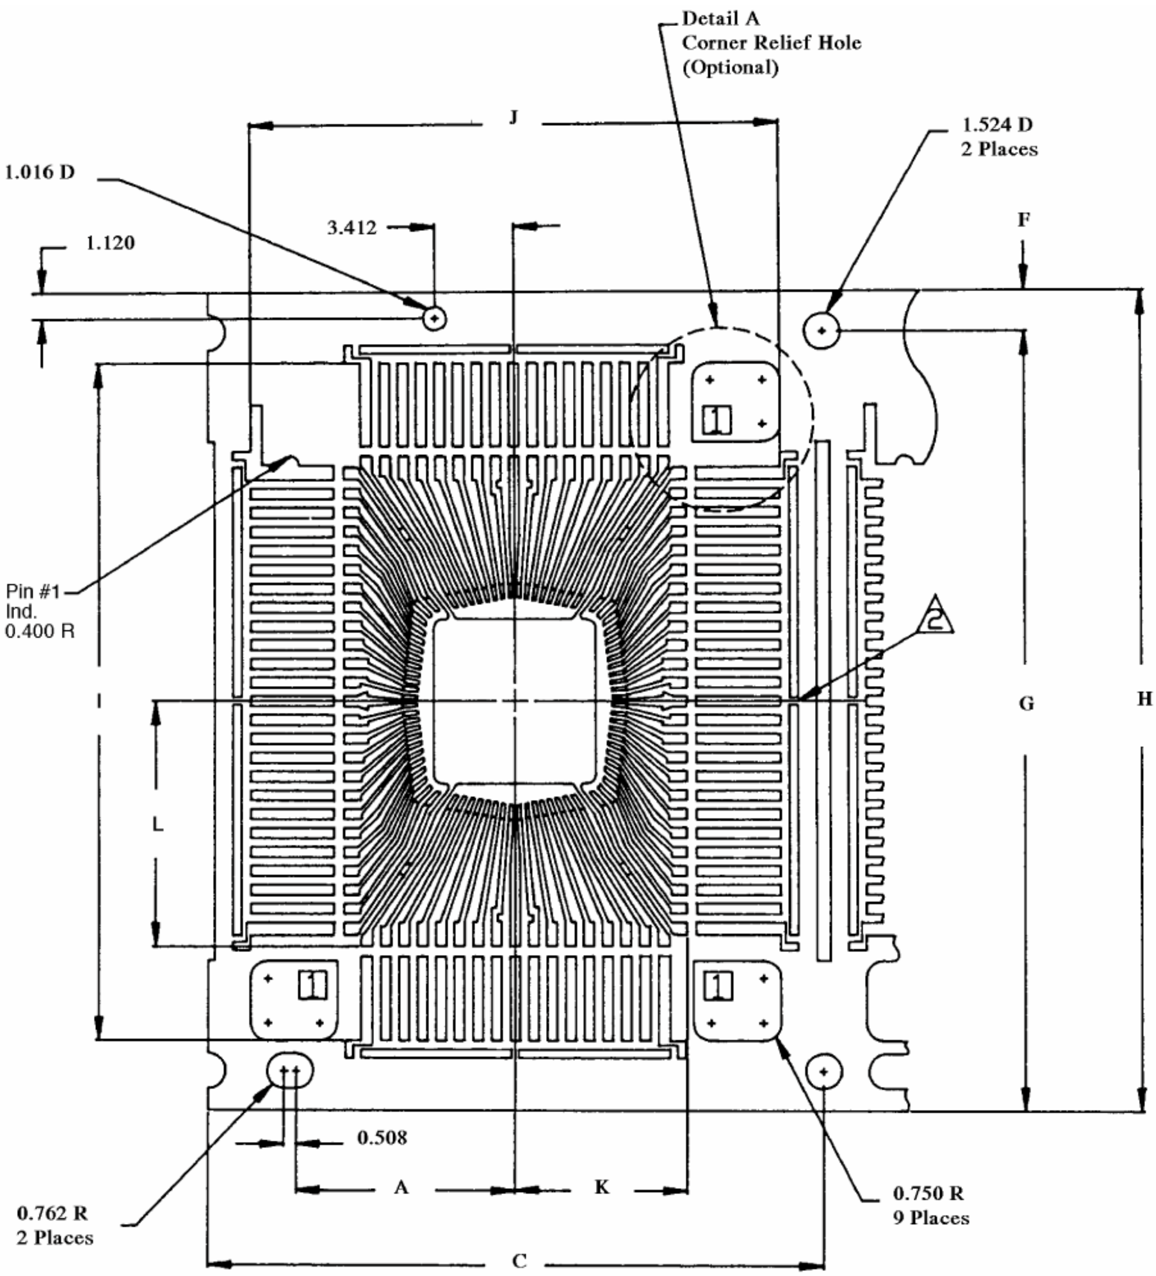

Figure 6
Frame Unit

1. Corner relief holes are optional features only. Gating may require their exclusion.

2. Lead counts 100 and below have only 1 support tab per each frame expansion slot. Lead counts 120 and above have 3 support tabs evenly spaced for each frame expansion slot. Tabs are to be placed opposite the space.

SEMI G52-90
STANDARD TEST METHOD FOR MEASUREMENT OF IONIC CONTAMINATION ON SEMICONDUCTOR LEADFRAMES (PROPOSED)

NOTE: Japan, Europe, and US task forces are planning to develop test methods which will address the different levels of ionic contamination on leadframes.

1 Scope

This standard describes the procedure to determine ionic contamination on leadframes using a water extraction method. The method is sensitive to Na^+, NH_4+, K^+, Cl^-, NO_3-, Br^-, $SO_4$2-, $PO_4$3-.

2 Applicable Documents

2.1 *ASTM Specifications*[1]

D 4327 — Anions in Water by Ion Chromatography

D 1193 — Specification for Reagent Water

3 Summary of Method

Ionic contamination is extracted in water at > 95°C for 30 ± 2 minutes. The contamination is quantitatively analyzed by ion type using Ion Chromatography and the result is presented as nanograms/unit area.

4 Significance

4.1 Contamination on leadframes can contribute to semiconductor device reliability problems. This method may be used by lead frame manufacturers at outgoing inspection and by users at incoming inspection. Correlation of device reliability with contamination levels may lead to improved leadframe cleaning processes.

5 Selected Definitions

5.1 *eluent* — the solvent used to carry the extracted ions through the ion exchange chromatograph.

5.2 *regenerant* — a chemical solution containing the ions originally present in the chromatograph column prior to a test run and used to prepare the column for a new test.

5.3 *standard solution* — a solution containing a known concentration of the ion to be measured and used to calibrate the chromatograph.

5.4 *retention time* — the time required for a particular ion type to pass from the injection port to the detector. Retention time is characteristically different for each ion type.

6 Equipment

6.1 Ion chromatograph for anion and cation analysis. This equipment is to consist of a concentration pump, guard column, separator column, and a detector module consisting of a suppressor device to reduce the background eluent conductivity to a low level and a conductivity cell. The minimum sensitivity of the chromatograph for each ion type is defined in Table 1.

6.2 *Chart Recorder*

6.3 *Ion Extraction Vessels* — Polypropylene or teflon containers with sealing caps, or polypropylene/ polyethylene double layered bags.

Note: The contamination level of these vessels must be less than one-fifth (1/5) of the expected contamination level on the leadframes when measured in a control test.

6.4 Hot bar bag sealer.

6.5 Water bath, 300 mmL × 300 mmW × 200 mmH, filled with DI water, and capable of holding 95°C.

6.6 *Volumetric Dispenser (e.g., Pipettes)* — 10 ml and 100 ml capacity.

6.7 *Quartz Flasks and Pipettes for Cation Standard Solutions* — 100, 250, 500, and 1000 ml capacity (flasks); 1, 10, and 25 ml capacity (pipettes).

6.8 *Borosilicate Glass flasks and Pipettes for Anion Standard Solutions* — 100, 250, 500, and 100 ml capacity (flasks); 1, 10, and 25 ml capacity (pipettes).

6.9 *Chemical Balance, Weighing Chemicals*

6.10 *Scissors, Tweezers, Spatula*

7 Reagents and Materials

7.1 Deionized water, resistivity ≥ 15 megohm centimeters at 25°C per ASTM D 1193.

7.2 Eluents and regenerants for specific chromatograph columns prepared per chromatograph equipment manufacturer's recommendations so that the water peak can be separated from the ionic peaks.

7.3 *Compounds for Cation Standard Solutions* — NaCl, NH_4Cl, KC1.

7.3.1 *Compounds for Anion Standard Solutions* — NaCl, Na_2HPO_4, $12H_2O$, NaBr, $NaNO_3$, K_2SO_4.

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohoken, PA 19428-2959

NOTE: All compounds are to be reagent grade.

8 Sampling

8.1 The leadframes must not be touched, except with previously cleaned tweezers or double-layered cotton gloves with polyethylene outer gloves in order to avoid additional contamination.

8.2 The sample size (i.e., the number of frames to be tested in this destructive test) may be determined by agreement between the customer and the vendor. The recommended sample sizes are 10–50 cm^2 for testing pads and 200–500 cm for the test of overall leadframes.

NOTE: The surface area of the frame is calculated from the leadframe drawing, and includes the top, bottom and side surfaces. It is important that user and supplier agree on the surface area calculation for any given leadframe configuration.

9 Preparation of Standard — Solutions and Chromatograph Calibration

9.1 *Standard Solutions*

9.1.1 The single-ingredient standard solutions of each ion (Na^+, NH_4+, K^+; C^1, No_3-,Br^-, $SO_4$2-, $PO_4$3-) are made by dissolving 1.000 g of each ion into 1.000 liter of D.I. water, respectively. The stored multi-ingredient standard solutions shown in Table 2 are then made form these single-ingredient standard solutions by the dilution method.

9.1.2 Cation and anion standard solutions for calibration are made by diluting the stored multi-ingredient standard solutions as shown in Table 2.

9.1.3 Store the multi-ingredient standard solution and the calibration solutions in the correct flasks and label with the ion type and concentration.

NOTE: New standard solutions for calibration are required every 24 hours. Ensure that the flasks are cleaned with water before refilling with a new solution.

9.2 *Calibration*

9.2.1 Set up the chromatograph and regenerate the columns according to the manufacturer's instructions (ASTM D 4327 provides further details).

9.2.2 Run the eluent through the chromatograph until a stable baseline chromatograph is obtained.

9.2.3 Select the infection volume recommended by the manufacturer for each ion type and inject in to the chromatograph. Record the chromatograph for each ion type (see Figure 1), and make the calibration curve for each ion (ion concentration versus peak height or area).

NOTE: Peak height or area under the ion's characteristic curve is proportional to the concentration.

10 Procedure — Bag Extraction Method

10.1 *Preparation of Extraction Bags*

10.1.1 Add 100 ml of DI water to the polypropylene/polyethylene double layered bag and seal them with the hot bar bag sealer. The amount of air in the bags should be reduced as much as possible before sealing.

NOTE: Two bags are required for each test and must come from the same manufacturing lot.

10.1.2 Place the bags in the water bath at T > 95°C for 2 hours ± 5 minutes.

10.1.3 Allow the bags to reach room temperature but leave sealed until ready for use at which time open the bags (use clean scissors for the bags) and rinse out five (5) times with DI water.

10.2 *Extraction Process*

10.2.1 Place the samples in the bags. Cover the frames with a known volume of water (e.g., 100 ml and then seal the bags). Also, place a similar amount of water in an empty bag and seal.

NOTE: The amount of air in the bags should be reduced as much as possible before sealing. The bags that only contain water provide the background contamination of the bag. Do not select the frames or remove them from their shipping container until ready to test the surface contamination. The recommended volume of water is 10–30 ml for the testing die pads only and 100 ml for testing complete leadframes. Lead frames should be bent after sealing so that the water is in contact with all surfaces.

10.2.2 Place the bags in the water bath at T > 95°C for 30 ± 2 minutes.

10.2.3 Remove the bags from the bath and allow to reach room temperature.

10.2.4 The lead frames, which are inside the sealed bags, are moved to one side of the bags without opening the bags. Then the solution is separated from leadframes by sealing the mean portion of the bags without opening.

11 Procedure — Container Extraction Method

NOTE: The size of the containers to be used depends on the expected volume of water and the leadframes. The container must be at least three-quarters filled with the water and leadframes.

11.1 *Preparation of Extraction Vessels*

11.1.1 Fill the containers with DI water and attach the caps. In order to reduce the amount of air in the vessel, fill vessels to the amount of three-quarter.

NOTE: Two containers are required for each test and must come from the same manufacturing batch.

11.1.2 Place the containers in the water bath at T > 95°C for 2 hours ± 5 minutes.

11.1.3 Remove the containers from the bath and rinse out five (5) times with DI water.

11.2 *Process*

11.2.1 Place the samples in one of the containers cleaned per Section 11.1.1.

NOTE: Leadframes may be cut or rolled in order to ease loading to the container. Die pads may be tested separately, if desired, by cutting from the leadframes.

Add the required volume of DI water and cap the container. Place a similar amount of water into the other cleaned container and attach the cap.

NOTE: Do not select the frames or remove them from their shipping container until ready to test for the surface contamination. Recommended volumes of water are 10 – 30 ml for testing die pads only and 100 ml for the entire leadframe — samples must be covered by water.

11.2.2 Place the containers in the water bath at T > 95°C for 30 ± 2 minutes.

11.2.3 Remove the containers from the bath and allow to reach room temperature.

11.2.4 Remove the leadframes from the container and cap it again.

12 Measurements

12.1 Prepare the chromatograph for operation by regenerating the columns according to the manufacturer's recommendations.

12.2 Run the eluent through the chromatograph until a stable baseline calibration is established.

12.3 Inject the recommended sample size of test solution into the chromatograph and record the ion chromatogram.

12.4 Repeat for all the samples and also run the background sample.

Note: The time from extraction to insertion of sample is to be within eight hours.

12.5 Sample concentrations are determined from the calibration curves for each ion type.

12.6 The surface concentration of ionic contaminants for each ion type (SCIC) is given by the following equation:

$$\text{SCIC}\left(\text{ng/cm}^2\right) = \frac{(\text{Sample conc. - Background conc.}) \times \text{Extraction Volume (mL)}}{\text{Leadframe Surface Area}\left(\text{cm}^2\right) \times \text{No. of Leadframes}}$$

NOTE: Allowable concentration levels are to be agreed between the user and supplier.

Table 1 Sensitivity of Ion Chromatograph

	Ion	*Sensitivity (ng/ml)*
Cation	Na^+	0.2
	NH_4+	0.5
	K^+	1.0
Anion	Cl^-	0.3
	PO_4-	2.0
	Br^-	1.0
	NO_3-	1.0
	SO_4-	1.0

SEMI G53-92
SPECIFICATION FOR METAL LID/PREFORM ASSEMBLY

1 Preface

1.1 *Scope* — This specification provides guidelines for the design and acceptance of metal lid/preform assemblies (see Figure 1). This specification may be used by suppliers at outgoing inspection and by the customers at incoming inspection.

The design and acceptance criteria may be used for metal lid/preform assemblies used on all types of semiconductor packages.

1.2 *Significance* — Improper lid/preform design and poorly specified lid/preforms contributes to low sealing yields and unreliable devices.

1.3 *Units* — U.S. Customary (inch-pound) or SI (metric) units may be used at the customer's discretion. This specification uses U.S. Customary units as the prime unit.

2 Applicable Documents

2.1 *Order of Precedence* — To avoid conflicts, the order of precedence when ordering metal lid-preform assemblies shall be as follows:

Purchase Order

Customer's Lid-Preform Drawing

This Specification

Reference Documents

Related Documents

2.2 *Referenced Documents*

2.2.1 *Military and Federal Specifications*[1]

MIL-STD 883 — Test Methods and Procedures for Microelectronics

MIL-M-38510 — General Specification for Microcircuits

2.2.2 *ANSI Specification*[2]

Y14.5M — Dimensioning and Tolerancing

2.2.3 *ASTM Specification*[3]

B 568 — Measurement of Coating Thickness by X-Ray Spectrometry

E 10 — Standard Test Method for Brinell Hardness of Metallic Materials

E 384 — Standard Test Method for Microhardness of Materials

E 29 — Practice for Using Significant Digits in Test Data to Determine Conformance to Specifications

E 1182 — Measurement of Surface Layer Thickness by Radial Sectioning

3 Definitions

blister — any enclosed localized separation of the plating from the base material or from another layer of plating which can be depressed by a sharp instrument.

bow — relative flatness of the preform to the lid after spot welding.

burr — an adherent fragment of parent material, lid or preform, at the edge of the lid or preform.

chipout — a region of material which is missing from the surface or edge of the lid or preform.

contamination — three dimensional alien material adhering to a surface.

corrosion — electrochemical degradation of the material usually exhibited by discoloration such as rust.

crack — a cleavage or fracture which extends to the surface of the lid or through the preform.

discoloration — any change in the color of the plating as detected by the unaided eye which normally occurs after the application of heat.

foreign material — an adherent particle other than parent material of that component.

NOTE: Adherent means inability to be removed with an air or Nitrogen blow-off at 20 psi.

gouges — mechanically formed depressions in the lid surface.

nodules — lumps of plating extending above the surface of the lid.

oil canning — lid concavity after sealing.

peeling — the lifting of plating from a surface.

pit — a hole or depression extending below the surface of the lid or preform.

preform — a solder material of defined volume that is attached to the base material.

1 Military Standards, Naval Publications and Form Center, 5801 Tabor Avenue, Philadelphia, PA 19120

2 ANSI, 1430 Broadway, New York, NY 10018

3 American Society of Testing and Materials, 100 Barr Harbor Drive, West Conshohoken, PA 19428-29597

protrusion — an adherent fragment of excess material on the surface of lid or preform.

scratch — surface mark which exposes underlying metal.

seal ring — area designated for attaching the lid to the package by welding or soldering techniques.

stain — a two-dimensional substance on a surface of the lid or preform.

tack weld — small spot welds, generally located in the corners which are used to attach the preform to the lid.

void — absence of plating from designated area.

weld splatter — melted preform material which extends from the weld.

4 Ordering Information

Purchase orders for metal lid/preform assemblies furnished to this specification shall include the following information.

4.1 Current customer drawing revision detailing:

All dimensions and tolerances per ANSI Y14.5M

Base material and hardness

Type, and thickness of the plating(s)

Preform type and composition

4.2 Reference to this specification.

4.3 Supplier certification requirements

4.4 Any additions to, or variations from, this specification.

5 Materials

The definitions, design guidelines, defect criteria, and functional tests described in this specification relate to lid/preform assemblies made with the following materials.

5.1 *Lid*

5.1.1 Base material to be Iron Nickel Cobalt alloy per MIL-M-38510, Type A; OR Iron Nickel alloy per MIL-M-38510, Type B <u>unless otherwise stated on the purchase order.</u>

5.1.2 Plating shall meet the requirements of MIL-M-38510 unless otherwise stated in the purchasing document.

5.2 *Preform*

5.2.1 Preform to be 80% (+0/-1% tolerance) gold, balance to be tin unless otherwise stated on the purchase order. Gold and tin to be 99.99% pure per ASTM E 29.

	Maximum Trace Elements
Silver (Ag)	100 ppm
Copper (Cu)	50 ppm
Lead (Pb)	50 ppm
Palladium (Pd)	20 ppm
Iron (Fe)	10 ppm

Others 10 ppm each

Total all impurities: 149 ppm

6 Design Guidelines

These guidelines are based on the use of a furnace sealing process, not seam sealing.

6.1 *General Guidelines*

6.1.1 The I.D. of the lid preform should be 0.010 larger than the package seal ring I.D. as long as preform width specifications are not violated.

6.1.2 The O.D. of the lid should be 0.025" to 0.035" smaller than the package seal ring O.D. as long as preform width specifications are not violated.

NOTE: The dimensions listed are based on nominal tolerances only. The worst case package and lid conditions must be considered.

6.1.3 *Recommendations* — The following table is a guideline only. Specific requirements may differ depending on the package type or style.

Lid Size	*Lid Thickness**	*Preform Thickness*	*Preform Width*	*Pkg.S/r Width*	*Corner Radii*
<0.251"	0.010"	0.0015–0.0021"	0.025" min.	0.0425" min.	0.020–min.
0.251–0.500"	0.010"	0.0021"	0.035" min.	0.0525" min.	"
0.501–0.650"	0.010–0.015"	0.0021–0.0024"	0.035" min.	0.0525" min.	"
0.651–1.000"	0.015"	0.0021–0.0030"	0.040–0.060"	0.0625–0.0675"	"
1.001–1.250"	0.015"	0.0021–0.0030"	0.045–0.065"	0.0675–0.0725	"
>1.250"	0.015"	0.0021–0.0030"	0.050" min.	0.0725" min.	"

* Tolerance for Lid Thickness is ± 10 %.

** Tolerance for Preform Thickness is ± 0.0003".

7 Defect Limits

Visual inspection shall be carried out at 3× magnification with verifiaction at 10×.

alpha emission — Alpha Emission Level Max: 0.05 counts/cm^2/hour +30/-0 seconds. **Test method to be agreed upon between user and supplier.**

blisters/peeling — None allowed after 3 minutes **dwell time** at 400 ± 10°C in air.

bow — Preform bow not to exceed:

Lid Size	*Maximum Allowable Bow*
< 0.500"	0.003"
0.501 – 1.500"	0.005"
1.500" and above	To be determined between supplier and user.

burrs (stamping) — None allowed greater than 0.001" in height.

chipouts — Chipouts exceeding 10% of the width of the preform (may be up to 20% in the corner) are not allowed. No chipouts allowed in lid.

cracks — Cracks in the lid not allowed. The preform shall not be broken, except in such cases where both sides of the break are in contact, and the preform is flat and firmly attached to the lid. Maximum of one (allowable) crack per preform allowed.

discoloration/stains — Discoloration of the finish shall not be cause for rejection unless there is evidence of corrosion or other contamination.

flatness — Lid must be flat within 0.001" per 0.500" T.I.R.

foreign material/contamination — Adherent material which cannot be removed by blowing with 20 psi air or nitrogen is not allowed.

pits — Pits larger than 0.005" are not allowed. No more than three acceptable pits are allowed on either surface of the lid and there must be a minimum of 0.030" between sites. Pits must not have exposed base metal.

NOTE: A sample of lids with pits may be subjected to Salt Atmosphere test per MIL-STD 883, Method 1009, Condition A as a condition of lot acceptance.

plating voids — No plating voids greater than .005" in any dimension. Lids with smaller plating voids may be subjected to Salt Atmosphere Test as described above as a condition of lot acceptance.

preform alignment — Misalignment shall not exceed 0.005" from any one edge of the lid.

preform attachment — Preform to be firmly attached to the lid in at least 3 corner locations.

protrusions — Protrusions larger than 0.005" in any horizontal dimension or 0.001" in height are not allowed.

scratches — Scratches which expose base metal not allowed.

tack weld height — Must be firmly adherent and max 0.003".

7.1 All lids must meet the following criteria:

Salt atmosphere per MIL-STD 883, Method 1009, Condition A

Resistance to Solvents per MIL-STD 883, Method 2015

Gold plating per MIL-M-38510

8 Sampling

The sampling plan shall be agreed upon between user and supplier.

9 Incoming Inspection

9.1 Incoming inspection to be performed per user drawing with reference to this specification.

9.1.1 *Plating Thickness* — Plating thickness shall be measured by X-Ray Fluorescence per ASTM B568. The tolerance on the thickness shall be agreed upon between user and supplier. For multilayer plated lids, additional layers should be measured by cross section.

9.1.2 *Material Hardness* — Hardness shall be evaluated per ASTM E 384 or E 10 to limits agreed upon between user and supplier.

9.1.3 *Functional Testing*

9.1.3.1 Functional testing may be performed at the option of the user or supplier. Test to be agreed upon between user and supplier.

9.1.3.2 Hermeticity parts should be evaluated per MIL-STD 883, Method 1014.

9.1.4 *Marking* — Marking permanency shall be evaluated per MIL-STD 883, Method 2015.

9.1.5 *Corrosion Resistance* — Corrosion resistance shall be evaluated per MIL-STD 883, Method 1009 (Salt Atmosphere).

10 Certification

Upon request of the user in the purchase order, a supplier's certification that the product was manufactured and tested in accordance with this specification, together with a report of the test results, shall be furnished at the time of shipment. Certification to user specification may also be required. This certification does not remove the supplier's responsibility for discrepant product subsequently found by the user.

11 Packaging and Package Marking

11.1 *Packaging* — The shipping containers and materials shall be suitably selected to provide the components with protection from normal transportation damage risks which include crushing, abrasion, spillage, and exposure to moisture and other corrosive gasses. The inner packing materials must be clean room compatible as defined by user.

11.2 *Package Marking*

11.2.1 *Internal Packages* — Each internal package shall be marked as follows:

User's Part Number

User's Order Number

Drawing Number (user's and supplier's, if appropriate)

Plating Lot Number

Manufacturing Lot Number

Quantity Date of Manufacture

External Marking — The external packing list shall include the following details:

User's Part Number

User's Order Number

Quantity Shipping Date

Any specific instructions for receiving personnel

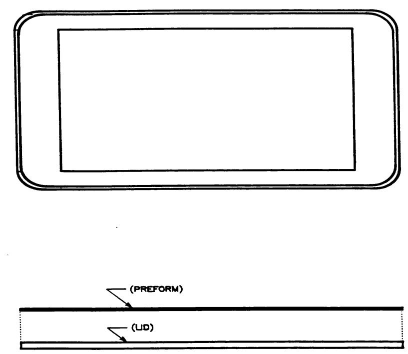

Figure 1

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI G54-93
SPECIFICATION FOR DIMENSIONS AND TOLERANCES USED TO MANUFACTURE MOLDED PLASTIC PACKAGES

1 Preface

This document is a guideline for ordering the tooling required to manufacture plastic semiconductor packages. These packages include the following JEDEC registered outlines:

Plastic Dual-in-Line Packages (PDIP)
Plastic Leaded Chip Carrier (PLCC)
Plastic Quad Flat Packages (PQFP)
Small Outline I.C. Packages (SOIC — Gull Wing and “J” lead)
Plastic TAB Quad Packages (PTAB)

NOTE 1: Package outlines registered with other organizations such as EIAJ and non-registered outlines may use the criteria in this document by choosing the outline which most closely resembles the particular package.

Packaging engineers, mold manufactures, and end-of-line tool makers may use this document to define the limits of tooling tolerances.

2 Applicable Documents

2.1 *Order of Precedence* — To avoid conflicts, the order of precedence when ordering tooling shall be as follows:

Purchase Order
Referenced Documents
This Specification

2.2 *Reference Documents*

2.2.1 *SEMI Specifications*

SEMI G48 — Specification, Measurement Method for Molded Plastic Package Tooling

2.2.2 *JEDEC Specifications*[1]

Pub. No. 95 — Registered and Standards Outline for Semiconductor Devices

2.3 *Related Documents for Information*

2.3.1 *Military Specifications*[2]

MIL-STD-100 — Engineering Drawing Practice

2.3.2 *ANSI Specifications*[3]

Y14.5 — Dimensioning and Tolerancing

3 Selected Definitions

3.1 *Cavity* — the plastic body formed by either the top or bottom mold cavities.

3.2 *Gate Feature* — plastic protrusions or intrusions which result from normal molding and degating operations.

3.3 *Lead Bend Angle* — the angle to which the leads are bent in reference to a plane normal to the X-Y plane of the package. After a suitable radius has been formed at the shoulder, there must be no compound angle formation to achieve the lead spread requirements. Lead Bend Angle may just be a reference if Lead Spread is specified (see Figures 1A, B, C).

3.4 *Lead Coplanarity* — the vertical position of a lead foot with respect to a reference plane created by the three leads with feet most extended from the bottom surface of the package body. The term “foot” applies to both PLCC foot radii and PQFP feet (see Figure 2).

3.5 *Lead Shoulder (Dambar Area) Protrusions or Intrusions* — a protrusion (tab) on the shoulder or lead, or intrusion cut into the shoulder or lead as a result of dambar trimming (see Figures 3 and 4).

3.6 *Lead Sweep* — lead movement measured with respect to a datum, perpendicular to the top or bottom surface of the package and which passes through the midpoint of the lead, when viewed from the sides of the package (see Figure 4).

3.7 *Mismatch* — misalignment between the top and bottom cavities. The measurement of mismatch is stated as the difference between the center lines of the top and bottom cavities (see Figure 5). All statements regarding mismatch of cavities are applicable to both the X and Y axis. All measurements are made prior to lead trim and form.

3.8 *Offset* — the difference in the bottom cavity position from a leadframe datum when compared to design (see Figure 6). This measurement ignores leadframe tolerances. All statements regarding offset are applicable to both the X and Y axis. All measurements are made prior to lead trim and form.

1 JEDEC, 2001 Eye Street N.W., Washington, D.C. 20006

2 Military Standards, Naval Publications and Form Center, 5801 Tabor Avenue, Philadelphia, PA 19120

3 American National Standards Institute, 1430 Broadway, New York, NY 10018

3.9 *Overlap* — the difference in length or width between the top and bottom cavities. Overlap may be a feature designed into the mold to avoid mismatch (see Figure 5). All statements regarding overlap of cavities are applicable to both the X and Y axis. All measurements are made prior to lead trim and form.

3.10 *Package Warpage* — loss of planarity of a molded surface excluding protrusions and intrusions (see Figure 7). Each package type has a maximum allowable warpage and a warp factor is used to determine the maximum warpage for a particular package dimension. The Warp Factor (WF) is defined as follows:

$$\text{WF} = \frac{\text{Total Warp in inches (mm)} \times 1000}{\text{Package dimension in inches (mm)}}$$

Package warpage is usually caused by incorrect package design and/or poor molding conditions.

3.11 *Parting Line Protrusions, or Intrusions* — plastic excesses (flash) or losses (chips or voids) at the parting line after normal processing to mold, deflash, trim, and singulate the packages.

3.12 *Surface Protrusions or Intrusions* — plastic excesses (bumps or blisters) or recesses (pits or voids) on any surface of the package.

4 Ordering Information

Purchase orders for molded plastic tooling furnished to this document, shall include the following items:

4.1 A package tooling outline drawing showing all the required dimensions listed in Section 5. The molded surface finish(es) and the lead finish shall be specified.

4.2 The plastic compound to be used shall be specified. If the compound is proprietary, then the molding and molded characteristics shall be supplied.

4.3 The leadframe drawing detailing the material, all dimensions, and, if applicable, lead finish pre-plate specifications.

4.4 The type and part number of the molding and trim, form, singulate press to be used.

4.5 Singulation or off-load requirements.

4.6 *Expectations of Tooling Performance* — Tooling performance is not limited to the items listed in Section 5 and 6. Any other customer requirements, such as the limits on wire sweep, resin bleed or internal voiding, shall also be included with the purchase order.

4.7 Reference to this specification.

4.8 Vendor certification requirements.

5 Dimensions

5.1 All package dimensions should be specified in detail.

5.2 Ejector pin mark location from the package centerline. This should include ejector pin sizes, depths, and draft angles.

5.3 Pin 1 ID shape and location from the package center with respect to the lead frame Pin 1 location.

5.4 All critical radii (unspecified radii, often shown sharp on the drawing, may have the maximum radius shown in the table of Section 6).

5.5 Plastic stand-off shape and locations from the package center.

5.6 Lead spread (the distance between the outer edge of opposing leads).

5.7 Shoulder bend location and lead bend angle (optional).

5.8 Foot angle radius (maximum and minimum).

5.9 Foot length.

5.10 Lead length.

5.11 Shoulder width (maximum width should include protrusion).

6 Dimensional Tolerance Limits

These criteria, where applicable, apply only to opaque, plastic molded semiconductor packages. If an item is not mentioned in the following table, then the tolerances on the dimensions of that item follow the general tolerance limits stated on the drawing. Dimensions are in inches (millimeters) except as noted. Dimensions are to be verified per SEMI G48.

Table 1 Tolerance Limits

Dimension (Tolerance)	*PDIP*	*PLCC*	*SOIC*	*PQFP*	*PTAB*	*UNITS*
Package Length/Width ±	0.002 (0.05)	0.002 (0.05)	0.002 (0.05)	0.002 (0.05)	0.002 (0.05)	in. (mm)
Cavity Mismatch ±	0.002 (0.05)	0.002 (0.05)	0.002 (0.05)	0.002 (0.05)	0.002 (0.05)	in. (mm)
Cavity Overlap (Max.)	0.002 (0.05)	0.002 (0.05)	0.002 (0.05)	0.002 (0.05)	0.002 (0.05)	in. (mm)
Package/Leadframe Offset ±	0.002 (0.05)	0.002 (0.05)	0.002 (0.05)	0.002 (0.05)	0.001 (0.025)	in. (mm)
Plastic Body Thickness — Top and Bottom ±	0.002 (0.05)	0.002 (0.05)	0.002 (0.05)	0.002 (0.05)	0.001 (0.025)	in. (mm)
Surface Protrusions (Max.)	0.001 (0.025)	0.001 (0.025)	0.001 (0.025)	0.001 (0.025)	0.001 (0.025)	in. (mm)
Surface Intrusions — Depth (Max.)	0.001 (0.025)	0.001 (0.025)	0.001 (0.025)	0.001 (0.025)	0.001 (0.025)	in. (mm)
-X-Y Dimension (Max.)	0.010 (0.25)	0.010 (0.25)	0.010 (0.25)	0.010 (0.25)	0.005 (0.127)	in. (mm)
Ejector Pins — Intrusion only (Max.)	0.010 (0.25)	0.010 (0.25)	0.010 (0.25)	0.008 (0.20)	0.005 (0.127)	in. (mm)
Gate Feature — Intrusion only (Max.)	0.020 (0.50)	0.020 (0.50)	0.010 (0.25)	0.020 (0.50)	0.002 (0.05)	in. (mm)
Gate Feature — Protrusion only (Max.)	0.004 (0.10)	0.004 (0.10)	0.004 (0.10)	0.004 (0.10)	0.004 (0.10)	in. (mm)
Parting Line Protrusion — after deflash dambar removal (Max. per side)	0.006 (0.15)	0.006 (0.15)	0.006 (0.15)	0.006 (0.15)	0.005 (0.127)	in. (mm)
Parting Line Intrusion — Plastic (Max.)	0.010 (0.25)	0.010 (0.25)	0.005 (0.127)	0.010 (0.25)	0.005 (0.127)	in. (mm)
Parting Line Protrusion — after package singulation	0.006 (0.15)	0.006 (0.15)	0.006 (0.15)	0.006 (0.15)	0.005 (0.127)	in. (mm)
Warp Factor (Max.) — up to a Limit of	2.5% 0.003 (0.08)	2.5% 0.003 (0.08)	2.5% 0.003 (0.08)	2.5% 0.003 (0.08)	2.5% 0.003 (0.08)	in. (mm)
Draft Angles (Deg. ±)	1	1	1	1	1	
Package Radii — Noted Radii ±	0.0025 (0.06)	0.0025 (0.06)	0.0025 (0.06)	0.0025 (0.06)	* (*)	in. (mm)
Shown Sharp (Max.)	0.020 (0.50)	0.020 (0.50)	0.010 (0.25)	0.020 (0.50)	* (*)	in. (mm)
Lead Spread ±	0.025 (0.64)	0.010 (0.25)	0.010 (0.25)	0.005 (0.127)	* (*)	in. (mm)
Lead Bend Angles (Deg. ±)	-	5	2	2	2	
Shoulder Bend Location ±	0.010 (0.25)	0.010 (0.25)	0.005 (0.127)	0.005 (0.127)	* (*)	in. (mm)
Lead Sweep (from True position — Max.) (See Note 2)	0.007 (0.18)	0.004 (0.10)	0.004 (0.10)	0.003 (0.075)	0.003 (0.075)	in. (mm)
Foot Length ±	-	-	0.005 (0.127)	0.005 (.127)	* (*)	in. (mm)
Foot Radius ±	-	0.010 (0.25)	-	-	-	in. (mm)
Lead Length ±	0.005 (0.127)	-	-	-	-	in. (mm)
Foot Width ± incl. Leadframe Tolerance	-	-	0.002 (0.05)	0.002 (0.05)	* (*)	in. (mm)
Lead Coplanarity (Max.)	-	0.003 (0.08)	0.003 (0.08)	0.003 (0.08)	0.002** (0.05)	in. (mm)
Dambar Trim Protrusions (Max.)	0.003 (0.08)	0.003 (0.08)	0.003 (0.08)	0.003 (0.08)	0.003 (0.08)	in. (mm)
Dambar Trim Intrusions (Max.)	0.002 (0.05)	0.002 (0.05)	0.001 (0.025)	0.001 (0.025)	0.001 (0.025)	in. (mm)

* To be determined.

** If applicable.

NOTE 2: SOIC, J leaded packages have the plastic bodies and leads evaluated to the SOIC and PLCC tolerances as appropriate.

NOTE 3: Lead Sweep is not acceptable at buy-off.

7 Sampling Plan

A sampling plan and buy-off procedure to determine compliance to the requirements of Sections 5 and 6 and other relevant specifications shall be determined between vendor and customer.

8 Packaging and Marking

8.1 *Packaging* — Tooling must be packed in containers designed and constructed to provide protection against normal transportation damage risks and spillage. The container will offer protection from contamination and exposure to moisture. Tools may be coated with a suitable rust inhibitor as agreed between vendor and customer.

8.2 *Marking* — The following details shall be noted on the packing slip:

Vendor Part Number
Customer Part Number
Shipping Date
Customer P.O. Number
Shipment Items

SEMI G55-93
TEST METHOD FOR MEASUREMENT OF SILVER PLATING BRIGHTNESS

1 Preface

1.1 *Scope* — This method describes the standard method for measuring the brightness of silver plating on semiconductor leadframes.

Note: This method determines quantitative measures which are not related directly to the traditional "Dull," "Semi-Bright" and "Bright" descriptors for silver plating.

1.2 *Use* — This test may be used for process control and outgoing inspection at the supplier or by the user for incoming inspection.

2 Applicable Documents

2.1 *Related Documents*

2.1.1 *SEMI Specification*

SEMI G21 — Plating Integrated Circuit Leadframes

2.1.2 *JIS Specifications*[1]

JIS H8621 — Electroplated Coatings of Silver for Engineering Use

JIS Z8722 — Method of Measurement for Color of Reflecting or Transmitting Objects

JIS Z8741 — Method of Measurement for Specular Glossiness

2.1.3 *Military and Federal Specifications*[2]

QQ-S-365 — General Requirements for Electro-deposited Silver Plating

3 Significance

3.1 Brightness values indicate surface roughness for given plating conditions. Surface roughness affects the wettability of resinous die attach processes on leadframes. If the surface is too smooth, poor wetting may occur which results in low die share strength values.

3.2 Brightness variations may also affect the ability of the pattern recognition systems used on assembly equipment to recognize the set points.

1 JIS, 4-1-24 Akasaka Minato-ku Tokyo, Japan

2 Military Standards, Naval Publications and Form Center, 5801 Tabor Avenue, Philadelphia, PA 19120

4 Summary of Method

4.1 The method is based on the use of a GAM Densitometer. This method is chosen as the standard because of the small measurement area requirements and the high accuracy of the method for typical silver plating brightness used on leadframes.

This method is based on the measurement of the reflectance of light at 45° from a surface illuminated from a light source perpendicular to the surface. This value of Reflectance (R) gives a Density Value (D) based on the following formula:

$$D = \log 1/R$$

Density is a measure of the Brightness.

5 Interferences

5.1 *Surface Finish*

5.1.1 Brightness values depend on surface roughness. A rough surface shows a low brightness value when compared to a smooth surface. Variable plating conditions, such as the addition of brighteners to the plating solution, may give brightness results, which are not comparable for the acceptance of plated leadframes.

5.1.2 Scratches and other flaws in the surface will affect reflectance.

5.2 *Storage Time and Conditions*

5.2.1 Figure 1 shows the brightness results for leadframes subjected to indoor, atmospheric storage for an extended time. Results are shown for silver plating on copper alloy and Alloy 42 leadframes.

5.2.2 Leadframes shall be stored in conditions agreed between supplier and customer in order to limit atmospheric tarnishing, and brightness measurements shall be taken within an agreed time of delivery.

5.3 Degradation of the standards will affect calibration.

6 Equipment

6.1 GAM Densitometer or equivalent.

7 Sampling

7.1 A sampling plan shall be agreed between user and supplier.

8 Preparation of Samples

8.1 No special preparation requirements are necessary. Do not contaminate the samples by touching with bare hands.

9 Measurement Conditions

9.1 To confirm the lamp is on enough to measure the brightness values. (Lamp intensity is automatically calibrated.)

10 Equipment Setup and Calibration

10.1 *Equipment Setup*

10.1.1 Set up and turn on the equipment according to the manufacturer's instructions.

10.1.2 Allow at least 30 minutes for equipment stabilization before beginning measurements.

10.2 *Calibration*

10.2.1 Calibration shall be performed using standard black and white plates.

10.2.2 The equipment shall be recalibrated every 30 minutes.

11 Procedure

11.1 *Procedure*

11.1.1 Measurements shall be made close to the center of the die pad, if possible. In those situations where the die pad is not plated, the measurement site shall be agreed between user and supplier.

11.1.2 Measure all the selected samples according to the equipment manufacturer's instructions. Take three readings on each sample and obtain an average result for that sample.

11.2 *Results*

11.2.1 Brightness values shall be rounded to the first decimal place.

12 Report

The report, when used by a supplier to certify a customer's requirements or by the customer at incoming inspection shall contain, at least, the following information, other information which is reported shall be agreed between supplier and customer.

12.1 *Supplier's Lot Number and Date of Shipment*

12.2 *Test Conditions*

12.3 Results from Section 11. (SPC charting techniques may be used to monitor results for each leadframe type and plating requirement.)

13 Repeatability and Precision

13.1 *Repeatability*

13.1.1 Values for brightness based on use of a densitometer are repeatable within ± 0.003.

13.2 *Precision*

13.2.1 Precision for brightness values based on use of a densitometer is ± 0.015.

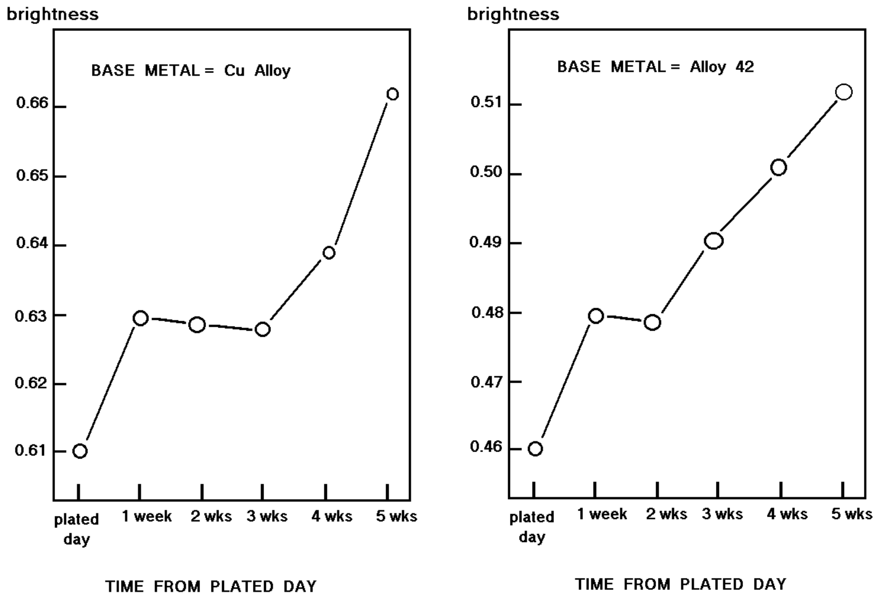

Figure 1
Changes of the Brightness Value as Time Goes by

Note: Specimens were kept in an office and directly exposed to the atmosphere.

Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI G56-93 (Reapproved 0302)
TEST METHOD FOR MEASUREMENT OF SILVER PLATING THICKNESS

This test method was technically approved by the Global Assembly and Packaging Committee and is the direct responsibility of the Japanese Assembly and Packaging Committee. Current edition approved by the Japanese Regional Standards Committee on November 26, 2001. Initially available at www.semi.org December 2001; to be published March 2002. Originally published in 1993.

1 Purpose

1.1 *Use* — This test may be used for process control and outgoing inspection at the supplier or by the customer for incoming inspection.

1.2 *Units* — This standard test method uses SI units.

2 Scope

2.1 This method describes the standard method for measuring the thickness of silver plating on semiconductor leadframes.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety health practices and determine the applicability or regulatory limitations prior to use.

3 Referenced Standards

3.1 *ASTM Specifications*[1]

ASTM B 568 — Measurement of Coating Thickness by X-Ray Spectrometry

4 Significance

4.1 The thickness of plating affects assembly processes such as wire bonding. If the plating is too thin, heat processes such as die attach cause the surface to become unbondable due to bleeding of the base material through the plating.

4.2 Schematic picture for measurement principles is shown in Figure 2.

5 Summary of Method

5.1 The method is based on the use of fluorescent X-rays. This method is chosen as the standard because of the small measurement area requirements, the high accuracy of the method for typical silver plating thicknesses used on leadframes, and the non-contact method.

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, Pennsylvania 19428-2959, USA. Telephone: 610.832.9585, Fax: 610.832.9555 Website: www.astm.org

6 Interferences

6.1 *Impurities in Plating*

6.1.1 Elements with atomic numbers between 42 (Molybdenum) and 52 (Tellurium) cause false readings.

6.2 *Measurement Time*

6.2.1 At small collimator diameters, the measurement time is no longer proportional to diameter. X-ray counting errors may occur for short measurement times.

6.3 Worn or abraded standards will affect calibration.

6.4 Base material variations will affect results. Standard samples and leadframes must have the same base material and plating system conditions for accurate results.

7 Equipment

7.1 Fluorescent X-ray spectrometer.

8 Sampling

8.1 A sampling plan shall be agreed between supplier and customer.

9 Preparation of Samples

9.1 No special preparation requirements are necessary.

10 Measurement Conditions

10.1 Collimator shall be set at 0.1 mm or 0.3 mm by agreement between user and supplier.

10.2 Measurement time shall be agreed between user and supplier.

11 Equipment Setup and Calibration

11.1 *Equipment Setup*

11.1.1 Set up the equipment according to the manufacturer's instructions.

11.1.2 Allow at least 30 minutes for equipment stabilization before beginning measurements.

11.2 *Calibration*

11.2.1 Calibration curves shall be generated using standard samples traceable to the National Institute of Standards and Technology or equivalent standards organization.

11.2.2 Calibration curves shall be generated after the equipment has stabilized per the manufacturer's instructions.

11.2.3 The equipment shall be recalibrated every 8 hours.

12 Procedure

12.1 *Procedure*

12.1.1 Measurements shall be made close to the center of the die pad, if possible. In those situations where the die pad is not plated, the measurement site shall be agreed between user and supplier.

12.1.2 Measure all the selected samples according to the equipment manufacturer's instructions.

NOTE: Refer to the equipment manufacturer's instructions and ASTM B 568 for safety conditions.

12.2 *Results*

12.2.1 Thicknesses shall be rounded to the first decimal place.

13 Report

The report when used by a supplier to certify a user's requirements or by the user at incoming inspection shall contain, at least, the following information. Other information which is reported shall be agreed between the user and supplier.

13.1 Supplier's Lot Number and Date of Shipment

13.2 Test Conditions

13.3 Results from Section 11. (SPC charting techniques may be used to monitor results for each leadframe type and plating requirement.)

14 Accuracy and Precision

14.1 *Accuracy*

14.1.1 Figure 1 shows curves of silver plating thickness measured by fluorescent X-Ray versus the percentage error in that measurement for two collimator settings for a constant measurement time.

SEMI G57-0302
GUIDE FOR STANDARDIZATION OF LEADFRAME TERMINOLOGY

This guide was technically approved by the Global Assembly and Packaging Committee and is the direct responsibility of the Japanese Assembly and Packaging Committee. Current edition approved by the Japanese Regional Standards Committee on November 26, 2001. Initially available on www.semi.org December 2001; to be puiblished March 2002. Originally published in 1993.

1 Preface

1.1 *Purpose* — This guideline defines standard terminologies for all the features of leadframes used in the production of semiconductor circuits.

1.2 *Significance* — Use of this guide in communications between customers and vendors can reduce the errors caused by the current use of different nomenclatures for the same feature of a leadframe.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their responsibility.

SEMI G58-94
SPECIFICATION FOR CERQUAD PACKAGE CONSTRUCTIONS

1 Preface

1.1 *Purpose* — This specification defines the acceptance criteria for Cerquad package components and includes requirements for the base, leadframe, window frame, cap and sealing glass materials.

1.2 *Scope* — This specification applies to all Cerquad packages which have a leadframe sandwich between two ceramic pieces — the base and the window frame — and sealed by glass, and a cap with a similar glass seal.

NOTE 1: The base, leadframe and window frame may be purchased as separate components or as a completed assembly.

1.3 *Units* — U.S. Customary (inch-pound) or metric (SI) units may be used at the customer's discretion. This specification uses U.S. Customary units as the prime unit.

NOTE 2: In the figures only U.S. Customary units are shown.

2 Applicable Documents

2.1 *Order of Precedence* — To avoid conflicts, the order of precedence when ordering package components shall be as follows:

SEMI G25 — Measuring the Resistance of Package Leads

Compilation of Terms

2.2.2 *JEDEC Specifications*[1]

Pub. No. 95 — Registered and Standard Outlines for Semiconductor Devices

2.2.3 *Military and Federal Specifications*[2]

MIL-STD-105 — Sampling Procedures and Tables for Inspection by Attributes

MIL-STD-883 — Test Methods and Procedures for Microelectronics

MIL-STD-1835 — Microcircuit Case Outlines

MIL-G-45204 — Gold Plating — Electrodeposited

MIL-M-38510 — General Specification for Microcircuits

3 Selected Definitions

3.1 *blister (bubble) metallization* — an enclosed locallized separation of the metallization from its base material (such as ceramic or another metallization layer component) that does not expose the underlying layer.

3.2 *burr* — an adherent fragment of parent material at a component edge. In leadframes, the metal burr, due to the stamping operation, may be in the horizontal or vertical direction to the surface. In ceramic packages, this type of characteristic is called a fin.

3.3 *camber (ceramic)* — arching of a nominally flat ceramic body.

3.4 *chip* — region of material missing from a component (e.g., ceramic from a package, or solder from a preform). The region does not progress completely through the component and is formed after the component is manufactured. Chip size is defined by its length, width and depth from a projection of the design planform. Also called chipout. (See Figure 1.)

3.5 *crack* — a cleavage or fracture that extends to the surface of a semiconductor package or solder preform. The crack may or may not pass through the entire thickness of the package or preform.

3.6 *critical seal area* — on a semiconductor package, the area bounded by the shortest nominal design distance from the largest cavity, usually the wire bond cavity, to the edge of the package or ceramic layer forming the seal area. (See Figure 2.)

3.7 *fin* — on a ceramic package or cap, a fine feathery-edged projection of parent ceramic material on the corner of the ceramic body.

1 JEDEC, 2001 Eye Street N.W., Washington, DC 20006.

2 Military Standards, Naval Publications and Form Center, 5801 Tabor Avenue, Philadelphia, PA 19120

3.8 *foreign material* — an adherent particle that is not parent material of the component. Adherence means that the particle cannot be removed by an air or nitrogen blast at 20 psi.

3.9 *glass flow* — on a semiconductor package or cap, the heating process which just removes all the screen printing mesh marks in the sealing glass when viewed at 10× magnification.

3.10 *glass void* — the absence of a sealing glass layer from a designated area.

3.11 *metallization void* — the absence of a clad, evaporated, plated or screen-printed metal layer or braze from a designated area.

3.12 *non-critical seal area* — on a semiconductor package that uses a lid, cap, or cover to effect the seal, the area of the sealing surface outside the critical sealing area. (See Figure 2.)

3.13 *overhang* — on a semiconductor package, the horizontal extension of the sealing glass past the vertical wall of a cavity cut into the ceramic layer on which the glass is printed. (See Figure 3.)

3.14 *peeling (flaking)* — any separation of a plated, vacuum deposited, or clad metal layer from the base metal of a leadframe, pin, heatsink, or seal ring, from an underplate, or from a refractory metal on a ceramic package. Peeling exposes the underlying metal.

3.15 *projection* — on a semiconductor package (plastic or ceramic), leadframe or preform, and irregularly raised portion of a surface indiginous to the parent material.

3.16 *pullback* — on a semiconductor package, the linear distance between the edge of a cavity cut into a ceramic layer and the first measureable glass or metallization layer interface coated onto the top surface of that layer. The total pullback may be the result of the high temperature processing required to manufacture the package or to coat the surface. It may also be the result of design considerations. (See Figure 3.)

3.17 *rundown* — on a semiconductor package, the linear distance from the upper surface of a ceramic cavity layer to the bottom point of the overhang into the cavity, of a sealing glass or metallization layer that has been screened onto that surface. (See Figure 3.)

4 Ordering Information

Purchase orders for cerquad packages and caps furnished to this specification shall include the following items:

4.1 Package description

4.2 Current drawing revision detailing

All dimensions

Type and color of ceramic

Type and thickness of sealant glass

Leadframe material type and design

Type and thickness of metallization in the lead bond area

Type and thickness of external lead plating, if applicable

Type and thickness of die attach metalization

4.3 Vendor certification requirements

4.4 Any additions to, or variations from, this specification

5 Dimensions

The component described in this specification shall produce packaged devices that conform to the outline dimesnions and lead numbering for Cerquad Package Constructions detailed in: JEDEC Publication 95; EIAJ; MILSTD1835. Package manufacturing tolerances shall be agreed between vendor and customer.

6 Materials

The definitions, defect criteria, and functional tests described in this specification relate to package components made with the following materials:

6.1 Base, Window Frame, and Cap

6.1.1 Material

6.1.1.1 *Alumina* — Content to be 90% minimum, or

6.1.1.2 *Beryllia* — Content to be agreed between vendor and customer.

6.1.2 *Color*

6.1.2.1 *Alumina* — Black, dark brown, or violet.

6.1.2.2 *Beryllia* — White.

6.2 *Sealant* — A solder glass suitable for hermetic sealing shall be specified.

6.3 *Die Attach Pad Metallization* — Gold or any other suitable material shall be specified.

6.4 *Leadframe*

6.4.1 *Base Material*

6.4.1.1 *Thickness* — Shall be specified.

6.4.1.2 *Composition* — Iron-Nickel-Cobalt alloy per MIL-M-38510, Type A or Iron-Nickel alloy per MIL-M-38510, Type B shall be specified.

6.4.2 *Finish* — Lead bond areas.

6.4.2.1 Metallization — Aluminum.

6.4.2.1.1 *Thickness* — 100 – 600 microinches (0.0025 – 0.015 mm).

6.4.2.1.2 *Coverage* — Total coverage for a distance of 0.030" (0.762mm) minimum as measured from the lead tip. Maximum length is defined by the lead bond cavity size.

6.4.2.1.3 *Composition* — 99.4% minimum for clad aluminum, 99.99% minimum for vapor deposited aluminum.

6.4.2.2 *Metallization* — Gold.

6.4.2.2.1 *Thickness* — 50 – 225 microinches (0.0013 – 0.0057mm).

6.4.2.2.2 *Coverage* — See paragraph 6.4.2.1.2.

6.4.2.2.3 *Composition* — See SEMI G21 and MIL-G-45204.

6.4.3 *Leadframe Finish* — External areas (if specified).

6.4.3.1 *Metallization* — Gold (see Section 6.4.2.2).

7 Defect Limits

The following defects shall be rejected if the limits shown are exceeded:

NOTE 3: The criteria apply to purchased pre-assemblies or, where applicable, to units assembled by the customer to process conditions agreed between vendor and customer.

7.1 *Ceramic Components*

7.1.1 *Cracks* — Not allowed.

7.1.2 *Chips* — See Figures 1 and 2.

7.1.2.1 *Corner Chips* — 0.030" (0.762 mm) × 0.030" (0.762 mm) × 25% of package element thickness.

7.1.2.2 *Edge Chips* — 0.060" (1.524 mm) × 0.030" (0.762 mm) × 25% of package element thickness.

7.1.2.3 *Critical Seal Area* — Chips must not reduce the critical seal path length, at any point, to less than one-half the nominal design dimension. No more than four chips are allowed in this area regardless of loss of seal length.

7.1.3 *Burrs, Projections (Fins), and Blisters*

7.1.3.1 *Base, Window Frame, and Cap* — 0.005" (0.127 mm) maximum allowable dimension or greater than 0.003" (0.076 mm) height.

7.1.3.2 *Die Attach Surface* — 0.001" (0.025 mm) maximum above the metallization surface excluding a zone, 0.010" (0.25 mm) wide, around the periphery of the cavity maximum allowable dimension is 0.005" (0.127 mm).

7.1.4 *Camber* — Shall be specified on the component drawing.

7.2 *Glass Sealant*

7.2.1 *Chips and Voids* — 0.010" (0.254 mm) maximum allowable dimension, with exposed or covered ceramic. No more than four chips or voids are allowed in the critical seal area. These defects must also meet the requirements of Table 1 in Section 7.2.2.4.

7.2.2 *Glass Misalignment (after glass flow)* — See Figure 3.

7.2.2.1 *Glass Overhang* — 0.15" (0.381 mm) maximum extension from the ceramic edge.

7.2.2.2 *External Rundown* — 50% of component thickness maximum.

7.2.2.3 *Rundown into Lead Bond Cavity* — 0.010" (0.254 mm) maximum extension from the top surface of the cavity.

7.2.2.4 *Pullback* — See Table 1.

Table 1 Maximum Allowable Pullback

External	0.015" (0.381 mm)
Internal	0.101" (0.254 mm)

NOTE 3: Glass pullback, at any point, shall not reduce the critical seal path width to less than one-half the designed width. (See Figure 2.)

7.2.2.5 *Foreign Material* — 0.020" (0.508 mm) maximum allowable dimension but 0.010" (0.254 mm) in the critical seal area, with no more than four sites allowed and a minimum separation of 0.030" (0.762 mm) between sites.

7.3 *Die Attach Cavity Metallization* — Excluding a 0.010" (0.254 mm) wide zone around the periphery of the cavity, the following criteria apply:

7.3.1 *Foreign Material, including Glass Splatters* — no more than four areas with 0.005" (0.13 mm) maximum dimension or greater than 0.001" (0.025 mm) height.

7.3.2 *Metallization Lumps* — No more than four allowed. If the metallization is Gold and eutectic Gold-Silicon die attach is to be used, then the lumps may not exceed 0.010" (0.254 mm) in diameter and 0.005" (0.127 mm) height. If eutectic bonding is not used, then the lumps will be treated as foreign material per Section 7.3.1

7.3.3 *Voids* — 0.005" (0.127 mm) maximum allowable dimension with no more than four allowed and a minimum separation of 0.030" (0.762 mm) between sites.

7.4 *Leadframe*

7.4.1 *Lead Bond Areas* — the minimum lead bond area on the lead tip is defined in Figure 4.

In these bond areas, the following defects are not allowed:

7.4.1.1 *Voids or Pits* — Exposure of base material with any dimension larger than 0.001" (0.0254 mm).

7.4.1.2 *Discoloration, Blistering, or Peeling of the Metallization*

7.4.1.3 *Scratches or Scrapes* — Any build-up of the metallization, or exposure of the base material.

7.4.1.4 *Foreign Material including Glass Splatter or Projections* — No more than four sites, each with a maximum dimension of 0.001" (0.0254 mm).

7.4.1.5 *Glass Wetting or Cracking* — Any lead finger which is not firmly embedded in the glass.

7.4.1.6 *Glass Pullback from the Lead Tip* — Greater than 0.010" (0.254 mm).

7.4.1.7 *Glass Bulge between Lead Fingers* — Greater than 0.005" (0.127 mm) height above the fingers except as agreed between vendor and customer for narrow pitch leads where this limit may cause wire bond interference problems.

7.4.1.8 *Lead Tip Coplanarity (Pre-assembled Bases, Leadframes, and Window Frames)* — Greater than 0.006" (0.15 mm) difference in the position of the top surface of the lead from highest lead to lowest lead.

7.4.1.9 *Lead Tip Pitch* — Greater than ± 0.002" (0.051 mm) variation from true position.

7.4.2 *Internal Lead Areas, excluding Lead Bond Areas* — In these areas, the following defects are not allowed:

7.4.2.1 *Burrs and Projections or Pits* — With a maximum dimension greater than 0.002" (0.0508 mm) in height or depth.

7.4.2.2 *Foreign Material (including Plating Discoloration)* — With a major dimension in the surface plane greater than 0.015" (0.381 mm) or exceeding 0.002" (0.0508 mm) in height.

7.4.2.3 *Voids which Expose Base Metal* — With a major dimension greater than 0.002" (0.0508 mm).

7.4.2.4 *Blistering or Peeling of Metallization*

7.4.2.5 Scratches and scrapes which cause metal build-up or expose base material.

7.4.3 *External Lead Areas*

NOTE 4: Non-functional areas of the leadframe, such as tie-bars, shall not be subjected to inspection.

7.4.3.1 Unplated Leads

NOTE 5: Plated leads shall also be required to pass these criteria.

7.4.3.1.1 *Scratches* — Causing loss of more than 25% of the leadframe thickness.

7.4.3.1.2 *Voids* — In violation of Section 7.4.3.1.1 or loss of more than 10% of the design width of a leadframe detail.

7.4.3.1.3 *Burrs* — In excess of 0.002" (0.051 mm) in height and 0.005" (0.127 mm) in the major dimension.

7.4.3.2 *Plated Leads*

7.4.3.2.1 *Scratches and Scrapes* — Exposure of base material or loss of plating integrity over 5% of the area of a lead finger.

7.4.3.2.2 *Voids* — Exposure of base material.

7.4.3.2.3 *Blistering or Peeling*

7.4.3.2.4 *Staining, Foreign Material, or Contamination* — In excess of 5% of the area of a lead finger.

7.4.4 *Lead Assembly*

7.4.4.1 *Lead Tip Overhang* — 0.010" (0.254 mm) maximum from the cavity wall, see Figure 5.

7.4.4.2 *Lead Misalignment* — 0.010" (0.254 mm) maximum, see Figure 6.

7.4.5 *Window Assembly Misalignment* — 0.015" (0.381 mm) maximum, see Figure 7.

8 Incoming Inspection and Functional Tests

8.1 *Incoming Inspection*

8.1.1 Dimensional inspection per Section 6.

8.1.2 Visual inspection per Section 7 at 10× magnification with vertical lighting.

8.1.3 *Metallization*

8.1.3.1 *Die Attach Metallization* — Thickness shall be measured by standard cross-sectioning without smearing or by X-Ray fluorescence.

8.1.3.2 *Lead Bond Metallization* — Thickness shall be measured by X-ray fluorescence.

8.1.3.3 *External Lead Plating (if applicable)*

8.1.3.3.1 *Thickness* — Shall be measured by X-ray fluorescence.

8.1.3.3.2 *Solderability* — Shall be tested per MIL-STD-883, Method 2003.

8.2 *Functional Testing*

NOTE 6: All procedures used to functionally test the components shall be agreed between user and supplier.

The sequence of functional testing shall be as shown in Figure 8.

8.2.1 *Die Attach*

8.2.1.1 *Visual Inspection*

Eutectic Bonding — Visually inspect the alloy wet-out after die attach. The minimum wet-out requirement shall be 100% of the die perimeter.

Silver Glass, Epoxy, or Polyimide Bonding — 100% die perimeter coverage shall be required.

NOTE 7: 100% coverage for resin bonding is not a function of package acceptability but is required to standardize die shear testing. The inability of the resins to wet the surface of the die attach area due to contamination is cause for rejection.

8.2.1.2 *Die Shear Test* — Perform destructive testing per MIL-STD-883, Method 2019.

NOTE 8: This test may also be performed after environmental testing. In the case of very large die, this test may not be appropriate to fully evaluate the package. In these cases, die sizes, agreed between vendor and customer, shall be used. Alternatively, die pull testing may be used by agreement between vendor and customer.

8.2.1.3 *Radiographic Inspection for Voids* — Perform inspection per MIL-STD-883, Method 2012.

8.2.1.4 *Ultrasonic Inspection for Voids, Delamination, and Cracks* — Perform inspection per MIL-STD-883, Method 2030.

8.2.2 *Wire Bond* — On wire bonds that meet the requirements of MIL-STD-883, Method 2010, perform destructive testing per MIL- STD-883, Method 2011, Test Condition D. Bonds which cause lifted metallization from the leadframe fingers shall also be cause for component rejection.

NOTE 9: This test shall be performed at pre-seal and post-seal.

8.2.3 *Seal*

8.2.3.1 *Visual Inspection* — The glass sealant appearance and flow shall be visually inspected for conformance to agreed process criteria.

8.2.3.2 *Cap Torque Test* — This test shall be performed per process agreement.

8.2.4 *Lead Finish* — Type A per MIL-M-38510 if required.

8.2.5 *Hermeticity* — This test shall be performed per MIL-STD-883, Method 1014, Test Condition A or B and C. The package must maintain hermetic integrity after each environmental test or sequence of tests.

8.2.6 *Environmental Testing* — Environmental evaluation shall include, but not be limited to, the following tests:

NOTE 10: The sequence of testing and the sample sizes for each sub-group shall be agreed between vendor and customer.

8.2.6.1 *Temperature Cycle* — Per MIL-STD-883, Method 1010, Condition C.

8.2.6.2 *Thermal Shock* — Per MIL-STD-883, Method 1011, Condition B.

8.2.6.3 *Vibration Fatigue* — Per MIL-STD-883, Method 2005, Test Condition B.

8.2.6.4 *Mechanical Shock* — Per MIL-STD-883, Method 2002, Test Condition B.

8.2.6.5 *Constant Acceleration* — Per MIL-STD-883, Method 2001, Test Condition D, "Y" axis only.

8.2.6.6 *Moisture Resistance* — Per MIL-STD-883, Method 1004.

8.2.6.7 *Additional Testing* — Additional tests performed at package qualification may include evaluation of electrical and thermal characteristics. These tests may be performed on a periodic basis to maintain package qualification.

These tests may include, but are not limited to, the following:

8.2.6.7.1 *Insulation Resistance* — Per MIL-STD-883, Method 1003, Test Condition as agreed between user and supplier.

8.2.6.7.2 *Lead Inductance* — Per SEMI Test Method G23.

8.2.6.7.3 *Lead-to-Lead Capacitance* — Per SEMI Test Method G24.

8.2.6.7.4 *Lead Resistance* — Per SEMI G25.

8.2.6.7.5 *Thermal Dissipation* — Per MIL-STD-883, Method 1012.

9 Sampling

The sampling plan, based on MIL-STD-105, shall be agreed between user and supplier.

10 Packaging and Marking

10.1 *Packaging* — The shipping containers and materials shall be suitability designed to provide the components with protection against normal transportation damage risks which include crushing and spillage, and exposure to moisture and other corrosive gases.

The packing materials must not cause particulate contamination on the components.

10.2 *Marking* — The shipping container shall be clearly marked with the following information:

Customer's Part Number

Customer's Purchase Order Number

Drawing Number (Customer's and Vendor's, if appropriate)

Quantity

Vendor Lot Number

Shipping date

SEMI G59-94 (Reapproved 0302)
TEST METHOD FOR MEASUREMENT OF IONIC CONTAMINATION ON LEADFRAME INTERLEAFING AND THE CONTAMINATION TRANSFERRED FROM THE INTERLEAFING TO THE LEADFRAMES

This specification was technically approved by the Global Assembling and Packaging Committee and is the direct responsibility of the Japanese Assembling and Packaging Committee. Current edition approved by the Japanese Regional Standards Committee on November 26, 2001. Initially available at www.semi.org December 2001; to be published March 2002. Originally published in 1994.

1 Purpose

1.1 This test method describes a procedure to determine the ionic contamination on leadframe interleafing and the contamination transferred from the interleafing to the leadframes using a water extraction method.

2 Scope

2.1 This test method is sensitive to the following ionic species:

Na^+, NH_4^+, K^+, Cl^-, NO_3^-, Br^-, SO_4^{2-}, PO_4^{3-}.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety health practices and determine the applicability or regulatory limitations prior to use.

3 Referenced Standards

3.1 *ASTM Specifications*[1]

D 4327 — Anions in Water by Ion Chromatography

D 1193 — Specification for Reagent Water

4 Terminology

4.1 *eluent* — The solvent used to carry the extracted ions through the ion exchange chromatograph.

4.2 *interleaf (for semiconductor leadframes)* — A paper or plastic film which is placed between layers of semiconductor leadframes strips to prevent tangling.

4.3 *regenerant* — A chemical solution containing the ions originally present in the chromatograph column prior to a test run, used to prepare the column for a new test.

4.4 *retention time* — The time required for a particular ion type to pass from the injection port to the detector. Retention time is characteristically different for each ion type.

4.5 *standard solution* — A solution containing a known concentration of the ion to be measured and used to calibrate the chromatograph.

5 Summary of Method

Ionic contamination is extracted in water at > 95°C for 30 ± 2 minutes. The contamination is quantitatively analyzed by ion type using ion chromatography, and the result is presented as nanograms/unit area.

6 Significance

6.1 Contamination on the interleaf may contribute to semiconductor device reliability problems by transference of the contamination to the leadframes.

6.2 The method may be used by leadframe manufacturers for the incoming inspection of the interleafing material, or by users at incoming inspection of the leadframes.

6.3 Correlation of device reliability results with interleaf contamination level measurements may lead to improved interleaf materials.

7 Interferences

7.1 The interleaf material and the leadframes must only be touched with cleaned tweezers or while wearing double-layer gloves with polyethylene outer gloves in order to avoid additional contamination.

8 Equipment

8.1 *Ion Chromatograph for Anion and Cation Analysis* — This equipment is to consist of a concentration pump, guard column, separator column, and a detector module.

The minimum sensitivity of the chromatograph for each ion type is defined in Table 1.

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, Pennsylvania 19428-2959, USA. Telephone: 610.832.9585, Fax: 610.832.9555 Website: www.astm.org

Table 1 Sensitivity of Ion Chromatograph

Ion		*Sensitivity(ng/mL)*
Cation	Na^+	0.2
	NH_4^+	0.5
	K^+	1.0
Anion	Cl^-	0.3
	PO_4^{3-}	2.0
	Br^-	1.0
	NO_3^-	1.0
	SO_4^{2-}	1.0

8.2 *Chart Recorder*

8.3 *Ion Extraction Vessels* — Polypropylene or polytetrafluoroethylene containers with sealing caps.

NOTE 1: The contamination level of these vessels must be less than one fifth (1/5) of the expected contamination level on the interleaf of leadframes when measured in a control test.

8.4 *Water Bath* — 300 mm L × 300 mmW × 200 mmH, filled with DI water, and capable of holding 95°C.

8.5 *Constant Temperature and Humidity Chamber*

8.6 *Volumetric Dispenser* — (e.g., Pipettes — 10 mL and 100 mL capacity).

8.7 *Quartz Flasks and Pipettes for Cation Standard Solutions* — 100, 250, 500, and 1000 mL capacity (flasks); 1, 10, and 25 mL capacity (pipettes).

8.8 *Borosilicate Glass Flasks and Pipettes for Anion Standard Solutions* — 100, 250, 500, and 1000 mL capacity (flasks); 1, 10, and 25 mL capacity (pipettes).

8.9 *Chemical Balance, Weighing Chemicals*

8.10 *Scissors, Tweezers, Spatula*

9 Reagents and Materials

9.1 Deionized water, resistivity ≥ 15 megohm centimeters at 25°C per ASTM D 1193.

9.2 Eluents and regenerants for specific chromatograph columns prepared per chromatograph equipment manufacturer's recommendations so that the water peak can be separated from the ionic peaks.

9.3 *Compounds Required for the Preparation of Standard Solutions*

9.3.1 *Cations* — NaCl, NH_4Cl, KCl.

9.3.2 *Anions* — NaCl, $Na_2HPO_4 \cdot 12H_2O$, NaBr, $NaNO_3$, K_2SO_4.

NOTE 2: All compounds must be reagent grade.

10 Sampling

10.1 *Sample Conditioning*

10.1.1 In case of measurement of ionic contamination transferred from the interleaves to the leadframes, select a stack of ten (10) leadframe strips with their nine (9) interleaves alternately, from the lot to be tested, and place them horizontally into a chamber at 85 ± 5°C, 85 ± 5% Relative Humidity for 24 hours.

10.2 *Sample Selection*

10.2.1 Recommended sample size of interleaf used in interleaf extraction test is 10,000 sq. mm.

10.2.2 In the extraction procedure, do not use the top or bottom leadframe strips in the stack.

NOTE 3: If a load is used to hold the stack together, it shall be recorded as part of the conditions of test.

NOTE 4: The leadframe/interleaf contact area shall be recorded. The vender and customer shall agree on the surface area of the leadframes.

11 Preparation of Standard Solutions

11.1 *Standard Solutions*

11.1.1 The single ingredient standard solutions of each ion (Na^+, NH_4^+, K^+, Cl^-, NO_3^-, Br^-, SO_4^{2-}, PO_4^{3-})are made by dissolving 1.000 g of each ion into 1.000 liter of DI water, respectively. The stored multi-ingredient standard solutions shown in Table 2 are then made from these single ingredient standard solutions by the dilution method.

Table 2 Concentration of Standard Solution for Calibration

Ion		*Mixed Standard Solution (µg/mL)*	*Standard Solution for Calibration(ng/mL)*		
			I	*II*	*III*
Cation	Na^+	10	5	10	20
	NH_4^+	10	5	10	20
	K^+	10	5	10	20
Anion	Cl^-	4	10	20	40
	PO_4^{3-}	10	25	50	100
	Br^-	4	10	20	40
	NO_3^-	4	10	20	40
	SO_4^{2-}	4	10	20	40

11.1.2 Cation and Anion standard solutions for calibration are made by diluting the stored multi-ingredient standard solutions as shown in Table 2.

11.1.3 Store the multi-ingredient standard solution and the calibration solutions in the correct flasks and label with the ion type and concentration.

NOTE 5: New Standard solutions for calibration are required every 24 hours. Ensure that the flasks are cleaned with water before refilling with a new solution.

11.2 *Calibration*

11.2.1 Set up the chromatograph and regenerate the columns according to the manufacturer's instructions (ASTM D 4327 provides further details).

11.2.2 Run the eluent through the chromatograph until a stable baseline chromatograph is obtained.

11.2.3 Select the injection volume recommended by the manufacturer for each ion type and inject it into the chromatograph. Record the chromatograph for each ion type, and make the calibration curve for each ion (ion concentration versus peak height or area).

NOTE 6: Peak height or area under the ion's characteristic curve is proportional to the concentration.

12 Procedure — Container Extraction Method

NOTE 7: The size of the extraction vessels depends on the expected volume of water and the leadframes. The vessels must be at least threequarters filled with water and leadframes.

NOTE 8: The vessels must be from the same manufacturing batch.

12.1 *Extraction Vessels* — Cleaning

12.1.1 Fill three vessels three-quarters of the way full in order to reduce the amount of air in the vessel and attach the caps.

12.1.2 Place the vessels in a water bath at > 95°C for 30 ± 2 minutes.

12.1.3 Remove the vessels from the bath and rinse out five (5) times with DI water.

12.2 *Interleaf Contamination Extraction*

12.2.1 Place the interleaf sample in one of the cleaned vessels.

NOTE 9: The interleafing may be cut in order to ease loading into the vessels.

12.2.2 Add 100 mL of DI water and cap the vessels. Place a similar amount of water into the other cleaned vessel and attach the cap.

NOTE 10: 100 mL is the recommended volume of water; however, the samples must be covered with water.

12.3 *Leadframe Contamination Extraction*

12.3.1 Place five (5) leadframe strips in one of the vessels cleaned per Section 12.1.

NOTE 11: The leadframes may be cut as required to ease entry into the vessel.

12.3.2 Cover with DI water and cap.

NOTE 12: 25 mL is the recommended volume of water for a small volume of leadframe samples, 100 mL for a large volume. The samples must be covered with water.

12.3.3 Place a similar volume of water in one of the vessels cleaned per Section 12.1.

12.4 *Extration*

12.4.1 Place the three (3) vessels into the water bath at T ≥ 95°C, for 30 ± 2 minutes.

12.4.2 Remove the vessels from the bath and allow to cool.

12.4.3 Remove the leadframes and interleafing material from their respective vessel and recap.

13 Measurements and Calculations

13.1 *Chromatograph Preparation and Calibration*

13.1.1 Prepare the chromatograph for operation by regenerating the columns according to the manufacturer's recommendations.

13.1.2 Run the eluent through the chromatograph until a stable baseline calibration is established.

13.2 *Testing*

13.2.1 Inject the recommended sample size of solution from the interleaf extraction into the chromatograph and obtain the chromatogram.

13.2.2 Repeat 13.1 and then inject the recommended sample size from the leadframe extraction and obtain the chromatogram.

13.2.3 Repeat 13.1 and then inject the recommended sample size from the water-only vessel and obtain the chromatogram of the background sample.

NOTE 13: The time from extraction to insertion of the sample into the chromatograph shall not exceed eight (8) hours.

13.3 *Results*

13.3.1 Sample concentrations are determined from the calibration curves for each ion type.

13.3.2 The surface concentration of ionic contaminants (SCIC) for each ion type is given by the following equation:

$$\text{SCIC}\left(\text{ng/cm}^2\right)= \frac{\left(\begin{matrix}\text{Sample}\\ \text{Concentration}\end{matrix} - \begin{matrix}\text{Background}\\ \text{Concentration}\end{matrix}\right) \times \begin{matrix}\text{Extraction}\\ \text{Volume(mL)}\end{matrix}}{\text{Total Interleaf(or Leadframe) Surface Area(cm}^2\text{)}}$$

14 Report

The report, when used by a vender to certify a user's requirement, or by a user at incoming inspection, shall, at least, contain the following information. Additional information shall be agreed between user and supplier.

14.1 Vendor's lot numbers for leadframes and interleaf material, and date of shipment.

14.2 Sample conditioning conditions.

14.3 Test conditions.

SEMI G52 — Standard Test Method for Measurement of Ionic Contamination on Semiconductor Leadframes (Proposed)

SEMI G60-94 (Reapproved 0302)
TEST METHOD FOR THE MEASUREMENT OF ELECTROSTATIC PROPERTIES OF SEMICONDUCTOR LEADFRAME INTERLEAFING MATERIALS

The test method was technically approved by the Global Assembly and Packaging Committee and is the direct responsibility of the Japanese Assembly and Packaging Committee. Current edition approved by the Japanese Regional Standards Committee on November 26, 2001. Initially available at www.semi.org on December 2001; to be published March 2002. Origianlly published in 1994.

1 Purpose

1.1 This test method describes a procedure to determine the electrostatic properties of interleaf materials in film or sheet form by measuring the magnitude and polarity of an induced charge and the time required for complete dissipation of the charge.

NOTE 1: The method is independent of volume or insulation resistivities.

2 Scope

2.1 This test method is suitable for all interleaf materials and may be used by vendors at outgoing inspection, or customers at incoming inspection.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety health practices and determine the applicability or regulatory limitations prior to use.

3 Referenced Standards

3.1 None

4 Terminology

4.1 *electrostatic properties* — For the purposes of this document, electrostatic properties are defined as the ability of a material, when grounded, to dissipate a charge induced onto the surface of that material.

4.2 *interleaf (for semiconductor leadframes)* — A paper or plastic film placed between layers of semiconductor leadframe strips to prevent transformation.

5 Summary of Method

The method involves charging the interleaf material to a high voltage and observing the time required for the charge to be dissipated using an electrometer.

6 Significance

6.1 This procedure evaluates the electrostatic build up and dissipation properties of the interleaf materials which may affect the reliability and efficiency of devices.

7 Interferences

7.1 The interleaf material and the leadframes must only be touched while wearing double-layer gloves with polyethylene outer gloves in order to avoid contamination which may change the electrostatic properties.

7.2 The test is not valid if the interleafing material is dusty.

8 Equipment

8.1 Aluminum panel measuring 127 mm × 76.2 mm × 3.2 mm (5" × 3" × 1/8").

8.2 High voltage source, 0 to 15 KV, positive and negative.

8.3 Electrometer with a full scale reading of 0.01, 0.1, 1.0, 10, and 100, or a recording oscilloscope with a response of 1 microsecond per division, or equivalent.

8.4 Fabricated electrostatic test chamber with electrostatic test unit, illustrated in Figure 1.

8.5 Single channel, pen type recorder with speeds of 12.7 mm, 25.4 mm, 50.8 mm, 101.6 mm, and 203.2 mm (0.5" , 1.0" , 2.0" , 4.0" , and 8.0") per minute and per second.

8.6 Four RG 114/U cables for connections between the detector and the electrometer and between the electrometer and the recorder. The nominal lengths of the cables are:

8.6.1 127 mm (5") for the connections between the detector and the output connector on the electrostatic test chamber.

8.6.2 863.6 mm (34") between the electrostatic test chamber and the electrometer exclusive of the connectors.

8.6.3 800.1 mm (31.5") between the electrometer and the recorder (2 required).

8.7 Three position control switch for connecting the test specimen to the high voltage source or the ground or neutral potential.

8.8 The equipment shall be assembled as illustrated in Figure 2.

9 Sampling

9.1 Sample size shall be agreed between user and supplier.

NOTE 2: The minimum sample size shall be three (3) per lot. Each specimen shall measure 127 mm × 76.2 mm (5" × 3").

9.2 Each specimen shall be free of defects such as holes, cracks, and tears.

NOTE 3: If the specimen is coated, the coating shall be continuous.

10 Sample Conditioning

10.1 Prior to testing, specimens shall be placed in the electrostatic test chamber for 24 hours at the following conditions.

Temperature: 23 ± 3° C

Relative Humidity: 50 ± 5%

11 Set-Up Procedure

11.1 Turn on all the equipment and allow to warm up as noted in the operations manuals.

11.2 *Electrometer*

11.2.1 Set "MULTIPLIER" switch to provide a half scale reading when the test voltage is applied.

11.2.2 Set the "OPERATE" switch at "ZERO CHECK".

11.2.3 Set meter to read positive charge.

11.3 Set the high voltage for 5KV positive output.

11.4 Mount the 127 mm × 76.2 mm × 3.2 mm (5" × 3" × 1/8") aluminum panel between the electrodes in the electrostatic test unit so that the detector head is directly over the center of the panel. Tighten the four wing nuts to secure the panel.

11.5 Set the recorder chart speed to 25.4 mm/min. (1" /min.).

11.6 Set "OPERATION" switch to "OPERATE".

11.7 Turn the three-position control switch to "HIGH VOLTAGE".

11.8 Verify that the reading on the recorder is identical to the meter reading. Adjust the recorder as necessary.

11.9 Turn the three-position switch to "GROUND" to remove the charge from the test panel.

11.10 When the electrometer meter reaches "ZERO", stop the recorder and set the "OPERATE" switch to "ZERO CHECK".

11.11 Repeat the calibration for a high voltage 5KV negative output.

12 Measurements and Calculations

12.1 Mount the specimens vertically between the electrodes and tighten the wing nuts to insure intimate contact between specimen and the electrodes.

12.2 Set chart recorder to 12.7 mm/sec. (0.5" /sec.) and turn on recorder.

12.3 Set electrometer meter switch to indicate "POSITIVE" or "NEGATIVE" charge depending on the high voltage to be applied.

12.4 Adjust the high voltage to 5KV positive or negative as desired.

12.5 Set "OPERATION" switch to "OPERATE".

12.6 Turn the three-position control switch to "HIGH VOLTAGE".

12.7 When the meter reaches a peak, indicating that the specimen has received its maximum charge, turn the three-position switch to "GROUND".

12.8 When the meter needle reaches "ZERO" or after 10 seconds which ever comes first, stop the recorder and move the "OPERATION" switch to "GROUND CHECK".

12.9 Charge each specimen three (3) times with both positive and negative charges. Allow the specimens to remain grounded for 10 minutes after each charging cycle to remove any residual charge on the specimen.

NOTE 4: If the interleaf material is non-homogenous, both surface shall be charged by reversing the faces of the specimen in contact with the electrodes.

12.10 Calculate the decay time, in seconds, by measuring the horizontal distance on the chart from the point where the specimen was grounded until the point where the needle reached "ZERO".

13 Report

The report, when used by a vendor to certify a customer's requirements, or by a customer at incoming inspection shall, at least, contain the following information. Additional information shall be agreed between user and supplier.

13.1 Interleaf material.

13.2 Vendor's lot number for the interleaf material, and date of shipment.

13.3 Sample conditioning conditions.

13.4 Test conditions if different from this test method.

13.5 The surface charged.

13.6 Results from Section 11 indicating the calculated decay time for each specimen in the sample for both the positive and negative charges and the acceptance (or rejection) at incoming inspection. SPC charting techniques may be used to monitor results.

NOTE 5: Acceptance/rejection limits shall be agreed between user and supplier.

SEMI G61-94
SPECIFICATION FOR COFIRED CERAMIC PACKAGES

1 Preface

1.1 *Purpose* — This specification defines the materials and acceptance criteria for high-temperature, cofired ceramic packages.

1.2 *Scope* — The criteria detailed in this specifiication apply to the following package outlines registered with, or specified by JEDEC (see Publication 95), EIAJ, or MIL-STD-1835 specifications:

Chip Carriers (Leadless or Leaded)

Dual-in-Line Packages (Sidebrazed)

Flat Packs (Top or Bottom Brazed)

Grid Arrays (Land/Ball or Pin)

NOTE 1: Packages not meeting these specifications may also use the criteria as appropriate.

This document consolidates the criteria for all cofired packages so that package amnufacturing and inspection may be simplified and costs reduced.

1.3 *Units* — U.S. Customary (inch-pound) or metric (SI) units may be used at the customer's discretion. This specification uses U.S. Customary units as the prime unit. In the drawings, only U.S. Customary units are detailed.

2 Applicable Documents

2.1 *Order of Precedence* — To avoid conflicts, the order of precedence when ordering packages shall be as follows:

3 Definition of Terms

3.1 *blister (bubble) ceramic* — an enclosed, localized separation within or between the layers of a ceramic package that does not expose an underlying layer of ceramic or metallization.

3.2 *blister (bubble) metallization* — an enclosed, localized separation of a metallization layer from its base material (such as ceramic or another metal layer) that does not expose the underlying layer.

3.3 *braze* — in semiconductor packages, an alloy used to attach pins, leads, seal rings and heat sinks/studs to the package.

3.4 *burr* — an adherent fragment of parent material at a component edge. In leadframes, the metal burr, due to the stamping operation, may be in the horizontal or vertical direction to the surface. In ceramic packages, this type of characteristic is called a fin.

3.5 *castellations* — metallized semi-circular channels on chip carrier edges which provide contact between internal package metallization traces and the external test pads. These castellations provide for improved solder fillets during attachment to a circuit board (see Figure 1).

3.6 *cavity-down packages* — packages where the die surface faces the mounting board. (See Figure 2 for the pin grid array packages in the cavity-down configuration. It is more usual to refer to the chip carrier mounting surfaces as the seating planes. In this cavity orientation, the seating plane is Seating Plane 2 per JEDEC JC-11.)

3.7 *cavity-up packages* — packages where the die surface faces away from the mounting board (see Figure 2 or Seating Plane 1 for chip carriers).

3.8 *chip* — region of material missing from a component (e.g., ceramic from a package, or solder from a preform). The region does not progress completely through the component and is formed after the component is manufactured. Chip size is defined by its length, width and depth from a projection of the design platform. Also called chipout (see Figure 1).

3.9 *co-fired* — in the manufacturing of some types of ceramic packages, the technology used to join together various ceramic layers and metallization patterns screened onto those layers by simultaneous firing at high temperature.

3.10 *contact pad* — in a leadless chip carrier or land grid array, the metallized areas on the bottom of the package that provide contact point between the internal leads and connecting external circuitry. They are also used for electrical test pads.

3.11 *crack* — a cleavage or fracture that extends to the surface of a semiconductor package or solder preform. The crack may or may not pass through the entire thickness of the package or preform.

3.12 *critical seal area (ceramic)* — on a semiconductor package, the area bounded by the shortest nominal design distance from the largest cavity, usually the wire bond cavity, to the edge of the package or ceramic layer forming the seal area.

3.13 *critical seal area* — metallization or metal ring — The entire area of the seal ring; it applies to plated refractory metal or a metal ring.

3.14 *critical seal path (ceramic)* — on a semiconductor package, the shortest nominal design distance from the largest cavity, usually the wire bond cavity, to the edge of the package or ceramic layer forming the seal area.

3.15 *delamination* — in a co-fired ceramic package, chip carrier, pin grid array, etc., the separation of one ceramic layer from another.

3.16 *element (packaging)* — part of a semiconductor package feature (e.g., package leads have braze paddle/stand-off and contact elements, pins have the nail head/braze area and contact elements).

3.17 *fin* — on a ceramic package or cap, a fine feathery-edged projection of parent ceramic material on the corner of the ceramic body.

3.18 *flatness* — in a ceramic package or leadframe, the allowable deviation of a surface from a defined reference plane. The tolerance zone is defined by two parallel planes within which the surface must lie.

3.19 *foreign material* — an adherent particle that is not parent material of the component. Adherence means that the particle cannot be removed by an air or nitrogen blast at 20 psi.

3.20 *heat exchange area* — a metallized region on one major surface of the package to which heat sinks may be attached by brazing, soldering, or adhesive resin.

3.21 *layer* — on a cofired ceramic package, the body is made from layers of ceramic or metallized ceramic. The layers are defined by their functionality, and several ceramic layers may be described as comprising one functional layer if all are common in plan-form and function (e.g., die attach cavity) (see Figure 4).

3.22 *lead offset* — in brazed lead ceramic packages, the variation in position of the centerline of the lead with reference to the centerline of the braze pad to which it is mounted.

3.23 *lead sweep* — lead movement, measured with respect to a datum, perpendicular to the top or bottom of the package that passes through the designed mid-point of the lead where the lead is attached to the package (e.g., side-brazed laminates), or where the lead exits the package body (e.g., plastic dual-in-line packages). The movement is viewed from the side of the package, not the ends.

3.24 *lead-to-lead separation* — the distance between adjacent leads when measured from their centerlines at the point of connection to the package.

3.25 *lead tweeze* — lead movement, measured with respect to a datum, perpendicular to the top or bottom of the package that passes through the designed mid-point of the lead where the lead is attached to the package (e.g., side-brazed laminates), or where the lead exits the package body (e.g., plastic dual-in-line packages). The movement is viewed from the ends of the package, not the side and the lead movement is from the edges of the package in toward the centerline of the package.

3.26 *metallization void* — the absence of a clad, evaporated, plated or screen-printed metal layer or braze from a designated area. Also called metal or plating void.

3.27 *peeling (flaking)* — any separation of a plated, vacuum-deposited, or clad metal layer from the base metal of a leadframe, pin heatsink, or seal ring, from an underplate, or from a refractory metal on a ceramic package. Peeling exposes the underlying metal.

3.28 *pin offset* — the variation in position from the centerline of the pin to the centerline of the braze pad to which it is mounted.

3.29 *pin sweep* — pin movement, measured with respect to a datum, perpendicular to the top or bottom of the package that passes through the designed mid-point of pin where the pin is attached to the package (e.g., pin grid arrays). The movement is viewed form the side of the package, not the ends.

3.30 *pin-to-pin separation* — the distance between adjacent pins when measured from their centerlines at the point of connection to the package.

3.31 *pin tweeze* — pin movement, measured with respect to a datum, perpendicular to the top or bottom of the package that passes through the designed mid-point of pin where the pin is attached to the package (e.g., pin grid arrays). The movement is viewed form the ends of the package, not the side and the pin movement is from the edges of the package in toward the centerline of the package.

3.32 *pit* — in semiconductor packages, plastic or ceramic, or in the leadframes, a shallow depression or crater. The bottom of the depression must be visible in order for the term to apply. A pit is formed during component manufacture (see Figure 3).

3.33 *porous surface* — an uncompacted ceramic surface often showing fine pits.

3.34 *projection* — on a semiconductor package (plastic or ceramic), leadframe or preform, and irregularly raised portion of a surface indigenous to the parent material.

3.35 *pullback* — on a semiconductor package, the linear distance between the edge of a cavity cut into a ceramic layer and the first measurable glass or metallization layer interface coated onto the top surface of that layer. The total pullback may be the result of the high temperature processing required to manufacture the package or to coat the surface. It may also be the result of design considerations (see Figure 5).

3.36 *rundown* — on a semiconductor package, the linear distance from the upper surface of a ceramic cavity layer to the bottom point of the overhang into the cavity, of a sealing glass or metallization layer that has been screened onto that surface (see Figure 5).

3.37 *scrape* — the irregular removal of a deposited layer from a base material by a shearing action from another surface such that the base material is exposed over an extended area. It can also apply to the removal of surface layers from a material. The material removed from the scraped area may build up at the edges of the scrape. The deposited layer may be a metal or glass.

3.38 *seal area* — on a semiconductor package, the area designated for sealing a cover or lid to a cofired ceramic package, or a cap to a cer-DIP or cer-pack base. In the case of a co-fired ceramic package the seal area may be either bare ceramic for glass sealing or a metallized area for solder sealing. The metallized seal area may be a plating over refractory metallization or a metal ring, usually iron-nickel-cobalt or iron-nickel alloys, brazed to the refractory metal.

3.39 *seating plane* — in plug-in packages such as dual-in-line (side-brazed or cer-DIP) or pin grid arrays, the plane defined by the three lowest stand-off features on the lead or pins as measured from the bottom of the package, or in the absence of these features, by the package base or mounting plane (see Figure 6). The features, such as shoulders or projections, hold the package off the circuit board to which it is mounted. This gap allows solder flux and residues to be cleaned after soldering the device and, in some cases, to allow for sufficient cooling air flow around the device. A prescribed force is used to hold the device in the mounting holes when the seating plane is to be measured.

3.40 *side-to-side misalignment* — the offset of the center lines of corresponding leads or pins from one side of the package to another side.

3.41 *stand-off* — the separation between the base plane and the seating plane that is created by physical features that are usually formed into the pins or leads (see Figure 6). The features may also be called stand-offs.

3.42 *TIR* — total Indicator Reading.

4 Ordering Information

Purchase orders for packages furnished to this specification shall include the following items.

4.1 *Current Drawing Revision Detailing*

4.1.1 All dimensions and tolerances per ANSI Y14.5M practices.

4.1.2 Internal metallization trace pattern.

4.1.3 Type and color of ceramic.

4.1.4 *Pin or Lead Material and Hardness* — If applicable.

4.1.5 *Heat Sink/Stud Material and Hardness* — If applicable.

4.1.6 Type, hardness, and thickness of plating in the die and wire bond areas and contact pads.

4.1.7 *Type, Hardness, and Thickness of Plating on Pins or Leads and Heat Sink/Stud* — If applicable.

4.1.8 *Lead Number 1 Identification* — (See Figure 7.)

4.2 Vendor certification requirements.

4.3 Reference to this specification.

4.4 Any additions to, or variations from, this specification.

4.5 Quantity.

5 Dimensions

Package dimensions and lead numbering shall conform to the outlines registered with or specified by JEDEC (see Publication 95), EIAJ or MIL-STD-1835, as appropriate. Package manufacturing tolerances shall be agreed between user and supplier.

6 Materials

The definitions, defect criteria, and functional tests described in this specification relate to packages made with the following materials.

6.1 *Ceramic Body*

6.1.1 *Material* — Alumina, beryllia, aluminum nitride, or mullite as specified on the package drawing.

6.1.1.1 *Alumina* — Content to be 90% minimum.

6.1.1.2 *Beryllia* — Content to be 99% minimum. (Packages shall be marked BeO.)

6.1.1.3 *Aluminum nitride* — Content to be agreed between user and supplier.

6.1.1.4 *Mullite* — Content to be agreed between user and supplier.

6.1.2 *Color*

6.1.2.1 *Alumina* — White, black, dark brown, or violet.

6.1.2.2 *Beryllia* — White.

6.1.2.3 *Aluminum Nitride* — White, black, dark brown, or violet.

6.1.2.4 *Mullite* — White, black, dark brown, or violet.

6.2 Die Attach Pad, Wire Bond Fingers, Contact Pads, and Circuit Trace Metallization

6.2.1 *Base Material* — Refractory tungsten per MIL-M-38510, Type C. Thickness shall be 0.0003" (0.0076 mm) minimum.

6.2.2 *Finish* — Shall meet the requirements of MIL-M-38510.

6.2.2.1 *Nickel Under Plate (if specified)* — Shall be per QQ-N-290A. Thickness shall be 50 – 350 micro-inches (0.0013 – 0.0089 mm).

6.2.2.2 *Gold Plate* — Shall be per MIL-G-45204, Type III. Thickness shall be 50 – 225 micro-inches (0.0013 – 0.005715 mm).

6.3 *Pins, Leads, and Seal Ring*

6.3.1 *Base Material* — Iron-nickel-cobalt alloy per MIL-M-38150, Type A or iron-nickel alloy per MIL-M-38150, Type B shall be specified on the package drawing.

6.3.2 *Hardness* — 70–85 Rockwell-B for Type A material, 60–80 Rockwell-B for Type B material.

6.3.3 *Finish* — Shall meet the requirements of MIL-M-38510 per Section 6.2.2.

6.4 *Heat Sink/Stud*

6.4.1 *Material*

6.4.1.1 *Heat Sink* — (Forming at least part of the package base and the die attach area) tungsten-copper (composition to be defined on the drawing), iron-nickel (cobalt) alloy per Section 6.3.1 or molybdenum as specified on the package drawing.

6.4.1.2 *Stud* — (Brazed to a metallized area of the ceramic base layer or the heatsink of the package) — copper, tungsten-copper, or kovar as specified on the package drawing.

6.4.2 *Hardness* — Shall be specified on the drawing by agreement between user and supplier.

6.4.3 *Finish* — Shall meet the requirements of MIL-M-38510 per Section 6.2.2.

6.5 *Braze*

6.5.1 *Material* — Silver/copper (72%/28%) or equivalent shall meet the general requirements of MIL-STD-7883.

6.5.2 *Finish* — Shall meet the requirements of MIL-M-38510 per Section 6.2.2.

7 Defect Limits

Inspection shall be carried out at 10× magnification with vertical lighting.

The following conditions are cause for rejection.

7.1 *Ceramic Components*

7.1.1 *Cracks* — Any crack is cause for rejection.

7.1.2 *Chips* — See Figure 3.

7.1.2.1 *Corner Chips* — Chip sizes exceeding the limits shown in Table 1. No chip may be deeper than 50% of the package element (the ceramic functional layer) thickness.

Table 1

Package Dimension inch (mm)	*Maximum Corner Chip Dimensions (either direction) inch (mm)*
≤0.250 (≤6.35)	0.020 (0.508)
>0.250 – ≤0.500 (>6.35 – ≤12.7)	0.040 (1.016)
>0.500 – ≤1.000 (>12.7 – ≤25.4)	0.080 (2.032)
>1.000 (>25.4)	0.100 (2.54)

7.1.2.2 *Edge Chips* — Chip sizes exceeding the limits shown in Table 2. No chip may be deeper than 50% of the package element (the ceramic functional layer) thickness.

Table 2

Package Dimension in which Chip Occurs inch (mm)	*Maximum Chip Length and Width inch (mm)*
≤0.250 (≤6.35)	0.020 (0.508)
>0.250 – ≤0.500 (>6.35 – ≤12.7)	0.040 (1.016)
>0.500 – ≤1.000 (>12.7 – ≤25.4)	0.080 (2.032)
>1.000 (>25.4)	0.100 (2.54)

7.1.2.3 Chips exposing a buried metallized area excluding the plating buses which are exposed when packages are separated from the manufacturing arrays.

7.1.2.4 *Critical Seal Area (ceramic)* — Any chip reducing the critical seal path length, at any point, by more than 30% of the nominal design dimension.

No more than three chips, each of which reduces the seal path length by more than 10% but less than 30%, are allowed in this area. Each chip's length shall not exceed the limits shown in Table 3.

Table 3

Seal Ring Dimension in which Chip Occurs inch (mm)	*Maximum Chip Length inch (mm)*
≤0.250 (≤6.35)	0.020 (0.508)
>0.250 – ≤0.500 (>6.35 – ≤12.7)	0.040 (1.016)
>0.500 – ≤1.000 (>12.7 – ≤25.4)	0.080 (2.032)
>1.000 (>25.4)	0.100 (2.54)

7.1.3 *Ceramic Projections* — (bumps and blisters)

7.1.3.1 *Body (non-critical surfaces)* — Any projection, including fins, exceeding 0.005" (0.127 mm) in height, or exceeding 0.002" (0.051 mm) in height and with a surface dimension greater than 0.010" (0.254 mm).

NOTE 2: On surface mount packages, the bottom of the package shall not have any projections exceeding 0.002" (0.051 mm) in height.

7.1.3.2 *Die Attach Areas* — (bare ceramic or screen printed metal area) — Excluding a zone, 0.015" (0.381 mm) wide, around the periphery of the cavity, any projection exceeding 0.001" (0.025 mm) in height or a surface dimension of 0.010" (0.254 mm).

NOTE 3: Exclusion zones around the periphery of die attach areas may be wider on larger packages or when a metal heat sink or stud is brazed to the package and forms the die attach area (Section 7.3). The width of such zones shall be defined on the package drawing by agreement between user and supplier. This note applies to all criteria affecting die attach areas.

7.1.3.3 *Critical Seal Area (printed metal area)* — Any projection exceeding 0.001" (0.025 mm) in height or with a surface dimension exceeding 0.010" (0.254 mm) or 30% of the critical seal length, whichever is the larger.

7.1.3.4 *Critical Seal Area (bare ceramic)* — Any projection exceeding 0.001" (0.025 mm) in height or with a surface dimension exceeding 0.010" (0.254 mm) or 30% of the critical seal path, whichever is the larger.

7.1.3.5 *Wire Bond Fingers* — Any projection in the critical area defined in Figure 8 exceeding 0.0005" (0.0127 mm) in height or a surface dimension of 0.004" (0.102 mm).

7.1.3.6 *Solder Pads, Contact Pads, and Heat Exchange Areas* — Any projection exceeding 0.002" (0.051 mm) in height above the pad, or a surface dimension of 0.010" (0.254 mm).

NOTE 4: Castellation areas of chip carriers are excluded from these criteria because of the manufacturing process. (Layer misalignments, separation techniques, etc. may cause projections which do not affect package quality.

7.1.4 *Pits*

7.1.4.1 *Body (non-critical surfaces)* — Pits exceeding 0.003" (0.076 mm) in depth or a surface dimension of 0.020" (0.508 mm).

7.1.4.2 *Die Attach Areas (bare ceramic or screen printed metal area)* — Excluding a zone, 0.015" (0.381 mm) wide, around the periphery of the cavity, pits exceeding 0.001" (0.025 mm) depth below the surface or a surface dimension of 0.010" (0.254 mm). Acceptable pits shall not cover more than 10% of the surface area.

NOTE 5: Ceramic pits in metallized areas may be covered by metallization, but remain cause for rejection.

NOTE 6: Pits with a depth not exceeding 0.0005" (0.0127 mm) are not rejectable.

7.1.4.3 *Critical Seal Area (bare ceramic or metallized area)* — Pits exceeding 0.001" (.025 mm) depth below the ceramic surface or a surface dimension of 0.010" (0.254 mm). No more than three acceptable pits allowed in this area with a minimum separation of 0.030" (0.762 mm) required between sites. The seal ring width must not be reduced by more than 30% of its designed width at any point. Acceptable pits shall not cover more than 10% of the critical seal area.

7.1.4.4 *Wire Bond Fingers* — Any pit in the critical area defined in Figure 8 exceeding 0.0005" (0.0127 mm) in depth, or any pit exeeding 0.004" (0.102 mm) in a surface dimension.

7.1.4.5 *Solder Pads, Contact Pads, and Heat Exchange Areas* — Pits exceeding 0.002" (0.051 mm) depth below the pad or a surface dimension of 0.010" (0.254 mm). Acceptable pits shall not cover more than 10% of the surface area.

NOTE 7: Pits with a depth not exceeding 0.0005" (0.0127 mm) are not included in this evaluation, regardless of surface dimension.

NOTE 8: Pits in castellation areas are exluded from these criteria because of the manufacturing process.

7.1.5 *Flatness (Camber)*

7.1.5.1 *Package Flatness* — Flatness variation exceeding 0.004 inch/inch (0.004 mm/mm), with a minimum camber specification of 0.002" (0.051 mm).

7.1.5.2 *Die Attach Area Flatness* — Any flatness variations exceeding the limits shown in Table 4.

NOTE 9: These criteria apply to any die attach area ceramic, metallized ceramic, or a heat sink which forms the die attach area.

Table 4

Die Attach Area (Major Dimension) inch (mm)	*Flatness (Maximum Allowable TIR) inch (mm)*
0.750 (# 19.05)	0.002 (0.051)
>0.750 (>19.05)	0.003 inch (0.0762 mm)

7.1.5.3 *Seal Area Flatness* — See Table 5.

NOTE 10: These criteria apply to packages with bare ceramic, metallized ceramic, or a metal ring. Flatness to be measured per SEMI G6.

Table 5

Seal Ring (Major Dimension) inch (mm)	*Flatness (Maximum Allowable TIR) inch (mm)*
≤0.500 (≤12.7)	0.002 (0.051)
>0.500 (>12.7)	0.003 (0.076)

7.1.6 *Delamination* — Any evidence of delamination between ceramic layers which exceeds 0.030" (0.762 mm), in a major dimension, in more than two locations.

NOTE 11: Inspection may also be made by scanning acoustic microscopy per MIL-STD-883, Method 2030, if internal delamination is suspected. Vendor and customer shall agree that such inspection is necessary for package integrity.

7.1.7 *Foreign Material* — Any particulate or film-like foreign material exceeding 0.005" (0.127 mm) height or a surface dimension of 0.020" (0.508 mm). No more than three acceptable sites allowed on the body with a minimum separation of 0.030" (0.762 mm) required between sites.

7.1.8 *Porous Surface* — Packages showing surface poro-sity per ASTM F 109 shall be subjected to seal testing per Section 8.2.4 to verify acceptance.

NOTE 12: Surface porosity may cause inconsistent results at hermeticity testing. Packages which show porosity and fail a hermeticity test may be evaluated per ASTM E 165 to verify the acceptance. Inspection may also be made by scanning acoustic microscopy per MIL-STD-883, Method 2030.

7.2 *Metallized Areas on Ceramic*

7.2.1 *Plating Voids* — (Includes voids due to refractory metal printing defects.)

7.2.1.1 *Die Attach Areas* — Excluding a 0.015" (0.381 mm) wide zone around the periphery of the cavity, voids exceeding a surface dimension of 0.020" (0.508 mm). Acceptable voids shall not cover more than 10% of the surface area.

7.2.1.2 *Seal Ring Area* — Voids exceeding a surface dimension of 0.020" (0.508 mm). The seal ring width must not be reduced by more than 30% of its designed width at any point. Acceptable voids shall not cover more than 10% of the seal ring area.

7.2.1.3 *Wire Bond Fingers* — Any void in the critical area defined in Figure 8.

7.2.1.4 *Internal Lead Traces* — Any void which reduces the width of the trace by more than 50% of its designed width.

NOTE 13: X-ray radiography per MIL-STD-883, Method 2012, or scanning acoustic microscopy per MIL-STD-883, Method 2030, may be used to verify the integrity of covered traces.

NOTE 14: Pits are not cause for rejection, providing any metallization loss does not exceed the 50% criteria.

7.2.1.5 *Solder Pads/Castellations or Contact Pads* — Voids with any dimension larger than 0.010" (0.254 mm) or loss of area exceeding 25%. The connection between a solder pad and the castellation must not be reduced in width by more than 50% of its design width.

7.2.1.6 *Braze Pads* — Voids with any dimension larger than 0.010" (0.254 mm). No more than one visible, acceptable void per pad is allowable after pin or lead attachment.

7.2.1.7 *Heat Exchange Area* — Voids with a surface dimension larger than 0.020" (0.508 mm). Acceptable voids shall not cover more than 10% of the heat exchange area.

7.2.2 *Scratches and Scrapes*

7.2.2.1 *Die Attach Areas* — Excluding a 0.015" (0.381 mm) wide zone around the periphery of the cavity, any buildup of material exceeding 0.001" (0.0254 mm) in height or exposing base metallization (refractory or underplate) so that void criteria are violated.

7.2.2.2 *Seal Ring Areas* — Any buildup of material exceeding 0.001" (0.0254 mm) in height or exposing base metallization (refractory or underplate) so that void criteria are violated.

7.2.2.3 *Wire Bond Fingers* — Any scratch in the critical area defined in Figure 8, which causes metallization build-up exceeding 0.0005" (0.0127 mm) in height or a surface dimension of 0.004" (0.102 mm). In non-critical lead trace areas, any scratch which exposes base metallization (refractory or underplate) across more than 50% of the designed trace width.

7.2.2.4 *Solder Pads/Castellations* — Any scratch which isolates more than 25% of a pad from the castellation by exposure of refractory metallization. Scrapes must not violate the void criteria of Section 7.2.1.5.

7.2.2.5 *Heat Exchange Areas* — Any scratches and scrapes which cause void criteria to be violated (see Section 7.2.1.7).

7.2.3 *Blistering or Peeling of the Metallization* — Any evidence of blistering or peeling.

NOTE 15: Discoloration is not a defect unless a functional test is affected (e.g., wire bonding) (see Section 8).

7.2.4 *Plating Nodules* — Nodules exceeding the criteria for bumps in Sections 7.1.3.2, 7.1.3.3, 7.1.3.4, and 7.1.3.5.

7.2.5 *Refractory Metallization* — Printing and firing defects (see Figure 5).

7.2.5.1 *Metallized Seal Ring Rundown* — Rundown exceeding 25% of the adjacent internal cavity's depth.

7.2.5.2 *Wire Bond Finger Rundown* — Rundown exceeding 25% of the cavity depth or 0.005" (0.127 mm), whichever is smaller.

7.2.5.3 *Wire Bond Finger Pullback* — Pullback exceeding 0.006" (0.152 mm).

7.2.5.4 *Metallization Pattern Separation* — A reduction in pattern separation by more than 50% of the designed separation.

NOTE 16: Pattern separation for chip carrier solder pads may be further specified by agreement between supplier and customer to avoid solder shorting during circuit board assembly.

7.2.5.5 *Seal Ring Pullback* — Pullback exceeding 0.006" (0.152 mm) from the nominal design location from both the cavity and package edge directions.

7.2.6 *Foreign Material* — (Particulate or film-like)

7.2.6.1 *Die Attach Areas (includes bare ceramic die attach areas)* — Excluding a 0.015" (0.381 mm) wide zone around the periphery of the cavity, any foreign material exceeding 0.001" (0.0254 mm) in height or a surface dimension of 0.020" (0.508 mm). Acceptable foreign material shall not cover more than 5% of the die attach area.

7.2.6.2 *Seal Area (includes bare ceramic die attach areas)* — Any foreign material exceeding 0.001" (0.0254 mm) in height or a surface dimension of 0.020" (0.508 mm). The seal ring width shall not be reduced by more than 30% of its width at any point by foreign material. Acceptable foreign material shall not cover more than a total of 10% of the seal ring area.

7.2.6.3 *Wire Bond Fingers* — Any foreign material in the critical area defined in Figure 8.

7.2.6.4 *Solder Pads/Castellations, Contact Pads, and Heat Exchange Areas* — Any foreign material exceeding 0.001" (0.0254 mm) in height or a surface dimension of 0.010" (0.254 mm). Acceptable foreign material shall not cover more than 10% of these areas.

7.3 *Pins, Leads, Metal Seal Rings, or Heat Sinks/Studs*

NOTE 17: If the heat sink is used as the die attach area, the following conditions must not violate the criteria in Sections 7.1 and 7.2 for defect size and accumulation.

7.3.1 *Plating Voids* — Voids, exposing base material or underplate, with any dimension exceeding 0.005" (0.127 mm) or with a total accumulation of more than 5% of the surface area of any pin, lead, heat sink/stud, or braze. If the total accumulation of voids is less than 5% of the area of an element of a package feature, a sample of the defective units shall be submitted to Salt Atmosphere testing per MIL-STD-883, Method 1009, Condition A. If the sample passes this test, the lot shall be acceptable

Voids, exposing base material or underplate, in the seal ring plating violating the criteria of Section 7.2.

7.3.2 *Scratches or Scrapes* — Any buildup of the metallization, or exposure of the base material or underplate, which exceeds 5% of the surface area of any pin, lead, heat sink/stud, or braze. If the total accumulation of scratches or scrapes is less than 5% of the area of an element of the package feature, a sample of the defective units shall be submitted to salt atmosphere testing per MIL-STD-883, Method 1009, Condition A. If the sample passes this test, the lot shall be acceptable.

7.3.3 *Nicks*

7.3.3.1 Any nick in pins or leads exceeding 10% of the diameter or thickness.

7.3.3.2 Any nick in the heat sink/stud which violates void or pit criteria.

7.3.3.3 Any nicks in the seal ring area which violate the criteria of Section 7.2.

7.3.4 *Pits*

7.3.4.1 *External Surfaces* — Any pit exceeding 0.005" (0.127 mm) in depth or 0.010" (0.0254 mm) in a surface dimension.

Metal seal rings shall have no more than three acceptable sites, and there must be a minimum separation of 0.030" (0.762 mm) required between acceptable sites. The width of the seal ring must not be reduced by more than 30% of its designed width at any point. Acceptable pits shall not cover more than 5% of heat sinks/studs. Acceptable pits shall not cover more than 25% of pins or leads.

7.3.4.2 *Internal Surfaces* (Die Attach Areas) — Any pit exceeding 0.001" (0.0254 mm) in depth and violating the plating void criteria per Section 7.2.1.1.

7.3.5 *Plating Nodules* — Any nodule exceeding the criteria for burrs in Section 7.3.7.

7.3.6 *Foreign Material* — Any particulate or film-like (stain) foreign material exceeding 0.001" (0.025 mm) in height or an accumulation of sites in excess of 5% of the surface area of any pin, lead, or heat sink/stud. Any foreign material reducing the separation between two active metal areas to less than 50% of the designed separation.

7.3.7 *Burrs* — Any burr in excess of 0.002" (0.051 mm) height or 0.005" (0.127 mm) in a major dimension.

7.3.8 *Blistering or Peeling* — Any evidence of blistering or peeling.

NOTE 18: Blistering and peeling on a lead frame tie-bar are acceptable. Discoloration is not cause for rejection unless a functional test is affected (e.g., solderability).

7.3.9 *Corrosion* — Any evidence of corrosion.

7.3.10 *Braze*

7.3.10.1 *Excessive Braze* — Any separation between active metal areas which is reduced to less than 50% of the designed separation.

Any excessive braze which interferes with the intended use of the package (e.g., excessive braze height which prevents proper seating of a package).

7.3.10.2 *Insufficient Fillet* — Pin, lead, heat sink/stud braze areas where more than 25% of the periphery is not covered by the braze fillet, provided the voided areas do not extend under the brazed component.

Any pin, lead, heat sink/stud braze areas where more than 5% of the periphery is not covered by the braze fillet and any voids extend under the brazed element.

7.3.11 *Mechanical Damage*

7.3.11.1 Broken, Kinked, or Missing Pins or Leads

7.3.11.2 *Twist* — Any pin or lead twisted by more than 10° from the untwisted condition.

7.3.11.3 *Pin or Lead Sweep* — Any location of the tip of the pin or lead exceeding 0.010" (0.0254 mm) away from the vertical (or horizontal, for flat packs) datum passing through the mid-point of the pin or lead at the point of brazing to the contact pad.

7.3.11.4 *Pin or Lead Tweeze* — Any location of the tip of the pin or lead exceeding 0.010" (0.0254 mm) away from the vertical datum passing through the mid-point of the pin or lead at the point of brazing to the contact pad.

7.3.11.5 *Threads* — Any damage to the threads on studs.

7.4 *Package Construction*

7.4.1 *Pins and Leads* — Location.

7.4.1.1 *Pin or Lead Offset* — Any offset from the pin or lead true position exceeding 0.005" (0.127 mm).

7.4.1.2 *Lead-to-Lead or Pin-to-Pin Separation* — Any separation exceeding 10% of the designed separation, up to an allowable maximum of 0.010" (0.254 mm).

7.4.1.3 *Side-to-Side Misalignment* — Any misalignment exceeding the limits shown in Table 6.

Table 6

Package Type	*Maximum Allowable Side-to-Side Misalignment inch (mm)*
Dual-in-Line	0.010 (0.254)
Flat Packs	0.005 (0.127)
Leaded Chip Carriers	0.005 (0.127)
Pin Grid Arrays	0.005 (0.127)

NOTE 19: During inspection, the combination of offset, separation, and side-to-side misalignment shall also meet limits agreed between user and supplier.

7.4.2 *Ceramic Layer Misalignment* — Any misalignment between layers exceeding 0.005" (0.127 mm) in either the X or Y planes.

7.4.3 *Metallization Alignment to Ceramic* — Any misalignment exceeding the limits defined on the package drawing.

8 Incoming Inspection and Functional Tests

8.1 *Incoming Inspection* — Packages shall be inspected in the following sequence.

8.1.1 Dimensional inspection to the requirements of Section 5. All dimensions shall be measured by techniques agreed between supplier and customer except as follows:

8.1.1.1 Seal ring flatness shall be measured per SEMI G6.

8.1.2 Visual inspection per Section 7.

8.1.3 *Metallization* — Plating.

8.1.3.1 *Thickness* — Shall be measured by x-ray fluorescence per ASTM B 568. The location of the areas to be measured, which include die and wire bond and seal ring areas, the tolerance and acceptable standards shall be agreed between user and supplier.

8.1.3.2 *Temperature Resistance* — Shall be evaluated per SEMI G8.

8.1.3.3 *Plating Hardness* — Die and wire bond and seal ring areas — shall be measured per ASTM B 578 to limits defined by MIL-G-45204 if specified by agreement between vendor and customer.

8.1.3.4 *Pin, Lead, Solder Castellation, or Solder Pad Solderability* — Shall be tested per SEMI G35.

8.1.4 *Pin, Lead, Seal Ring, or Heat Sink/Stud Hardness* — Shall be measured per ASTM E 18 if specified by agreement between vendor and customer.

8.1.5 *Pin or Lead Integrity* — Shall be evaluated per MIL-STD-883, Method 2004.

NOTE 20: After each test, the plating shall be evaluated for continuity per SEMI G35.

8.1.5.1 *Tension* — Per Test Condition A except as shown in Table 7.

Table 7

Pin/Lead Dimension inches (mm)	*Minimum Tension lbs (kg)*
Round Pin	
0.008 (0.203)	1.0 (0.455)
0.018 (0.457)	10.0 (4.55)
Rectangular Lead	
0.018×0.010 (0.457×0.254)	10.0 (4.55)

8.1.5.2 *Fatigue* — Per Test Condition B2 if specified by agreement between user and supplier.

8.1.5.3 *Torque* — Per Test Condition C1 if specified by agreement between user and supplier.

8.1.5.4 *Solder Pad Adhesion* — Per Test Condition D if specified by agreement between vendor and customer.

8.1.6 *Stud Integrity* — Shall be evaluated per MIL-STD-883, Method 2004, Test Condition C2. Torque to be agreed between user and supplier.

8.1.7 *Heat Sink Integrity* — Test shall be agreed between user and supplier.

8.2 *Functional Testing* — The sequence of functional testing shall be as shown in Figure 9. (Packages shall be sequentially subjected to all tests.)

NOTE 21: All procedures used to functionally test the components shall be agreed between user and supplier.

8.2.1 *Die Attach*

8.2.1.1 *Visual Inspection*

Eutectic Bonding — Visually inspect the alloy wet-out after die attach. The minimum wet-out requirement shall be 100% of the die perimeter.

Silver Glass, Epoxy, or Polyimide Bonding — 100% die perimeter coverage shall be required.

NOTE 22: 100% coverage for resin bonding is not a function of package acceptability but is required to standardize die testing. The inability of the resins to wet the surface of the die attach area due to contamination is cause for rejection.

8.2.1.2 *Die Shear Test* — Perform destructive testing per MIL-STD-883, Method 2019.

8.2.1.3 *Radiographic Inspection for Voids* — Perform inspection per MIL-STD-883, Method 2012.

8.2.1.4 *Ultrasonic Inspection for Voids, Delamination, and Cracks* — Perform inspection per MIL-STD-883, Method 2030.

NOTE 23: These tests may also be performed after environmental testing. In the case of very large die, the die shear test may not be appropriate to fully evaluate the package. In these cases, die sizes or alternative tests agreed between user and supplier shall be used. In the case of eutectic die attach, the results from these tests may also be indicative of poor functionality of the gold die attach metallization.

8.2.2 *Wire Bond* — On wire bonds that meet the requirements of MIL-STD-883, Method 2010, perform destructive testing per MIL-STD-883, Method 2011, Test Condition D. Bonds which cause lifted metallization from the wire bond fingers or which fail the pull test criteria shall be cause for package rejection.

NOTE 24: The inspection level A or B, for Method 2010, shall be agreed between vendor and customer. The pull test shall be performed at pre-seal and post-seal. The minimum average pull strength, standard deviation, and acceptable rupture modes shall be agreed between user and supplier.

8.2.3 *Seal*

8.2.3.1 *Visual Inspection* — Criteria shall be agreed between user and supplier.

8.2.4 *Hermeticity* — Performed per MIL-STD-883, Method 1014, Test Condition A or B and C, the package must maintain hermetic integrity after each environmental test or sequence of tests.

NOTE 25: Internal water-vapor content may also be measured per MIL-STD-883, Method 1018.

8.2.5 *Environmental Testing* — Environmental evaluation shall include, but not be limited to, the following tests.

NOTE 26: The sequence of testing and the sample sizes for each sub-group shall be agreed between user and supplier. Packages with heat sinks or studs require the environmental tests to be evaluated on an individual basis. The materials, form factor, and method of attachment may not be suitable for the tests noted due to the generation of overly severe stresses. The appropriate tests shall be agreed between user and supplier.

8.2.5.1 *Temperature Cycle* — Per MIL-STD-883, Method 1010, Condition C on packages without a heat sink or stud, or Condition B for packages with a heat sink or stud.

8.2.5.2 *Thermal Shock* — Per MIL-STD-883, Method 1011, Condition C.

8.2.5.3 *Vibration Fatigue* — Per MIL-STD-883, Method 2005, Test Condition B for packages without a heatsink.

8.2.5.4 *Mechanical Shock* — Per MIL-STD-883, Method 2002, Test Condition B for packages without a heatsink.

8.2.5.5 *Constant Acceleration* — Per MIL-STD-883, Method 2001, Test Condition A for packages without a heatsink.

NOTE 27: Y1 axis only for cavity-up packages, Y2 axis only for cavity-down packages.

8.2.5.6 *Additional Testing* — Additional tests performed during package qualification may include evaluation of electrical and thermal characteristics, corrosion resistance, and alpha particle emissions. These tests may be performed on a periodic basis to maintain package qualification. These tests may include, but are not limited to, the following.

Insulation Resistance — Per MIL-STD-883, Method 1003, to test conditions agreed between user and supplier.

Lead Inductance — Per SEMI Test Method G23 or using an impedance analyzer by a method agreed between user and supplier.

Lead-to-Lead Capacitance — Per SEMI Test Method G24.

Lead Resistance — Per SEMI Test Method G25.

Junction-to-Case Thermal Resistance — Per SEMI G30 or a wind tunnel method agreed between user and supplier.

Alpha particle emission shall be tested by a method and to limits agreed between user and supplier.

Salt Atmosphere (Corrosion) Testing — Per MIL-STD-883, Method 1009, Condition A.

9 Sampling

The sampling plans shall be agreed between user and supplier.

10 Packaging and Packing List

10.1 *Packaging* — The shipping containers and materials shall be suitably designed to provide the components with protection against normal transportation damage risks which include crushing, abrasion, and spillage and exposure to moisture and other corrosive gases.

The inner packing materials must not cause particulate contamination on the components and shall be clean-room compatible as defined by the user. The components, in packing trays, shall be sealed in a vacuum bag with a dessicant.

10.2 *Packing List*

10.2.1 *Internal Packages* — Each internal package shall be marked as follows.

Customer's Part Number

Customer's Purchase Order Number

Drawing Number (user's and supplier's, if appropriate)

Supplier Shipping Lot Number

Quantity

Date of Manufacture

10.2.2 *External Packages* — The packing list, located on the outside of the container, shall provide the following information.

User's Part Number

User's Purchase Order Number

Quantity

Shipping Date

Any specific instructions for receiving dock personnel.

11 Certification

11.1 Upon request of the user in the contract or purchase order, a supplier's certification that the product was manufactured and tested in accordance with this specification, together with a report of the test results, shall be furnished at the time of shipment. However, if the user does perform inspection and tests on a certified shipment and the product fails to meet the requirements, the product is subject to rejection.

11.2 If the user and supplier agree, the product may be certified as capable of meeting this specification. In this context, capable of meeting signifies that the vendor is not required to perform all the inspections and tests. However, if the user does perform inspection and tests on such product and it fails to meet the requirements, the product is subject to rejection.

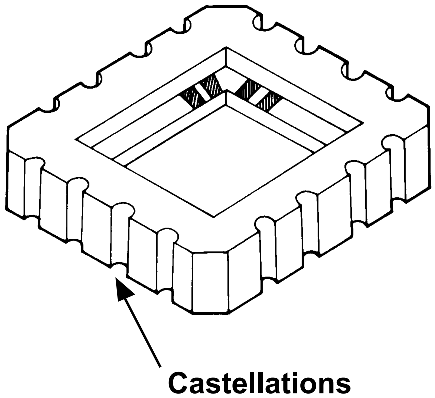

Figure 1

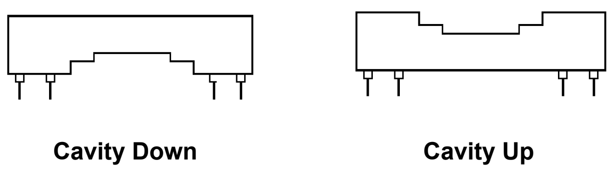

Figure 2

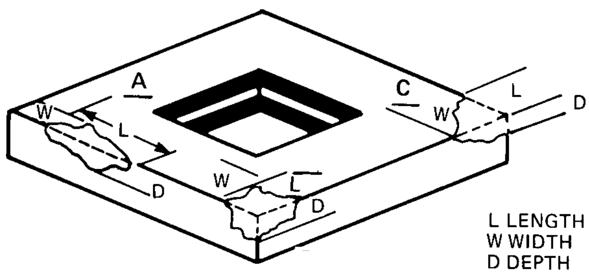

Figure 3

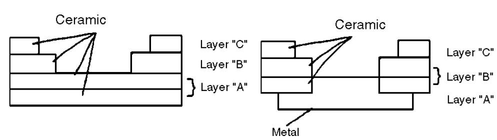

Functional layers shall be designated by letter beginning with "A" as the layer nearest the terminal insertion plane. Layers, regardless of function, shall be designated by succeeding letter (B, C, D, etc.) as they are progressively remote from the insertion plane. Functional layers may be manufactured from two or more ceramic layers.

Figure 4

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their responsibility.

SEMI G62-95 (Reapproved 0302)
TEST METHOD FOR SILVER PLATING QUALITY

This test method was technically appoved by the Global Physical Interfaces and Carriers Committee and is the direct responsibility of the Japanese Physical Interfaces and Carriers Committee. Current edition approved by the Japanese Regional Standard Committee on November 26, 2001. Initially available at www.semi.org December 2001; to be published March 2002. Originally published in 1995.

1 Purpose

1.1 This test method describes procedures to determine silver plating quality.

2 Scope

2.1 These methods apply to silver plating on leadframes for plastic packages. Applicable plating styles are listed in Table 1.

Table 1 Plating Style

Plating Style	*Description*
Overall Plating	Plating covers the whole leadframe area. In some situations, the leadframe may be quoted as having overall plating, but the rails will be unplated in order to save plating costs.
Ring Plating	Only inner leads plated on top surface.
Ring-Tip Plating	Only wire bonding areas of inner leads plated.
Spot Plating	Only die pad and inner leads plated on top surface.
Spot Plating (both sides)	Die pad and inner leads are plated on both the top and bottom surfaces of the leadframe.
Tip Plating	Only die pad and wire bonding areas plated.
W-Ring Plating	Only inner leads plated on top surface and around die pad.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety health practices and determine the applicability or regulatory limitations prior to use.

3 Units

3.1 This test method uses SI units.

4 Referenced Standards

4.1 *SEMI Documents*

SEMI G55 — Test Method for Measurement of Silver Plating Brightness

SEMI G56 — Test Method for Measurement of Silver Plating Thickness

4.2 *Military Specifications*[1]

MIL-M-38510 — General Specification for Microcircuits

5 Terminology

5.1 *area variation* — The variation between the defined and actual plated area.

NOTE 1: Oversized plating area is an area larger than the specified area. Undersized plating area is an area smaller than the specified area.

5.2 *attached silver particles* — Small silver particles which are attached to the normal plated surface during the plating process.

5.3 *bleed out, back side* — Plating on the back of leadframe caused by seepage of the plating solution beyond the mask.

5.4 *bleed out, side* — Plating occurring on the sides of leadframe features.

5.5 *bleed out, surface* — Seepage of the plating solution beyond the mask on the top surface of the leadframe increasing the plated area.

5.6 *bleed out, epoxy* — The separation of the resin component from the filled epoxy resin such that it creeps on the die pad beyond the outline of resin fillet.

5.7 *blister (metal)* — An enclosed, localized separation of the plating metallization from the base material or from another layer of plating which can be depressed with a sharp instrument.

NOTE 2: This may occur during plating or after application of heat.

5.8 *burnt deposit* — Plated surface is too rough.

5.9 *contamination* — Three-dimensional alien material adhering to a surface.

5.10 *corrosion* — Electrochemical degradation of the material usually exhibited by discoloration such as rust.

1 Available through the Naval Publications and Forms Center, 5801 Tabor Avenue, Philadelphia, PA 19120-5099, USA. Telephone: 215.697.3321

5.11 *discoloration* — Any change in the color of the metallization, as detected by the naked eye. This may occur on as plated or after application of heat.

5.12 *excessive plating* — Plating exists outside the specified area.

5.13 *foreign material* — An adherent particle other than parent material of the component.

NOTE 3: Adherent denotes inability to be removed with an air or nitrogen blow-off at 20 psi.

5.14 *incomplete plating* — Plating is missing from any part of the designated area.

5.15 *leadframe top surface* — The active side of the leadframe, the surface used for die attach and wire bonding.

5.16 *nodule (of plated particle)* — A protrusion or lump of plating material above the plated surface.

5.17 *plating nonuniformity* — The lack of consistency of brightness of silver as plated, or after the application of heat. These changes in the plated grain structure causes the inconsistency.

5.18 *peeling* — The lifting of metallization from a surface.

5.19 *pit (of plating)* — A hole or depression extending below the surface of the plating.

5.20 *scratch (on plating)* — A surface deformation which exposes underlying metallization.

5.21 *spot-sparing* — A stain-like discoloration occurring after the application of heat.

5.22 *step plating* — Plateau-like plating having more than one level.

5.23 *spot plating misalignment* — The variation between the defined and actual center lines of the plated area.

5.24 *tape test* — A metallization layer adhesion test technique using adhesive tape to apply a peel force to the layer. This test may be applied on plated material or after the application of heat.

5.25 *whisker* — A plating metal burr-like filament attached to the surface of the plating.

6 Summary of Method

6.1 Various test methods are described or referenced to determine silver plating quality for the following items:

- Plating Area
- Plating Thickness
- Plating Brightness
- Visual Inspection
- Functional Test

7 Interferences

7.1 Avoid contaminating the silver plated surface prior to performing the test. Such contamination may affect visual appearance and die attach, wire bonding, and solderability functional tests.

8 Equipment

8.1 GAM densitometer or equivalent

8.2 X-Ray Fluorescence

8.3 Microscope with a 40× maximum magnification.

8.4 Heater block, hot plate or oven (furnace)

9 Sampling

9.1 Sampling plans shall be agreed between user and supplier.

10 Test Sequence

10.1 When the test methods are used at incoming inspection, the sequence of tests shall be as follows:

10.1.1 *Plating Area* — See Section 11.1.

10.1.2 *Plating Thickness* — See Section 11.2.

10.1.3 *Plating Brightness* — See Section 11.3.

10.1.4 *Visual Inspection* — See Section 11.4.

10.1.5 *Heat Test* — See Section 11.5.

10.1.6 *Functional Test* — See Section 11.6.

11 Test Procedures

11.1 *Plating Area*

11.1.1 Measurements may be made by using a glass scale, shadow scope, or microscope.

11.1.2 Measurement items are listed below:

11.1.2.1 Area variation

11.1.2.2 Spot plating misalignment

11.2 *Plating Thickness*

11.2.1 Plating thickness shall be measured at a point on the inner lead or the center point of the die pad.

NOTE 4: The location of the thickness test shall be agreed between user and supplier.

11.2.2 Thickness measurements may be made using X-Ray Fluorescence per SEMI G56.

11.3 *Plating Brightness*

11.3.1 Plating brightness shall be measured at the center point of the die pad.

NOTE 5: If leadframes do not have a plated die pad, the location of the brightness test shall be agreed between user and supplier.

Plating brightness shall be measured using a GAM densitometer or equivalent per SEMI G55.

11.4 *Visual Inspection*

11.4.1 Visual inspection may be performed with the naked eye or a microscope with up to 40× maximum magnification, as required to confirm results.

11.4.2 Visual inspection shall be performed before and after functional testing.

11.4.3 Inspection items are listed below.

1. attached silver particles
2. blister
3. bleed-out
4. burnt deposit
5. contamination
6. corrosion
7. discoloration
8. excessive plating
9. foreign material
10. incomplete plating
11. nodule
12. plating nonuniformity
13. peeling
14. pit
15. scratch
16. spot-sparing
17. step plating
18. whisker

11.5 *Heat Test*

11.5.1 *Conditions* — The conditions in Table 2 shall be used to heat test silver plated leadframes.

Table 2 Heat Test Condition

Leadframe Material	*Bake Temperature*	*Bake Time (min.)*
Iron-Nickel Alloy per MIL-STD-38510, Type B	400° C ± 5° C	3 min. + 10 (-0) sec.
Cu Alloy	300° C ± 5° C	3 min. + 10 (-0) sec.
Taped Leadframe	275° C ± 5° C	3 min. + 10 (-0) sec.

11.5.2 The test may be carried out on a heater block or hot plate, or in an oven (furnace). The heat capacity of the test equipment must be sufficient to avoid temperature swings outside the specified limits when the test is started.

NOTE 6: When using a heater block or hot plate, ensure that air flow does not affect the bake temperature.

11.6 *Functional Test*

11.6.1 *Epoxy Die Bonding* — Processes and test procedures shall be agreed upon between user and supplier.

11.6.2 *Gold Wire Bonding* — Processes and test procedures shall be agreed upon between user and supplier.

11.6.3 *Solderability* — Processes and test procedures shall be agreed upon between user and supplier.

SEMI G63-95 (Reapproved 0302)
TEST METHOD FOR MEASUREMENT OF DIE SHEAR STRENGTH

This test method was technically approved by the Global Assembly and Packaging Committee and is the direct responsibility of the Japanese Assembly and Packaging Committee. Current edition approved by the Japanese Regional Standards Committee on November 26, 2001. Initially available at www.semi.org December 2001; to be published March 2002. Originally published in 1995.

1 Purpose

1.1 The purpose of this test method is to determine procedures for die shear strength testing.

2 Scope

2.1 This test method shall be used for the measurement of the die shear strength when die attach paste is used to bond a die to a leadframe bond pad.

2.2 This test method shall be used for quality control and development at die attach paste suppliers and for incoming inspection and selection of the die attach paste at die attach paste users.

2.3 This test method can be applicable to die attach material besides paste material and may be used to evaluate leadframe bond pad quality.

2.4 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety health practices and determine the applicability or regulatory limitations prior to use.

3 Referenced Standards

3.1 *Military Specification*[1]

MIL-STD-883 — Method 2019, Die Shear Strength

4 Terminology

4.1 *die* — Semiconductor device or an imitation.

4.2 *die attach* — Bond die and substrate such as leadframe pad.

4.3 *die contact tool* — Tool for applying load to the die for shearing.

4.4 *dispense* — Deal out paste.

4.5 *fillet* — Height and shape of die attach paste in contact with or surrounding the die kerf.

4.6 *shear* — Have forced completely in X-Y direction.

5 Summary of Method

5.1 This method is based on measuring the shear strength between die and leadframe pad bonded by die attach paste using die shear tester.

6 Equipment

6.1 *Die Shear Tester*

6.1.1 ± 5% accuracy of full scale

6.1.2 Die contact tool can be in contact with die edge from end-to-end.

6.2 *Hot Plate* — optional

6.3 *Microscope* — optional

7 Material

7.1 *Silicon Die* — 2 mm × 2 mm × 0.3 to 0.5 mm

7.2 *Leadframe*

7.3 *Die Attach Paste*

8 Test Specimen

8.1 Dispense die attach paste by dispensing, stamping, or screen printing.

8.2 Bond die and leadframe pad.

8.3 Cure the paste per recommendation and allow to cool to ambient.

NOTE 1: Height of fillet shall be less than half of the thickness of the die.

NOTE 2: Thickness of die attach paste shall be within the range of 5 to 30 μ m before or after cure.

NOTE 3: Assembled parts shall not be exposed to a curing temperature higher than the peak recommended temperature for more than 30 seconds.

9 Sampling Plan

9.1 Number of specimens tested shall be 5 or more.

1 Available through the Naval Publications and Forms Center, 5801 Tabor Avenue, Philadelphia, PA 19120-5099, USA. Telephone: 215.697.3321

10 Procedure

10.1 Set a test specimen on the die shear tester.

10.2 Confirm that the die contact tool contacts the die side in half of the area or more and that the die contact tool does not touch the fillet.

10.3 Shear the specimen with the tester.

10.4 Record the strength.

10.5 Observe failed parts and classify in the following modes:

Mode 1: Die breakage

Mode 2: Adhesive failure between die and die attach paste

Mode 3: Cohesive failure

Mode 4: Adhesive failure between die attach paste and substrate

Mode 5: Substrate deformation

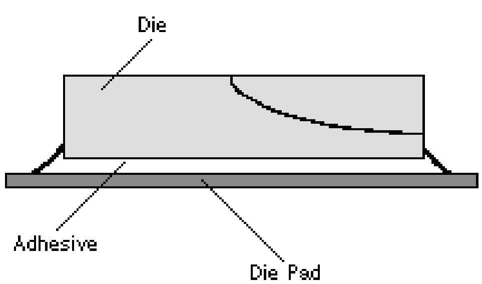

Figure 1
Mode 1 — Break-In Die

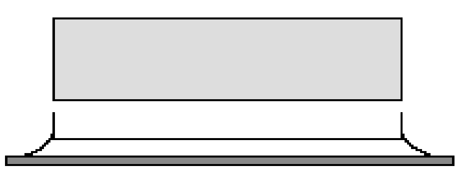

Figure 2
Mode 2 — Interface Failure: Die-to-Adhesives

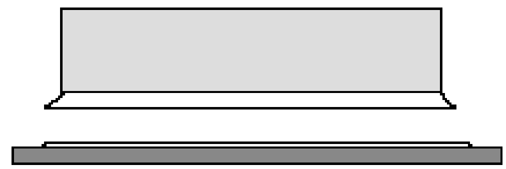

Figure 3
Mode 3 — Break-In Adhesives

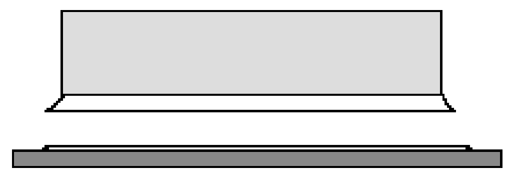

Figure 4
Mode 4 — Interface Failure:Adhesives-to-Die Pad

NOTE 4: In the case of hot die shear strength testing, the hot temperature shall be agreed between user and supplier.

Procedure is as follows:

1. Set and raise the hot plate temperature
2. Confirm that actual temperature is within the range of ± 10° C at the set temperature.
3. Put a specimen on the hot plate and follow Section 10.3 after 10 to 20 seconds.

11 Calculation of Result

11.1 Average strength and standard deviation shall be calculated if required.

12 Report

12.1 The following information shall be reported in the attached form:

12.1.1 Type of die attach paste

12.1.2 Type of leadframe and leadframe plating

12.1.3 Thickness of die and surface condition (attached side) of the die.

12.1.4 Cure schedule and atmosphere (air or nitrogen)

12.1.5 Information about die attach paste thickness, dispense weight, or bond line thickness before and after cure.

12.1.6 Die shear speed

12.1.7 Die shear strength in N (kgf)/die unit (complete data or an average)

12.1.7.1 Standard deviation when number of specimens tested is adequate.

12.1.8 Temperature in hot die shear testing.

APPENDIX 1

NOTE: The material in this appendix is an official part of SEMI G63 and was approved by full letter ballot procedures in 1995.

A1-1 Purpose

The purpose of this appendix is to indicate that speed and height of the die contact tool affect die shear strength results.

A1-2 Test Results

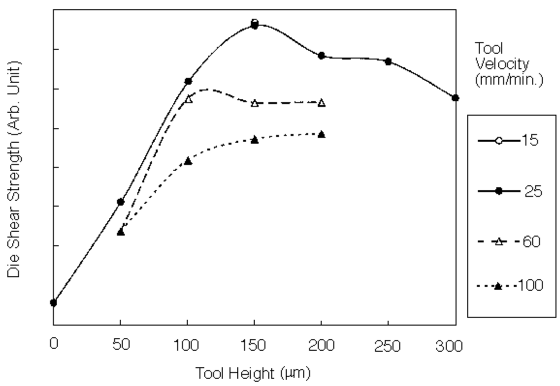

Figure A1-1
Tool Velocity Test Results

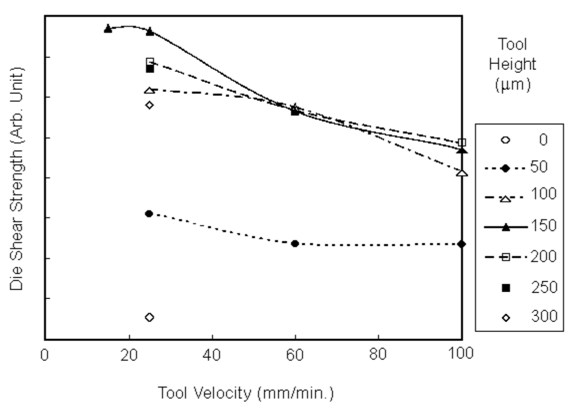

Figure A1-2
Tool Height Test Results

A1-2.1 *Summary*

A1-2.1.1 *Shear Speed*

a. Some adhesive might yield variable results due to the relationship of the shear speed and failure speed.

b. Some equipment with high shear speed could yield low strength due to poor sensitivity at the peak of the load.

A1-2.1.2 *Height of the Die Contact Tool*

a. In case of low height, fillet level might affect the strength.

b. In case of high height, a variable result might be obtained since the tool pulls the die and it tears the adhesive.

SEMI G64-96
SPECIFICATION FOR FULL-PLATED INTEGRATED CIRCUIT LEADFRAMES (Au, Ag, Cu, Ni, Pd/Ni, Pd)

1 Purpose

1.1 This specification is intended as a guideline for evaluating plating layer characteristics required by users of full-plated leadframes for plastic semiconductor packages.

1.2 *Background* — Full-plated leadframes have received attention in recent years as a possible solution to challenges and restrictions resulting from the effects of Pb on the environment, package reliability improvement due to the P.P.F. process, lead coplanarity on fine-pitched leadframes, and lead bridges with solder plating.

2 Scope

2.1 The specification and test procedures detailed in this document apply to full-plated leadframes.

2.2 *Units* — SI units are used in this document.

3 Referenced Documents

3.1 *Priority* — To avoid confusion, the order of precedence when ordering leadframes shall be as follows:

1. Purchase Order (agreed between user and supplier)
2. This Specification
3. Referenced Documents

3.2 *SEMI Standards*

ISO-9227 — Corrosion Tests in Artifical Atmospheres - Salt Spray Tests

4 Terminology

4.1 *finish plating* — Final plating layer whose electrodeposits fulfill the main purpose of the required characteristic.

4.2 *solderability* — An index of the wettability and coverage with solder of lead surface.

4.3 *underplating* — Plating layers that complete the required characteristics of the final plating layer and lies between the base material and final plating layer.

5 Materials

5.1 *Base Material* — Cu alloys or Fe/Ni alloys.

5.2 *Plating Material* — Underplating and Finish plating are shown in Table 1.

1 Military Standards,Naval Publications and Form Center,5801 Tabor Ave., Philadelphia, PA19120

2 Japanese Standards Association, Akasaka, Minato-ku, Tokyo

3 ANSI, 1430 Broadway, New York, NY 10018

Table 1 Underplating and Finish Plating

		Base Material	
Finish Plating	*Underplating*	*Cu-Alloys*	*Fe, Ni-Alloys*
Au (MIL-G-45204)	-	N/A	X
	Ni	X	X
Ag (QQS-365)	-	X	N/A
	Cu	X	X
Cu (MIL-C-14550)	-	X	X
	Ni	X	X
Ni (QQN-290)	-	X	X
	Cu	X	X
Pd/Ni-Alloy	-	X	X
	Ni	X	X
	Cu	X	X
Pd	-	X	X
	Ni	X	X
	Cu	X	X
	Pd/Ni-Alloy	X	X

6 Plating Specification

6.1 *Plating Thickness* — For full-plated leadframes, the designed thickness including under plating is restricted as follows to limit the effects of thickness variation on coplanarity and outer lead width.

Designed thickness including under plating-1 / Ag-plating: 5 µm MAX

Designed thickness including under plating-2 / Au, Cu, Ni, Pd/Ni-Alloy, Pd plating: 2 µm MAX

6.2 *Visual Inspection* — Rejectable conditions are as follows:

1. Any bare spots, or missing plating in critical area as defined the coined areas or minimum flat wire bond area in the appropriate leadframe specification.
2. Any peeling or blistered plating.
3. Any nodules in critical area as defined the coined areas or minimum flat wire bond area in the appropriate leadframe specification.

   NOTE: Nodules not exceeding 0.0381 mm in a surface dimension and 0.0127 mm in height, in non-critical areas are allowed providing there are no more than one per internal lead finger or six (6) per leadframe.

4. Any pits which exceed 0.008 mm in depth or 0.0127 mm in a surface dimension in critical areas or 0.0254 mm in depth or 0.051 mm in a surface dimension in non-critical areas.
5. Any scratches or scrapes in the metallization plating which expose underplating or base material.
6. Any scratches or scrapes in critical area which cause a build up of material in excess of 0.0127 mm in height.
7. Any foreign material, contamination, or tarnish.
8. Non-uniformity or rough-plated surface.

6.3 *Visual Inspection after Baking* — The test procedure is described in Section 9.3. Visual inspection after baking shall be performed according to the procedure in Section 9.2.1.

6.4 *Corrosion Resistance (not applicable to Cu plating)* — In the test result, allowable corrosion specification shall be agreed upon between user and supplier.

6.5 *Surface Ion Contamination* — Allowable ion species and ion concentration shall be agreed upon between user and supplier.

6.6 *Adhesion* — If there is any plating film on the test tape, the component shall be rejected. Adhesive test should be performed according to the procedure in Section 9.6.

6.7 *Functional Tests*

6.7.1 *Die Attach* — Agreed upon between user and supplier.

6.7.2 *Wire Bond* — Agreed upon between user and supplier.

6.7.3 *Solderability* — The criteria for acceptable solderability are as follows:

1. The dipped portion of the samples is at least 95% covered by a continuous solder coating.
2. Pinholes, voids, porosity, non-wetting, or dewetting do not exceed 5% of total area.

NOTE: Solderability criteria for Ni and Cu plating are established by the user and supplier and are excluded here.

7 Equipment

7.1 Fluorescent X-ray spectremeter

7.2 Binocular-microscope, 10~30x magnification

7.3 Neutral salt spray test equipment

7.4 Ion chromatography (Anion, Cation)

7.5 Hot plate or Heater block

7.6 Solder pot

7.7 Meniscograph

8 Sampling

Sampling plan shall be agreed upon between user and supplier.

9 Test Methods

9.1 *Thickness* — Plating thickness shall be measured by fluorescent X-ray spectrometer.

9.2 *Visual Inspection*

9.2.1 *Magnification* — Unless otherwise specified, visually inspect the plating surface under a microscope at 10× magnification. 30× magnification shall be used for confirmation.

9.3 *Baking Test*

9.3.1 *Baking Conditions* — Samples are heated in air on hot plates or heater block.

9.3.2

Table 2

Finish Plating/Base Material	*Cu-Alloys*	*Fe/Ni-Alloys*
Au*	450°C × 3 min.	450°C × 3 min.
Ag	300°C × 3 min.	400°C × 3 min.
Cu**	200°C × 1 hour	200°C × 1 hour
Ni**	400°C × 3 min.	400°C × 3 min.
Ni/Pd Alloy	200°C × 1 min.	200°C × 1 min.
Pd	300°C × 1 min.	300°C × 1 min.

* May be changed by agreement between user and supplier to 400°C x 1 min or 450°C x 2 min or less, to account for changes in plating thickness, base material, or other plating parameters.

** Surface oxidation and discoloration detected by visual inspection are acceptable. Furthermore, parameter of solderbility evaluation for flux, dipping method, etc. are to be determined by agreement between user and supplier.

9.3.3 Visual inspection after baking shall be performed according to the procedure in Section 9.2.1.

9.4 *Corrosion Test* — Atomize the test sample in a test container using a 5% neutral sodium chloride solution of 8.8~7.2pH at 35 ± 1°C for 24 hours. This test follows ISO-9227.

9.5 *Surface Ion Contamination* — The measurement follows SEMI G52.

9.6 *Adhesion Test* — Place the strip of tape (SCOTCH[a] #540, #610, #810, or equivalent) across the plated area. Press firmly with fingertips or other smooth object. Peel the tape quickly off the plated surface. The plating surface may be scored before the tape test in accordance with the joint agreement between user and supplier.

9.7 *Functional Tests*

9.7.1 *Die Attach* — Agreed upon between user and supplier.

9.7.2 *Wire Bond* — Agreed upon between user and supplier.

9.7.3 *Solderability* — The procedure for accelated aging test shall be agreed upon between user and supplier (see Appendix 1).

APPENDIX 1
SOLDERABILITY TEST

NOTE: This appendix was approved as an official part of SEMI G64 by full letter ballot procedure.

A1-1 Accelerated Environment Simulation

Determination, due to the environment, may be simulated by exposure to a hot plate that reproduces the heat characteristics of assembly (a), and by steam aging to simulate the storage environment. The following are methods for accelerated environment simulations (b):

a. Place samples in air on a hot plate or a heat block. Temperature and duration are detailed in 9.3, and represent the heat characteristics of assembly.

b. Steam aging test is based on MIL-STD-883D, Method 2003.7, and simulates environmental conditions.

A1-2 Soldering Parameter

Baked test specimens shall be dipped into flux conforming to MIL-P-14256, type-R, for 5 to 10 seconds, and then dipped in a solder bath conforming to QQ-S-571 for 10 ± 1 seconds at a solder pot temperature of 230 ± 5°C.

A1-3 Evaluation of Solderability

A1-3.1 *Wetting Area* — After cleaning solder dipped specimen with alcohol to remove flux, visually inspect under a microscope at 10x magnification. Solder must cover 95% or more of surface area, based on MIL-STD-883D, Method 2003.7.

A1-3.2 *Wetting Time (zero-cross-time)* — Solder that conforms to conditions below is evaluated according to JIS-C-0053, or may be evaluated by a method determined by user and supplier for certain leadframe shapes.

1. Temperature: 230 ± 5°C
2. Dipping speed: 2 mm/second
3. Dipping depth: 2 mm
4. Flux: Rosin flux (MIL-F-14256, type-R)
5. Solder composition: 63 Sn / 37 Pb (QQ-S-571)

SEMI G65-96
TEST METHOD FOR EVALUATION OF LEADFRAME MATERIALS USED FOR L-LEADED (GULL WING TYPE) PACKAGES

1 Purpose

1.1 This test method describes an evaluation method for bending characteristics of leadframe materials used for L-leaded packages.

NOTE 1: The lead fatigue test described in MIL-STD-883/2004 is not suitable for evaluating the bending characteristics of fine pitch leadframes or leadframes used for L-leaded packages because the method is based on reforming the leads.

2 Scope

2.1 This test method may be applied to leadframes for L-leaded packages such as QFP, SOP, TSOP, etc.

2.2 This test method may also be applied to any leadframe materials with thickness ≤ 0.15 mm.

2.3 The test method may be used in trim and form tool suppliers, leadframe material suppliers, leadframe manufacturers, and package engineers.

3 Referenced Documents

3.1 *Military Standard*[1]

MIL-STD-983 — Method 2004, Lead Integrity

4 Terminology

4.1 *crack (of leadframe)* — Micro cleavage or fracture on surface of outside of lead which is caused by bending (see Figure 1).

4.2

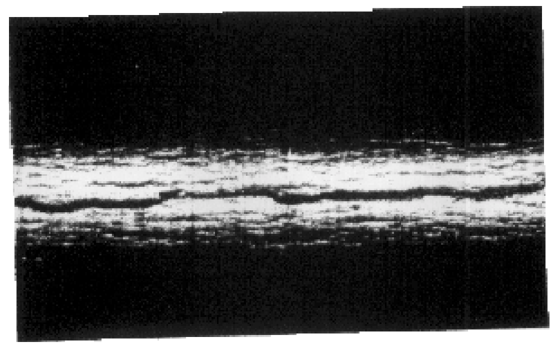

Figure 1
Crack

4.3 *orange peel (of leadframe)* — Micro roughness on surface of outside of lead caused by bending (see Figure 2).

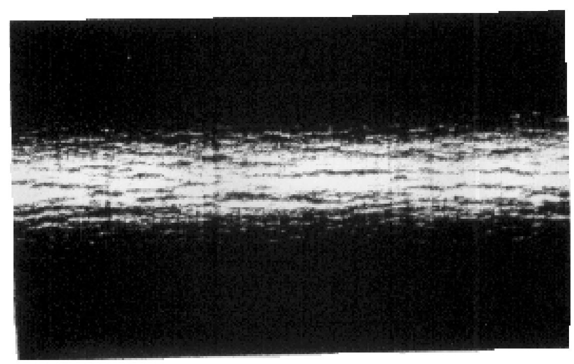

Figure 2
Orange Peel

4.4 *spring back* — Difference between designed angle of forming tool and actual lead form angle.

NOTE 2: In this method, the angle of forming tool is 90°. The value is defined by:

Actual lead bend angle 90°.

1 Military Standards, Naval Publications and Form Center, 5801 Tabor Ave., Philadelphia, PA 19120

5 Summary of Method

The leadframe samples (etched using a standard mask agreed between user and supplier) will be formed using a "W" forming tool. The resulting form angle is to be measured and surface characteristics such as cracking and orange peel are to be visible for compliance to the agreed upon specification.

6 Interference

If the forming tool does not meet the specification, lead movement during forming may result in poor repeatability.

7 Significance

7.1 Devices manufactured with leadframes of different spring back characteristics, may cause board assembly problems due to lead positional differences.

7.2 Crack in the leadframe may cause poor contact reliability with board.

8 Equipment

8.1 *Tensile Tester* — With minimum 9800N force and 1% accuracy.

8.2 *"W" Forming Tool* — With R = 0, 0.1 and 0.2 and form angle of 90°. The dimension and configuration are shown in Figures 3—7

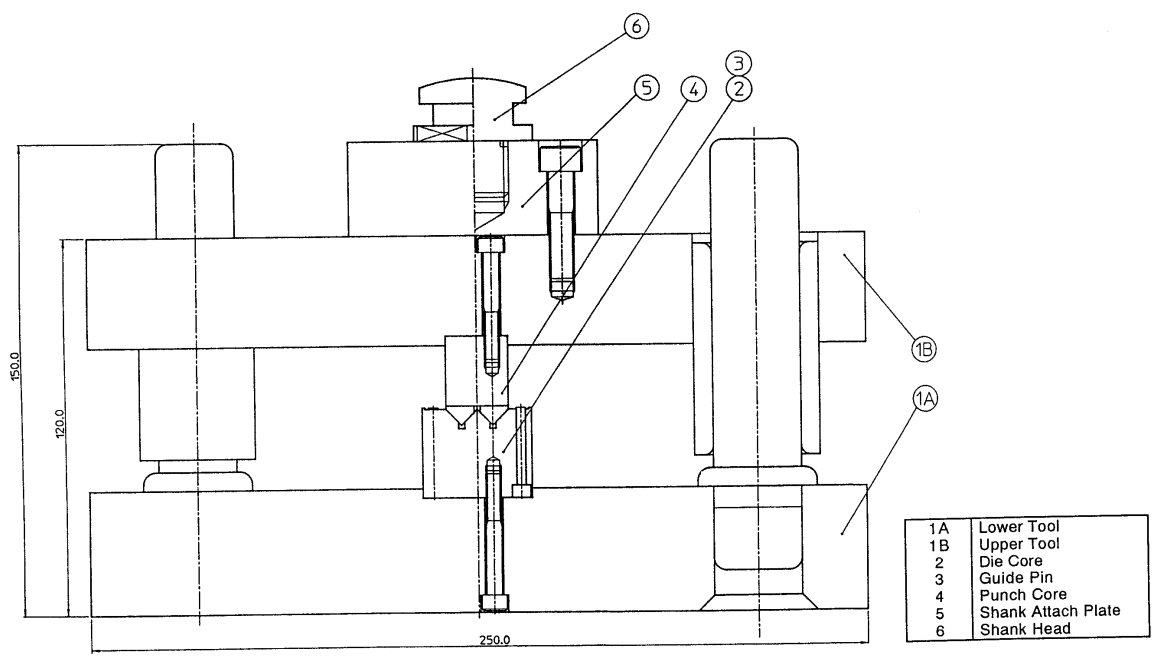

Figure 3
W-Bending Test Tool

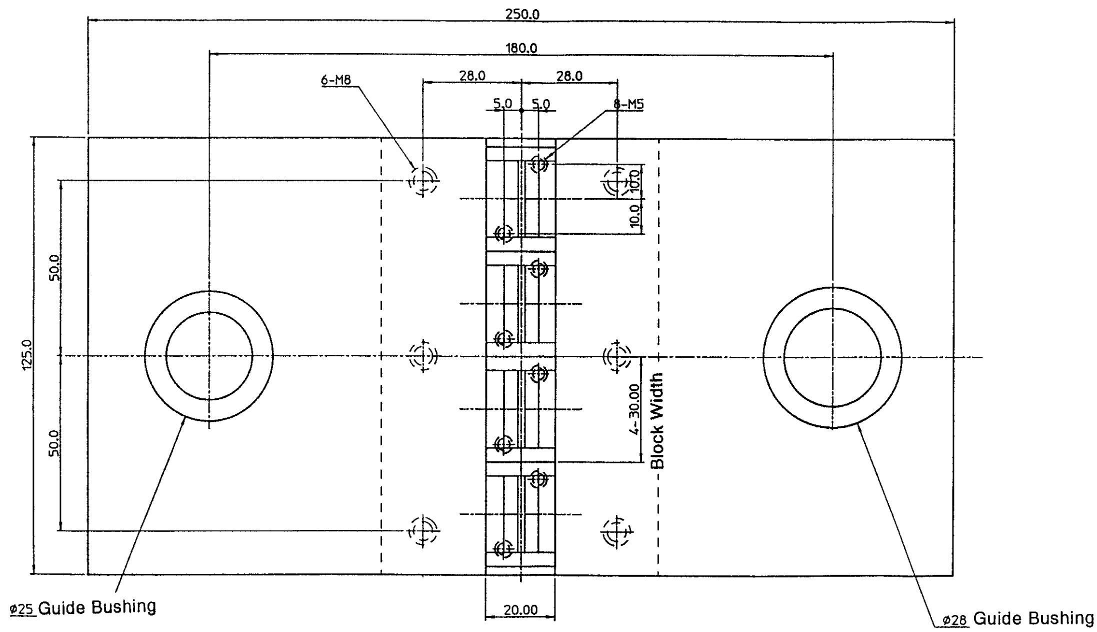

Figure 4
Upper Tool Detail

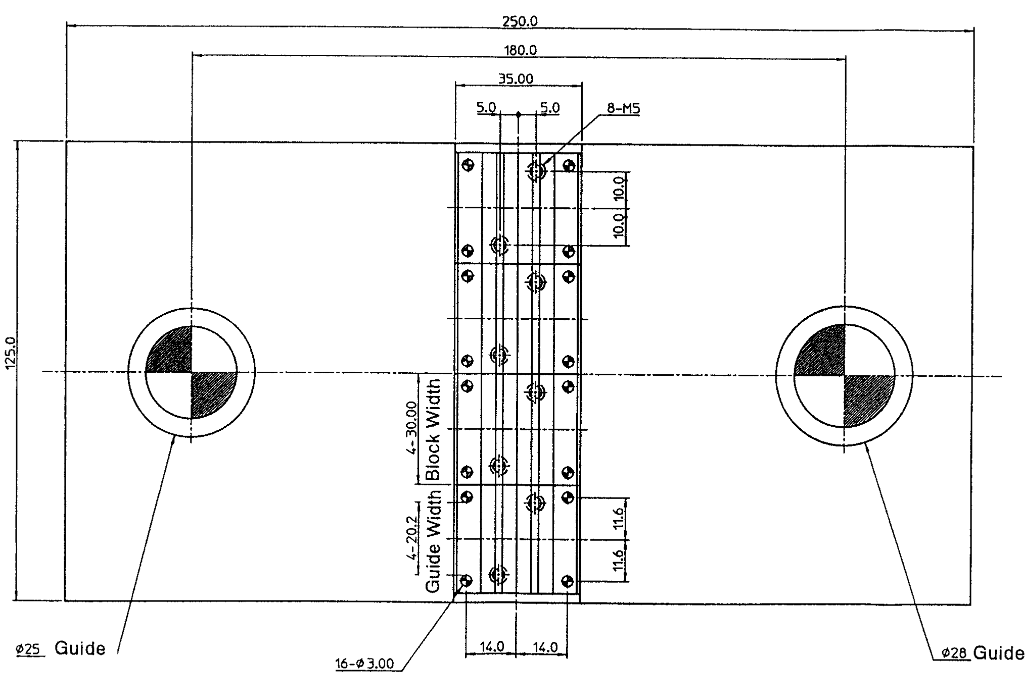

Figure 5
Lower Tool Detail

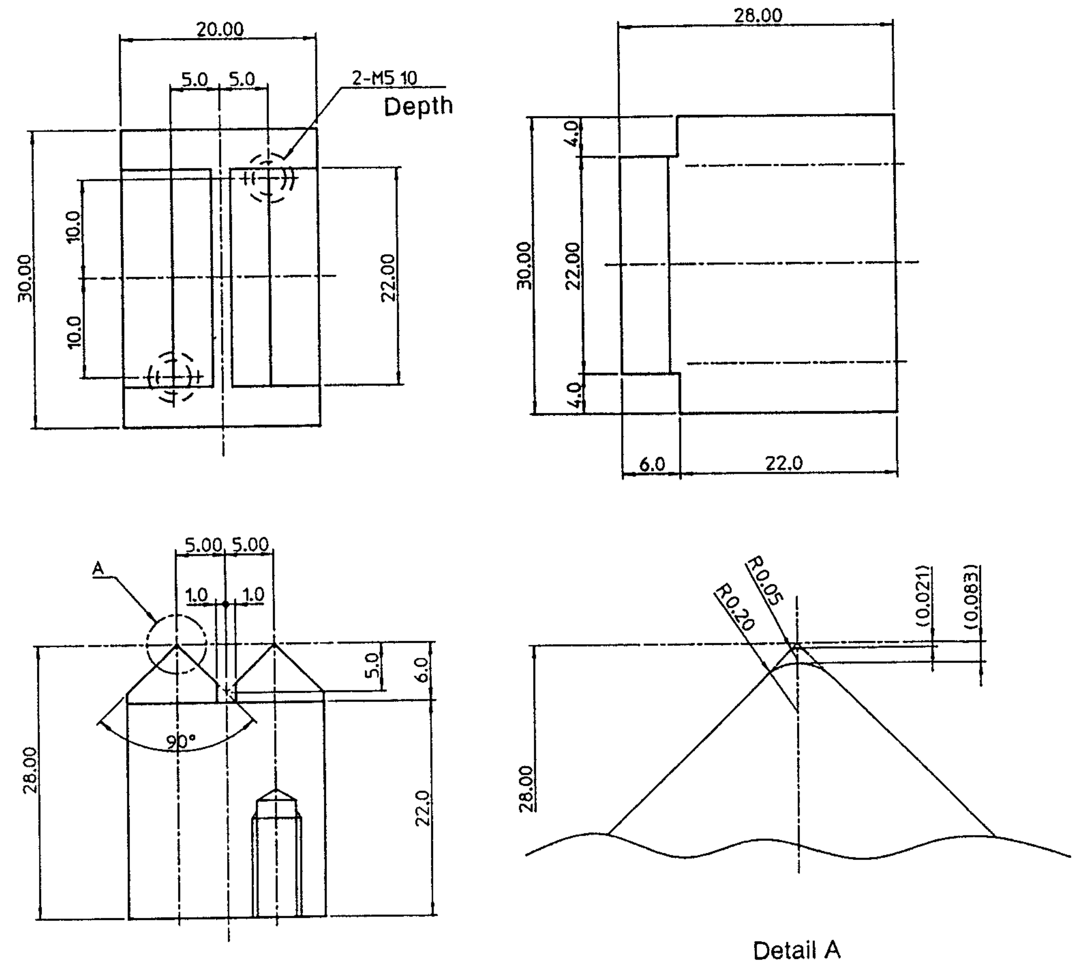

Figure 6
Punch Core Detail

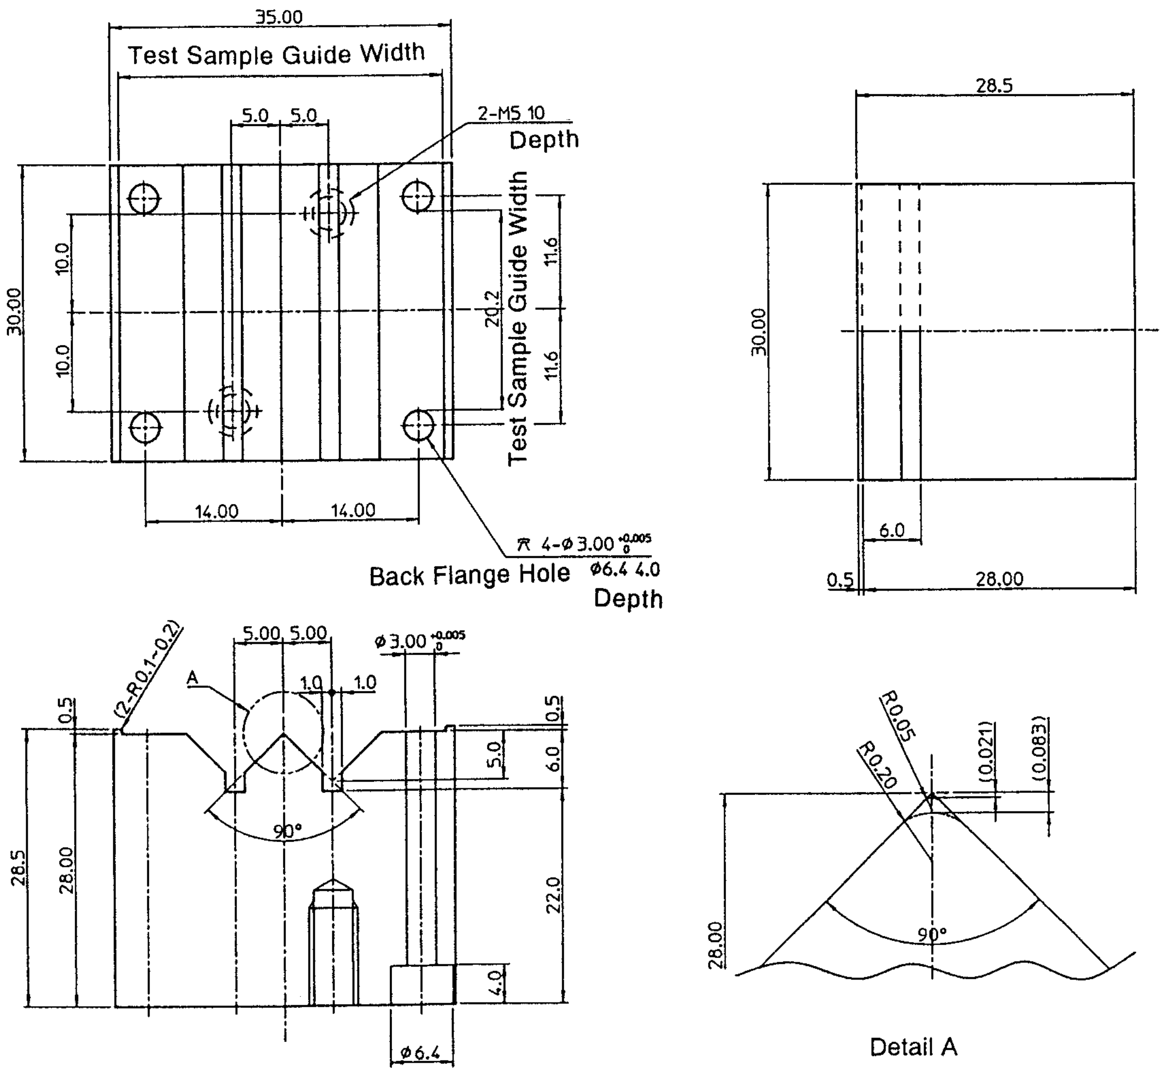

Figure 7
Die Core Detail

8.3 *Micrometer*

8.4 *Microscope* — 75× used to inspect lead surface characteristics.

8.5 *Protractor* — 10× and accuracy 0.1° used to measure the leadform spring back.

8.6 *Projector* — 10×.

9 Sampling Plan

9.1 The sampling plan shall be agreed between user and supplier. It is suggested that a minimum of five (5) samples (2 leads per sample) of 0.3 mm width on 0.65 mm pitch, be used for these tests.

NOTE 3: If the leadframe is four-sided, take samples from both orthogonal directions.

10 Sample Preparation

10.1 The samples are prepared by etching a leadframe pattern into a blank piece of the leadframe material using a standard mask. An example of the recommended configuration is shown in Figure 8.

	A	B	C	D	E	F	F′	G	H
LEAD PICTH	—	—	1.00	0.80	0.65	0.50	0.50	0.40	0.30
LEAD WIDTH	10.0	5.00	0.40	0.35	0.30	0.20	0.20	0.16	0.12
LEAD COUNTE	1	1	12	14	16	25	25	31	42

Note : Tolerance ±0.030 mm

Figure 8
Standard Sample Configuration

NOTE 4: SEMI/Japan has copies of this artwork for use by companies.

10.2 Measure the sample thickness at three (3) points on the siderail using micrometer.

11 Setup and Procedure

11.1 *Setup*

11.1.1 Warm up and calibrate the tensile tester according to the operation manual.

11.1.2 Set the “W” forming tool in the tensile tester.

11.1.3 Set the tensile tester in the push mode and adjust the force to 9800N.

11.2 *Procedure*

11.2.1 Place the sample on the lower section of the “W” forming tool.

11.2.2 Lower the upper section of the “W” forming tool at the speed of 1 to 5 mm/min.

11.2.3 Raise up the upper section of the “W” forming tool and remove the sample carefully.

11.2.4 Repeat the test for the other samples.

11.3 *Measurement*

11.3.1 Remove the leads from the bent sample by cutting at the cutting position.

NOTE 5: Perform this operation carefully to avoid reforming the leads.

11.3.2 Select two (2) leads from one sample.

11.3.3 Observe the outside surface of the lead and take a photograph with a microscope set at 75× magnification.

11.3.4 Set the lead sample in a projector.

11.3.5 Project the picture of the sample on the screen.

11.3.6 Adjust the protractor to the picture and read the form angle.

12 Calculation

12.1 Calculate the spring back value as follows:

Spring back = actual angle of sample - designed form angle

12.2 Calculate the average spring back value.

12.3 Round the result to one significant figure.

13 Report

The report shall contain the following information:

13.1 Leadframe material name, lot number, and vendor

13.2 Average thickness (per 10.2)

13.3 Photograph taken using 75× magnification (per 11.3.3)

13.4 List of observations (per 11.3.3)

NOTE 6: Classify observation results as crack, orange peel, and good according to their definition in Section 4. If required, further classification should be agreed between customer and vendor.

13.5 Spring Back Value (per 11.3.4 to 11.3.6) — Average, minimum, maximum

13.6 Rejection — The limit shall be agreed between user and supplier.

SEMI G66-96

TEST METHOD FOR THE MEASUREMENT OF WATER ABSORPTION CHARACTERISTICS FOR SEMICONDUCTOR PLASTIC MOLDING COMPOUNDS

1 Purpose

1.1 This method describes a procedure for measuring the water absorption rate for plastic molding compounds and provides a method to calculate the diffusion and solubility coefficients, which are required to simulate the water absorption characteristics.

2 Scope

2.1 This method may be applied to all semiconductor plastic molding compounds.

2.2 This method may be used to characterize molding compounds in development.

2.3 Packaging engineers may simulate the water absorption characteristics and their significance in relation to package cracks at soldering by using calculated diffusion and solubility coefficients.

3 Referenced Documents

None.

4 Terminology

4.1 *diffusion coefficient, D* — The diffusion rate of water into a molding compound (see Appendix 1 and Figure 1).

4.2 *solubility coefficients, S* — Ratio of saturated moisture concentration in molding compounds to partial pressure of moisture in environment (see Appendix 1 and Figure 1).

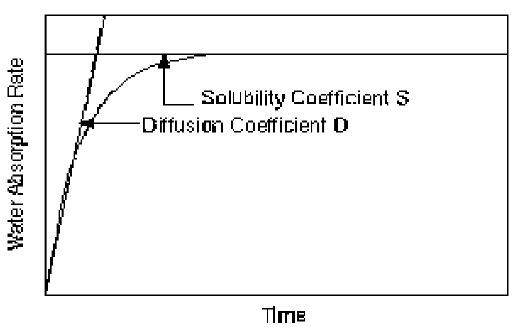

Figure 1
Concept of Diffusion and Solubility Coefficients

5 Summary of Method

5.1 This method is based on the measurement of the increase in weight, due to water absorption, after exposing the molding compound to a high-temperature, high-humidity environment.

6 Equipment

6.1 *Balance* — An analytical balance capable of reading 0.0001g.

6.2 *High-Temperature Chamber* — Capable of maintaining a uniform temperature of 125 ± 3°C.

6.3 *Temperature/Humidity Chamber* — Capable of maintaining a uniform temperature of 85 ± 2°C and 85 ± 5% relative humidity.

6.4 *Desiccator (1)* — To hold specimens during cool-down from high-temperature conditioning.

6.5 *Desiccator (2)* — This desiccator, with water in the bottom rather than drying compound, is to hold the specimens after exposure to heat and humidity.

6.6 Mold for specimen preparation.

7 Reagents and Materials

7.1 *Deionized Water* — Resistivity ≥15M ohm-cm at 25°C

8 Sampling Plan

8.1 At least three samples shall be chosen for each molding type for each test.

9 Test Specimens

9.1 Test specimens are required as follows:

9.1.1 Specimens for diffusion area.

Diameter — 50 ± 1 mm

Thickness — 3 ± 0.2 mm

9.1.2 Specimens for saturated area.

Diameter — 50 ± 1 mm

Thickness — 1 ± 0.2 mm

10 Equipment Set-Up

10.1 Refer to manufacturer's operation manuals.

11 Procedure

11.1 *Specimen Preparation*

11.1.1 Prepare the specimens by molding samples using the specimen mold and conditions recommended by the molding compound manufacturer.

11.1.2 Post-mold cure the specimens to recommended conditions using the high-temperature chamber.

11.2 *Specimen Conditioning*

11.2.1 Dry the specimens at 125°C in the high-temperature chamber for 24 hours minimum.

NOTE 1: If the samples are already dry (e.g., samples directly from post-mold cure), additional conditioning is not required.

11.2.2 Place the specimens in the desiccator (1) and allow to cool to room temperature.

11.2.3 Weigh the specimens to the nearest 0.0001g.

11.3 *Water Absorption Exposure and Reconditioning*

11.3.1 *Diffusion Area*

11.3.1.1 Place the conditioned specimens (3 mm thickness) in the high-temperature/humidity chamber set at 85°C and 85% relative humidity for 24 ± 1 hours.

NOTE 2: The specimens should be placed to avoid any contact with each other and with the walls of the chamber, e.g. to use a holder or to place on a wire net.

11.3.1.2 Remove the specimens from the chamber and wipe off any excess water from the surfaces with a clean cloth or absorbant paper.

11.3.1.3 Place the specimens in desiccator (2) and allow to cool to room temperature.

NOTE 3: The specimens should be placed to avoid any contact with each other and with the walls of the chamber (e.g., to use a holder or to place on a wire net).

11.3.1.4 Re-weigh the specimens to the nearest 0.0001 g.

11.3.2 *Saturated Area*

11.3.2.1 Place the conditioned specimens (1 mm thickness) in the high-temperature/humidity chamber set at 85°C and 85% relative humidity for 168 ± 4 hours.

NOTE 4: The specimens should be placed to avoid any contact with each other and with the walls of the chamber (e.g., to use a holder or to place on a wire net).

11.3.2.2 Remove the specimens from the chamber and wipe off any excess water from the surfaces with a clean cloth or absorbant paper.

11.3.2.3 Place the specimens in desiccator (2) and allow to cool to room temperature.

NOTE 5: The specimens should be placed to avoid any contact with each other and with the walls of the chamber, e.g. to use a holder or to place on a wire net.

11.3.2.4 Re-weigh the specimens to the nearest 0.0001g.

12 Calculations

12.1 *Water Absorption Rate* — The rate is calculated as follows:

$$\text{Water absorption rate (wt\%)} = ((M2 - M1)/M1) \times 100 \quad (1)$$

Where :

M1 is the initial conditioned weight, and

M2 is the reconditioned weight after exposure to temperature/humidity

12.2 *Diffusion and Solubility Coefficients*

12.2.1 There are various methods to calculate diffusion and solubility coefficients. See Appendix 1 for one of these methods.

13 Report

13.1 The following information shall be reported:

1. Manufacturer and identification of molding compound
2. Specimen sizes
3. Test conditions
4. Water absorption rate
5. Date of test

14 Related Documents

14.1 *ASTM Specification*[1]

ASTM D 570 — Standard Test Method for Water Absorption of Plastic

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, PA 19428-2959

APPENDIX 1
APPLICATION NOTES — METHOD OF CALCULATION FOR DIFFUSION AND SOLUBILITY COEFFICIENT

NOTE: This appendix was approved as an official part of SEMI G66 by full letter ballot procedure.

A1-1 Purpose

This application note describes a method for calculating diffusion and solubility coefficients.

A1-2 Solubility Coefficient, S

The solubility coefficient is given from the data of saturated area as follows:

$$S = M_s \times d / P \times 1000 \qquad (2)$$

Where :

S = Solubility coefficient ($(mg/cm^3) / (kg/mm^2)$)

M_s = Saturated moisture absorption rate (wt%) (data from saturated area test)

d = Density of specimen (g/cm^3)

P = Partial pressure of moisture in environment (Pa) (value at 85°C in this test)

A1-3 Diffusion Coefficient, D

The moisture absorption rate in resin exposed for relatively short term is calculated using the following equation based on Fick's formula:

$$M_t / M_s = 4 \times \{ (D \times t) / (l^2 \times \pi) \}^{1/2} \qquad (3)$$

Then :

$$D = l^2 \times M_t^2 \times \pi / (t \times 4^2 \times M_s^2) \qquad (4)$$

Where :

D = Diffusion coefficient (cm^2 / h)

t = Time of moisture absorption (h) (data from diffusion area test - 24 hours)

M_t = Moisture absorption rate at the time "t". (wt%) (data from diffusion area test)

l = Thickness of the specimen (cm) (data from diffusion area test = 0.3 cm)

M_s = Saturated moisture absorption rate (wt%) (data of saturated area test)

SEMI G67-0996
TEST METHOD FOR THE MEASUREMENT OF PARTICLE GENERATION FROM SHEET MATERIALS

1 Purpose

This test method describes a procedure to measure particles on sheet materials.

2 Scope

The method described may be used for the measurement of particles on items such as:

Leadframe Interleaves

Cleanroom Paper

Packing Material

The procedures may be used by the material manufacturer for quality control or by a customer at incoming inspection.

3 Referenced Documents

None.

4 Terminology

None.

5 Summary of Method

The method is based on measuring a background particle count in a clean enclosure and then measuring the increased particle count when items under test are submitted to handling operations likely to generate particles.

6 Interference

6.1 Care must be taken to avoid contaminating the clean bench when sheet materials are placed inside. All external packaging material shall be removed and the internal packaging shall be cleaned by appropriate means prior to placing inside the bench.

6.2 A method of cutting the specimens to size, if performed, must not add to, or detract from, the contamination levels on the sheet materials.

6.3 Care must be taken to avoid contaminating the specimens from the human body and clothes when the sheet materials are prepared for the test method.

7 Equipment

7.1 *Particle Counter and Recorder*

7.2 *Clean Bench with Full Gloves and a Dust Particle Measurement Port* — See Figure 1.

7.2.1 Air flow speed in the clean bench should be 0.6 m/sec.

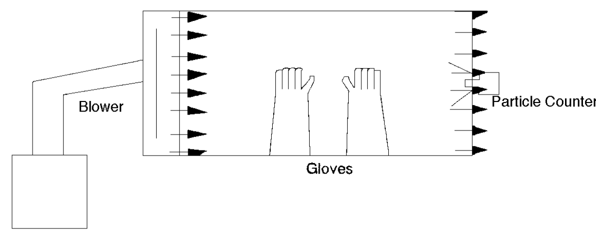

Figure 1
Clean Bench Configuration

8 Sampling

Sampling plans shall be agreed between user and supplier.

9 Test Specimen

Specimen size shall be agreed between user and supplier. It is recommended that a 152.4 mm × 203.2 mm (6 × 8 inches) test piece be used.

10 Equipment Set-Up

10.1 The particle counter shall be set up with the probe in the clean bench. Calibrate the counter in accordance with the equipment manufacturer's instructions.

10.2 Allow the clean bench to come to equilibrium and perform a background particle count.

NOTE 1: Between each test, allow the clean bench to return to a stable background particle count before proceeding with the next test.

NOTE 2: After several thousand particles have been measured, the clean bench must be cleaned before making the next measurement.

11 Test Procedure

11.1 Place the items to be tested in the clean bench and allow the clean bench to return to a stable background level for particle count.

11.2 *Crumpling Test*

11.2.1 Crumple a test specimen in gloved hands at the rate of one (1) crumple every fifteen (15) seconds and record the maximum particle count.

11.2.2 Record the maximum particle count and the initial background count.

11.3 *Friction Test*

11.3.1 Place two sheets of the material to be tested face to face and rub together three (3) times in ten (10) seconds.

11.3.2 Record the maximum particle count and the initial background count.

11.4 *Tearing and Crumpling Test*

11.4.1 Tear a sheet into five (5) pieces at the rate of one (1) tear every five (5) seconds. Crumple the pieces in gloved hands at the rate of one (1) crumple every fifteen (15) seconds.

11.4.2 Record the maximum particle count and the initial background count.

12 Calculations and Reporting Results

12.1 For each measurement and test method type, calculate the particle count on the material under test as follows:

Particle Count (no./m^3) = (Measured Count from each test) - (Background Count)

12.2 Average the results for each test type.

13 Report

The test report shall include the following items:

Material Designation under Test

Manufacturer

Shipping Lot Number

Test Date

Test Conditions — temperature, humidity in the clean bench

Particle Counter Sensitivity

Test Time

Results for Each Test Type in particles/m^3

NOTE 3: If the test is performed by the manufacturer, some of these items may be replaced by in-house requirements such as manufacturer lot number.

SEMI G68-0996
TEST METHOD FOR JUNCTION-TO-CASE THERMAL RESISTANCE MEASUREMENTS IN AIR ENVIRONMENT FOR SEMICONDUCTOR PACKAGES

1 Purpose

The purpose of this test is to determine the thermal resistance of semiconductor packages using thermal test chips. This test method deals with junction-to-case measurements of thermal resistance in air environment.

2 Scope

2.1 The results of this test method are used to obtain the junction temperature.

2.2 The measurement results are usually different from the results obtained by testing in the fluid bath environment described in SEMI G30 and SEMI G43.

2.3 This test method uses SI units.

3 Limitation

This method applies only to packages whose surface is wide enough to place a thermocouple.

4 Referenced Documents

4.1 *SEMI Specifications*

SEMI G30 — Test Method for Junction-to-Case Thermal Resistance Measurements of Ceramic Packages

SEMI G32 — Guideline for Unencapsulated Thermal Test Chips

SEMI G38 — Test Method for Still- and Forced Junction-to-Ambient Thermal Resistance Measurements of Integrated Circuit Packages

SEMI G42 — Specification for Thermal Test Board Standardization for Measuring Junction-to-Ambient Thermal Resistance of Semiconductor Packages

SEMI G43 — Test Method for Junction-to-Case Thermal Resistance Measurements of Molded Plastic Packages

5 Terminology

The following definitions and symbols shall apply to this test:

5.1 *case top temperature measured in air environment, T_t* — In °C, is the temperature at the specified accessible reference point on the package in measured in air environment.

NOTE 1: T_C defined in SEMI G43 is different from T_t.

5.2 *junction temperature, T_j* — In °C, is the temperature of the semiconductor junction on the microcircuit in which the major part of the heat is generated.

5.3 *power dissipation P_H* — In watt, is the heating power applied to the device causing a junction-to reference point temperature difference.

5.4 *thermal resistance measured in air environment, junction to package surface, Ψ_{jt}* — In °C/watt, is the temperature difference from the junction to the center point on the package divided by the power dissipation P_H.

6 Summary of Method

A thermocouple is attached on the surface of the package on the test board.

After the chip is heated, the junction temperature is measured by the diode in the test chip. The surface temperature is measured in an air environment by the thermocouple.

The junction-to-case thermal resistance is calculated using the case temperature, junction temperature and power dissipation.

7 Interference

7.1 It is recommended that an operator who is familiar with the measuring system and test method conduct the actual measurement in order to obtain the best result.

7.2 The procedure for attaching the thermocouple described in Section 12.3 on the test package should be followed in order to obtain the accurate measurement result.

8 Apparatus

8.1 *Thermocouple*

8.1.1 *Material* — Copper-constantan or equivalent

8.1.2 *Temperature Range* — -100 to +300°C

8.1.3 *Wire Size* — No larger than AWG size 36.

8.1.4 *The Junction* — Shall be welded to form a bead rather than soldered or twisted.

8.1.5 *Accuracy* — ± 0.5%

8.2 *Suitable Electrical Equipment* — As required to provide controlled levels of conditioning power and to make the specified measurements.

8.2.1 *Resolution* — 50 µV and 5 µA

8.3 *Wind Tunnel (as necessary)* — See SEMI G38 or equivalent.

9 Materials

9.1 *Test Chip* — Referred to in SEMI G32, or equivalent.

9.2 *Test Board* — Referred to in SEMI G42, or equivalent.

9.3 *Adhesive* — Alpha Cyano-Acrylate

9.4 *Aluminum Foil* — 4 mm × 4 mm.

10 Setup

Warm up the test equipment before measurements.

11 Calibration

Calibrate the equipment in accordance with the operation manual as necessary.

12 Procedure

12.1 *Preparation of Test Package*

12.1.1 Prepare the semiconductor package in which the test chip is mounted.

12.2 Assemble the package on the test board using solder.

12.3 *Attach the Thermocouple*

12.3.1 Apply adhesive on the center point of the package.

12.3.2 Place the thermocouple and aluminum foil on the adhesive and press the aluminum foil using a finger in order to attach the thermocouple on the package surface as close as possible.

12.4 Measure the thermal characteristic of the diode of the test chip.

NOTE 2: It is recommended that the ambient temperature T_a is measured using the thermocouple.

12.5 Mount the test board in a test socket in a still-air enclosure or wind tunnel as necessary.

12.6 *Heating Chip*

12.6.1 Supply power to the chip.

12.6.2 Adjust the measurement equipment to the measured case temperature T_t or the the measured power $P_{H\ (package)}$.

NOTE 3: The thermal resistance usually depends on the power dissipation (see Figure 1). The thermal resistance is variable within a power and stable beyond the power.

12.7 Wait until the thermal characteristic of the diode is stable.

12.8 Calculate the junction temperature T_j by the diode thermal characteristics.

12.9 Measure the case temperature T_t using the thermocouple and record the case temperature.

12.10 Record the voltage and the current in order to obtain the $P_{H\ (package)}$.

13 Calculation

13.1 The thermal resistance of the package can be calculated as follows:

Ψ_{jt} (°C/watt) =

$(T_j — T_t) / P_{H\ (package)}$

14 Report

The following details shall be reported:

a. Description of package

b. Description of test board

c. Power dissipation of test chip

d. Thermal resistance $R_{\Psi jt}$ for test condition

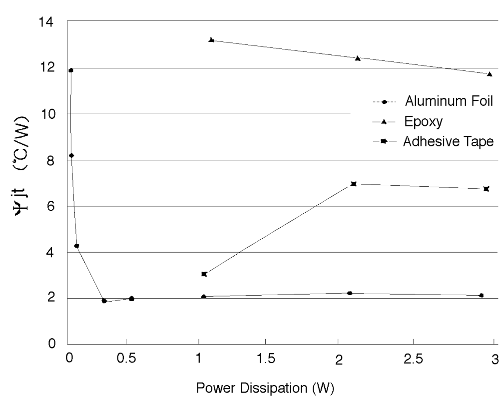

Figure 1
Dependence of $R_{\Psi jt}$ on Power Dissipation

SEMI G69-0996
TEST METHOD FOR MEASUREMENT OF ADHESIVE STRENGTH BETWEEN LEADFRAMES AND MOLDING COMPOUNDS

1 Purpose

1.1 This document describes procedures for measuring adhesive strength between leadframes and molding compounds for semiconductor packages.

1.2 The procedures include shear test, pull test, and three-point bending techniques.

2 Scope

2.1 This document may be used on all types of semiconductor leadframe and molding compound.

2.2 The methods help leadframe manufacturers, molding compound manufacturers and their customers in evaluating leadframes, and molding compounds as a guideline.

2.3 The methods in this document use SI units.

3 Referenced Document

A. Nishimura, I. Hirose and N. Tanaka, "A New Method for Measuring Adhesion Strength of IC Molding Compounds", ASME Journal of Electronic Packaging, Vol. 114, pp 407-412, 1992

4 Terminology

None.

5 Summary of Method

5.1 *Shear Method* — A frustum-shaped button of molding compound on the surface of a leadframe sample is sheared off the leadframe surface using a tensile tester (see Figure 1).

5.2 *Pull Method* — A sample of leadframe material molded into the side of a block of a molding compound is pulled out using a tensile tester (see Figure 2).

5.3 *Three-Point Bending Method* — Molding compound is molded onto the surface of a leadframe sample such that part of the leadframe is free of molding compound adherence to the surface. Using a bending technique, the adherent molding compound is cracked away from the surface. This process is repeated from both sides of the sample in order to calculate the true adhesive strength. (Refer to the paper in Referenced Document and see Figure 3.)

6 Equipment

6.1 *Tensile Tester*

6.1.1 *Measurement Range* — Maximum 980 N (100 kgf)

6.1.2 *Accuracy* — ± 1%

6.1.3 *Crosshead Speed* — 2 – 10 mm/min (recommended), constant speed.

6.1.4 Fixtures suitable for holding the samples, shearing the molding compound, pulling the leadframe, and applying bending load.

6.2 *Chart Recorder*

6.3 Transfer molding machine or suitable replacement that can encapsulate individual samples with required pressure and temperature.

6.4 *Pre-Heater* — High frequency heater for molding compounds.

6.5 *Molds* — Suitable to mold the samples as shown in Figures 1, 2, and 3.

6.6 *Recirculating Air Oven* — With controller in range of 170 – 180 °C.

6.7 Equipment to pre-treat the leadframe sample, as required.

6.8 Ultrasonic inspection apparatus for three-point bending method.

7 Configuration and Dimension of Sample

7.1 The sample configuration and dimensions for measurement are shown in Figures 1, 2, and 3.

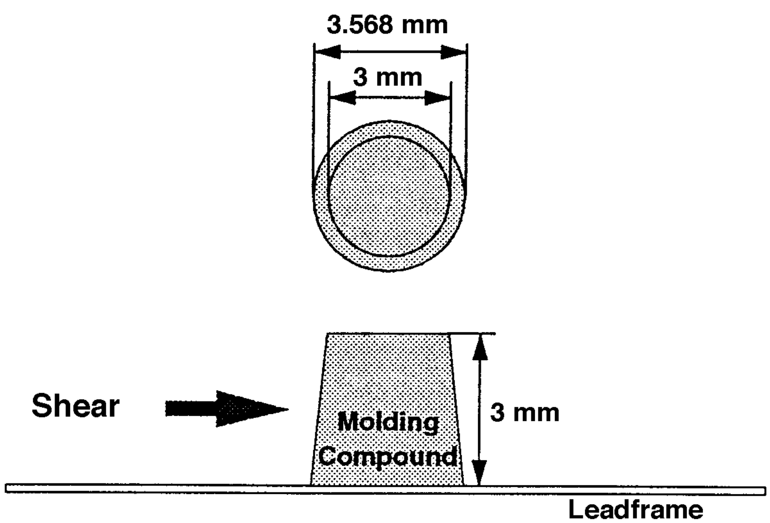

Figure 1
Sample for Shear Method

Adhesive Area	*Leadframe Thickness*	*Height of Molding Compound*
10 ± 0.5 mm^2	0.254–0.125 mm (0.15 mm is recommended)	3 ± 0.15 mm

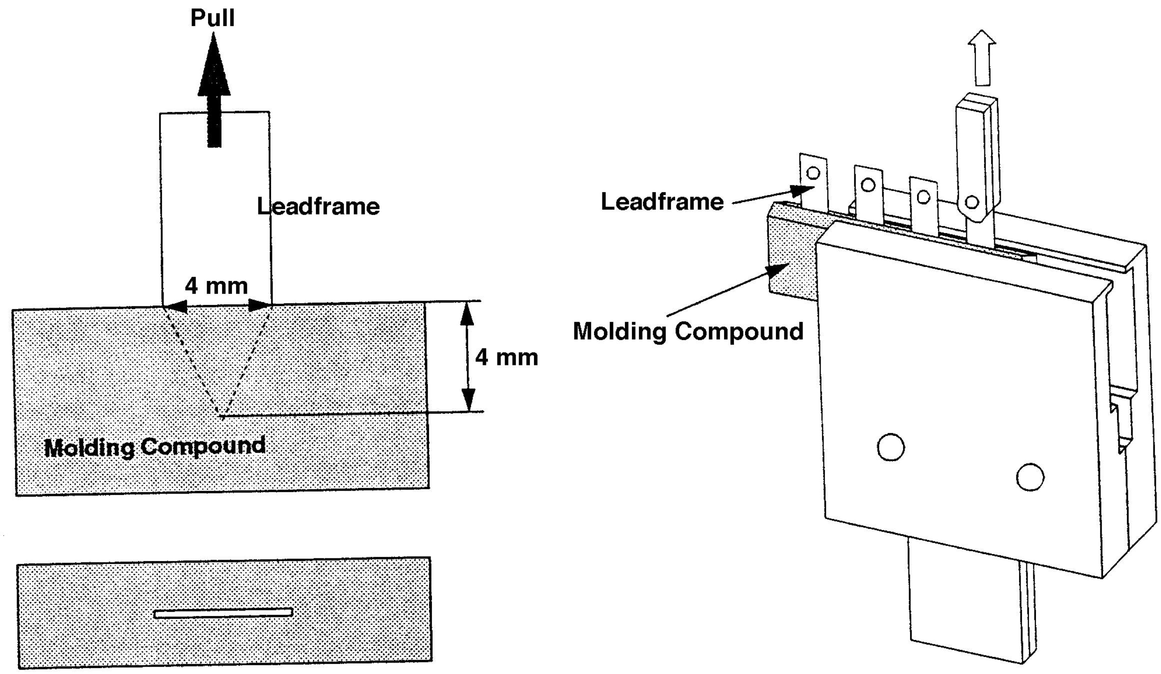

Figure 2
Sample for Pull Method

Adhesive Area	*Molding Compound Sample Thickness*
16 ± 0.8 mm^2 (both sides)	3.5–4.0 mm (equivalent to DIP 16 300 mil)

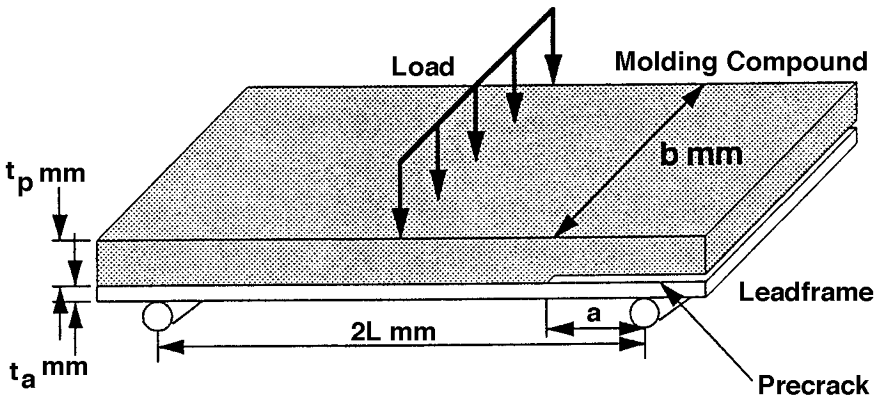

Figure 3
Sample for Three-Point Bending Method

	Molding Compound Thickness t_p *(mm)*	Leadframe Thickness t_a *(mm)*	Span 2L (mm)	Pre-Crack Length a (mm)	Sample Width b (mm)
Standard	1.5	0.25	45	10–15	6
Type A (for low adhesive strength)	0.8	0.2	35	8–10	4
Type B (for high temperature measurement)	4	0.5	50	10–15	6
Other Sample Types	The following equations should be satisfied $2L \geq 8\ (t_p + t_a)$ and $L - a \geq 2\ (t_p + t_a)$				

8 Sampling Plan

8.1 The sampling plan shall be agreed between customer and vendor. It is recommended that the following minimum sample sizes are used:

- *Shear Method* — Four (4) samples
- *Pull Method* — Four (4) samples
- *Three-Point Bending Method* — Three (3) samples in each direction

NOTE 1: Three-point bending method needs at least 2 samples to obtain adhesive strength.

9 Materials

9.1 Leadframe or appropriated sample from strip meeting dimensions for test.

9.2 Molding compound

10 Sample Preparation

10.1 *Leadframe Sample Preparation*

10.1.1 Process the leadframe samples through the various cleaning and heat cycles that would be normal for the leadframe under consideration as required.

NOTE 2: When this method is applied to copper leadframes, copper oxide on the surface shall be considered when results are interpreted.

10.2 Clean and condition the molds to provide well formed samples as required.

10.3 Set the molds to the specified temperature and record the temperature.

10.4 Set the transfer molding pressure, transfer time and cure time to the following recommended molding conditions. If the condition is not suitable for the material, the condition should be agreed between customer and vendor.

Molding condition	
Cure temperature	170 – 180 °C
Cure time	120 sec.
Molding pressure	6.8 – 7.8 MPa (70 – 80 kgf/cm^2)

10.5 Mold all the required samples.

10.6 Remove the samples from the molds.

NOTE 3: After removing the samples from the molds, natural cooling of the samples is recommended.

10.7 Post mold cure the samples at the following recommended conditions.

Post-cure condition	
Temperature	175 ± 5 °C
Time	4 – 8 hour

10.8 Store the samples and record the storage conditions.

10.9 Three-Point Bending Samples

10.9.1 In addition to the treatment mentioned in 10.1.1 and to facilitate cracking during the three point bending method, apply a thin layer of mold release to on end of the leadframe sample in order to form a "pre-crack" condition (i.e., the molding compound will not adhere to this section of the sample) (see Figure 3).

NOTE 4: It is recommended that toluen-based thermosetting silicone be used as a mold release agent to prevent molding process contamination.

11 Calibration

11.1 *Tensile Tester Calibration*

11.1.1 Calibrate the tensile tester in accordance with the manufacturer's instructions.

12 Test Procedure

12.1 *Shear Method*

12.1.1 Attach the sample to the tensile test such that shear may be applied.

12.1.2 Place the shear tool against the molding compound formation and initiate a load at a constant speed between 2–10 mm/min while recording the load and displacement.

12.1.3 Record the peak load before the sudden drop in applied load as the sample shears off the leadframe or the molding compound breaks.

NOTE 5: Disregard any results which have the appearance of sample slipping or shear tool riding over the molding compound.

12.2 *Pull Method*

12.2.1 Attach the sample to the tensile tester such that the leadframe may be pulled out of the molding compound with a vertical pull action.

12.2.2 Attach the pulling grips to the leadframe and initiate a load at a constant speed between 2–10 mm/min. while recording the load and displacement.

12.2.3 Record the peak load before the sudden drop in applied load as the sample is pulled from the molding compound samples.

NOTE 6: Disregard any results which have the appearance of slippage of the sample or pulling grips.

12.3 *Three-Point Bending Method*

12.3.1 Measurement of the pre-crack length

12.3.1.1 Measure the pre-crack length using an ultrasonic inspection technique (see Figure 4).

NOTE 7: The sample, in this case, is placed in the vessel with the leadframe side up, and then secured with an adhesive tape so that the water cannot penetrate into the interface area created by the mold release.

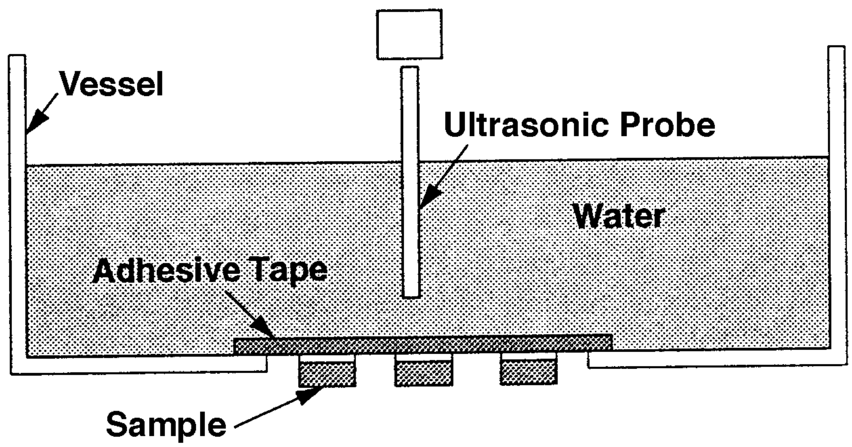

Figure 4
Measurement of Pre-Crack Length

12.3.2 *Test Procedure*

12.3.2.1 Attach support fixture and load wedge to the tensile tester.

12.3.2.2 Place the sample on the support fixture with the molded side up (see Figure 5).

NOTE 8: The support fixture tool should be located at a constant distance from the tip of pre-crack for every measurement.

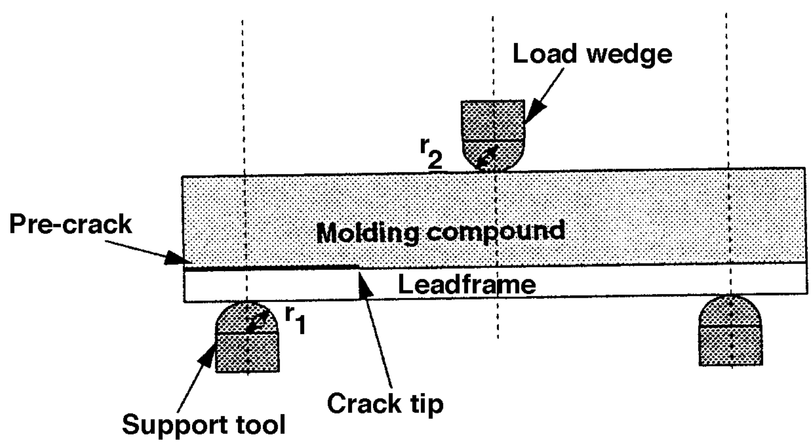

Figure 5
Sample Setup

Radius of support tool r_1	5 – 8 mm
Radius of load wedge r_2	2 – 5 mm

12.3.2.3 Place the load wedge in contact with the molded surface and initiate the loading at a constant speed between 2 – 10 mm/min while recording the load and displacement.

12.3.2.4 Record the peak load before the sudden drop in applied load.

12.3.2.5 Repeat the test with another sample which has the leadframe side up.

13 Calculation

13.1 *Shear and Pull Method*

13.1.1 The adhesive strength is calculated as follows:

Adhesive Strength (N/mm^2) = Peak Load (N)/Nominal Adhesive Area (mm^2)

13.2 *Three-Point Bending Method*

13.2.1 *Apparent Adhesive Strength* — Apparent adhesive strength including residual stress, is calculated using the stress intensity factor K_i as follows:

$$K_i = 4 \times 10^{-6} \cosh(\varepsilon\pi) \sqrt{\frac{G}{\frac{\kappa_p + 1}{\mu_p} + \frac{\kappa_a + 1}{\mu_a}}}$$

where

$$G = 3 \left[\frac{1}{t_p^3 E_p + t_p^3 E_a} - \frac{t_p E_p + t_a E_a}{k} \right] \frac{P^2 a^2}{2b^2}$$

$$k = 4 t_p t_a E_p E_a \left(t_p + t_a\right)^2 + \left(t_p^2 E_p + t_a^2 E_a\right)^2$$

$$\varepsilon = \frac{1}{2\pi} \ln \left\{ \frac{\frac{\kappa_p}{\mu_p} + \frac{1}{\mu_a}}{\frac{\kappa_a}{\mu_a} + \frac{1}{\mu_p}} \right\}$$

$$\kappa_j = 3 - 4\nu_j \qquad \text{(j = p or a)}$$

P : Peak load (N)

a : Pre - crack length (m)

b : Sample width (m)

t_p : Thickness of molding compound (m)

t_a : Thickness of leadframe (m)

E_p : Young's modulus of molding compound (Pa)

E_a : Young' s modulus of leadframe (Pa)

μ_p : Shear modulus of molding compound (Pa)

μ_a : Shear modulus of leadframe (Pa)

ν_p : Poisson's ratio of molding compound

ν_a : Poisson' s ratio of leadframe

13.2.2 *True Adhesive Strength* — The true adhesive strength (CKic) excluding residual stress, is calculated as follows:

$$K_{ic}\left(MPa\sqrt{m}\right)=\frac{K_{ib1}+K_{ib2}}{2}$$

where :

K_{ib1} : Apparent adhesive strength when testing is performed with molded side up ($MPa\sqrt{m}$)

K_{ib2} : Apparent adhesive strength when testing is performed with leadframe side up ($MPa\sqrt{m}$)

14 Report

14.1 The following items should be reported:

14.1.1 Leadframe

14.1.1.1 Material Designation

14.1.1.2 Thickness

14.1.1.3 Production Method (etching or stamping)

14.1.1.4 *Pre-Treatment* — In case that surface pre-treatment is necessary, the process and their condition should be reported as follows:

- Pre-treatment by plating
- Plating type
- Plating thickness

a. Post treatment after plating
- Corrosion prevention treatment
- Cleaning treatment
- Coupling material

b. Pre-treatment by heating
- Temperature
- Atmosphere
- Oven or Hot Plate

14.2 Molding Compound

14.2.1 Material Designation

14.3 Molding Compound Configuration and Dimension

14.4 Molding Condition

- Pre-heat condition (Temperature, Time)

- Molding condition (Cure temperature, Cure time, Injection speed, Injection pressure)

- Post-cure condition (Temperature, Time)

- Sample storage conditions

14.5 Measurement Method (Shear, Pull, or Three-point bending method)

14.6 Measurement Equipment

14.7 Adhesive Strength (maximum, minimum, average, and where possible, standard deviation, σ)

APPENDIX 1
SAMPLE OF MOLD FOR SHEAR METHOD

NOTE: This appendix was approved as an official part of SEMI G69 by full letter ballot procedure.

A mold to prepare samples for shear method is shown in Figure A1-1 as a sample.

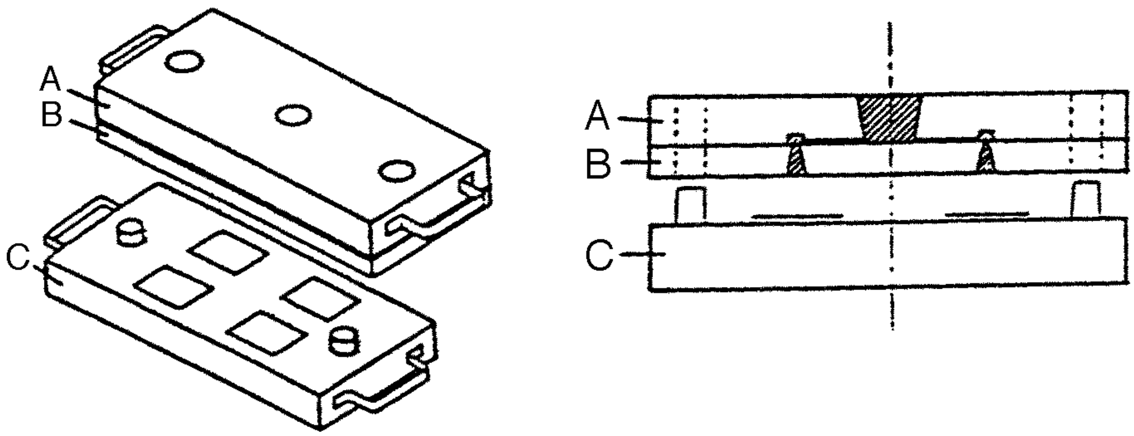

Figure A1-1
Mold Sample

APPENDIX 2
SAMPLE SIZE

NOTE: This appendix was approved as an official part of SEMI G69 by full letter ballot procedure.

Results of adhesive strength measurement made by some companies using the same leadframe material and molding compound are shown in Figure A2-1. The figures show that apparent adhesive strength decreases with an increase in adhesive area due to residual stress.

Sample size in this document was determined in consideration of the effect of residual stress and easiness of handling for samples.

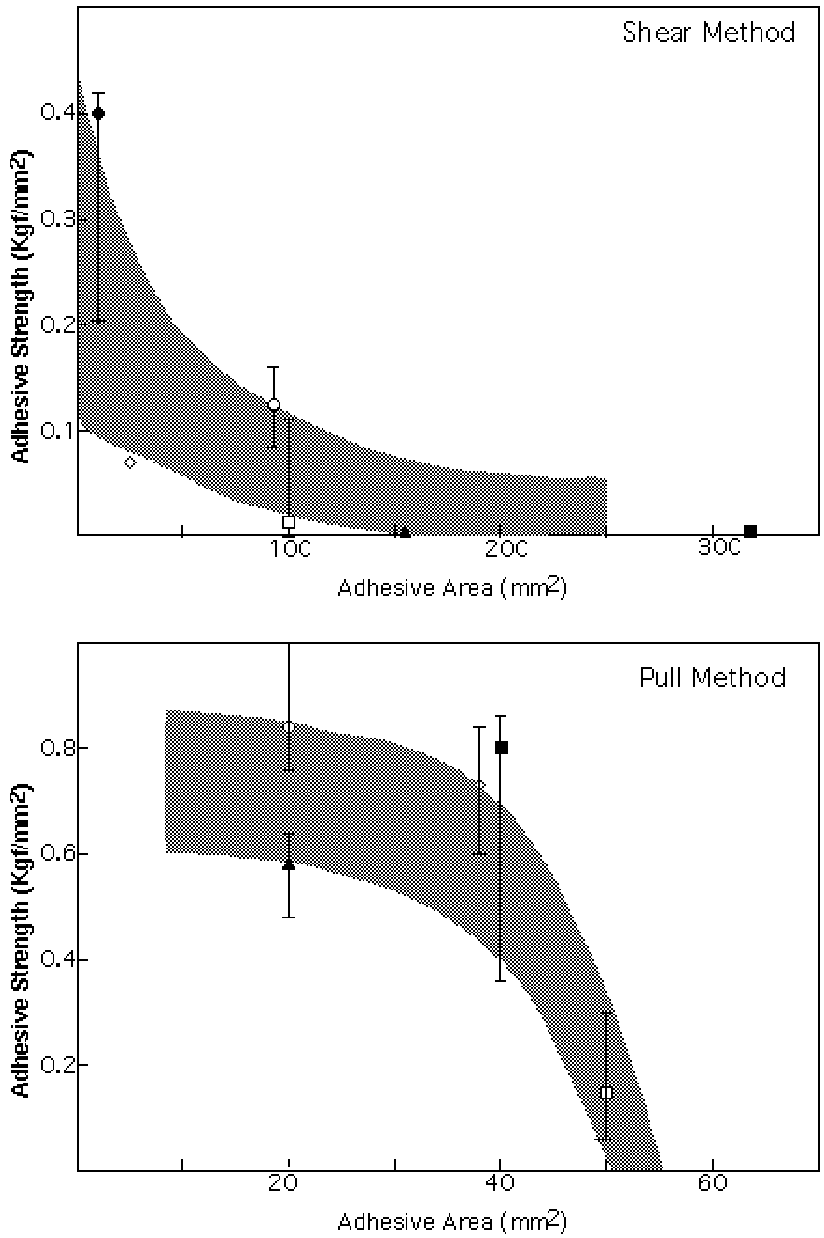

Figure A2-1
Dependence of Measurement Results on Sample Size

APPENDIX 3
EFFECTIVENESS OF RESIDUAL STRESS SEPARATION IN THREE-POINT BENDING METHOD

NOTE: This appendix was approved as an official part of SEMI G69 by full letter ballot procedure.

Since the three-point bending method can eliminate the effect of residual stress and also that of stress distribution on the interface (stress singularity at the adhering edges), the measurement results are almost independent of sample dimensions (Figure A3-1[1])). This method can evaluate both the true adhesive strength and the magnitude of residual stress, mainly due to the thermal expansion mismatch between materials, simultaneously (Figures A3-2 and A3-3[2])).

SEMI G70-0996
STANDARD FOR EQUIPMENT AND LEADFRAME FIXTURES FOR MEASUREMENT OF PLASTIC PACKAGE LEADFRAMES

1 Purpose

1.1 This standard describes the equipment and leadframe fixtures used for measurement of Z-axis dimensions of plastic package leadframes.

2 Scope

2.1 This standard mainly describes the equipment and leadframe fixture for measurement of leadframes that are ≤ 0.15 mm in thickness as used for TSOP and TQFP packages listed in group II in Table 1.

2.2 This standard also may be applied for leadframe of conventional packages which are ≥ 0.2 mm in thickness.

Table 1 Package Classification

Group I	*Group II*
	SSOP
DIP	TSOP
ZIP	TSSOP
SOJ	QFP
SOP	TQFP
QFJ (PLCC)	LQFP
	SVP

NOTE 1: Packages should be classified by EIAJ and JEDEC specifications.

3.2 *EIAJ Standard*[1]

ED-7411 — General Rules for the Preparation of Outline Drawings of Integrated Circuits, Packages Name and Code

3.3 *JEDEC Specifications*[2]

Pub. No. 95 — Registered and Standard Outlines for Semiconductor Devices

4 Terminology

NOTE 2: See SEMI G57 for leadframe features terminology.

4.1 *burr height* — Maximum height of burr above the plane which it protrudes. (See Figure 1.)

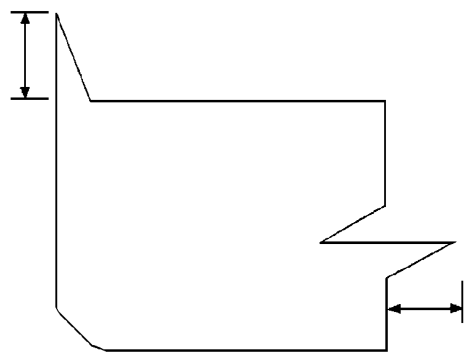

Figure 1
Burr Height

4.2 *coil set* — Longitudinal bowing of the leadframe strip length. (See Figure 2.)

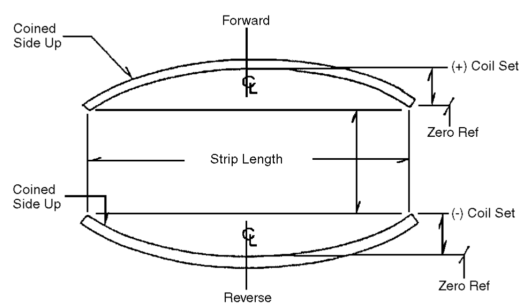

Figure 2
Coil Set

1 Standards of Electronic Industries Association of Japan, Tosho Bldg. 5F, 3-2-2 Marunouchi, Chiyoda-ku, Tokyo, Japan 100

2 JEDEC Standard, 2001 Eve Street, N.W., Washington DC, 20006

4.3 *coined depth* — The difference in height between the top surface of the coined area of an inner lead and the top surface of the coined area at the tip of the lead. Inner lead coining produces a flattened section of the lead that is suitable for wire bonding. (See Figure 3.)

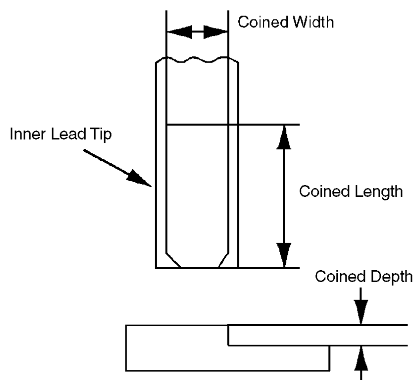

Figure 3
Coined Depth

4.4 *crossbow* — Transverse bowing of the leadframe. (See Figure 4.)

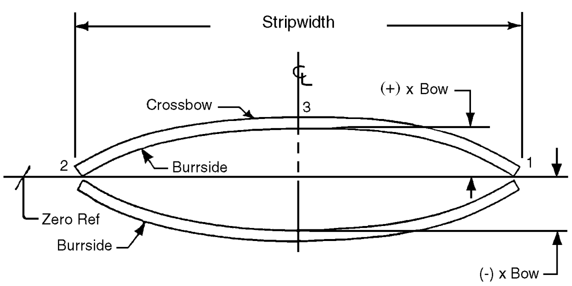

Figure 4
Crossbow

4.5 *die pad dimple* — A hollow formed in a die pad using a half-etching technique or stamping to improve the adhesive strength with the die or molding compound and to reduce the stress between the die pad and the die.

4.6 *die pad dimple depth* — The maximum depth of the dimple. (See Figure 5.)

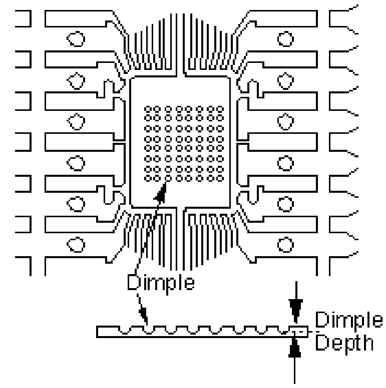

Figure 5
Die Pad Dimple Depth

4.7 *die pad flatness* — Deviation of the center point of die pad surface from a plane established by the four corner points of die pad. (See Figure 6.)

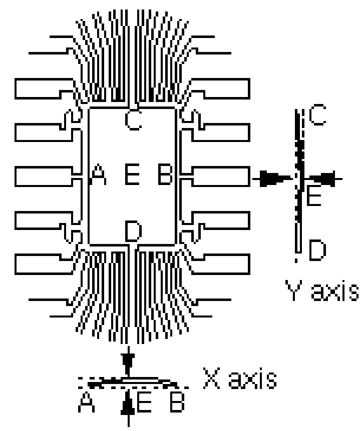

Figure 6
Die Pad Flatness

4.8 *die pad location* — Deviation of the center point of die pad surface from a plane established by the dam bars (see Figure 7).

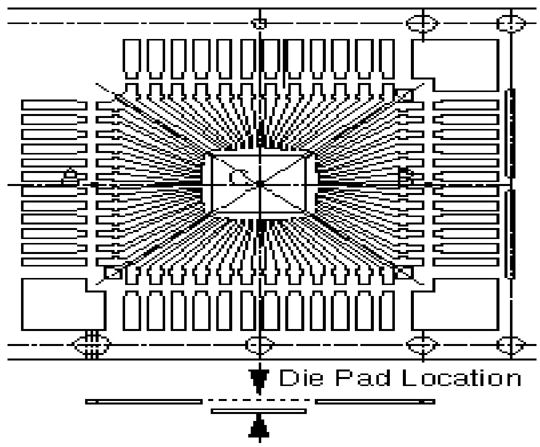

Figure 7
Die Pad Location

4.9 *die pad tilt* — Deviation of the plane of die pad from a condition parallel to the plane formed by the dam bars. (See Figure 8.)

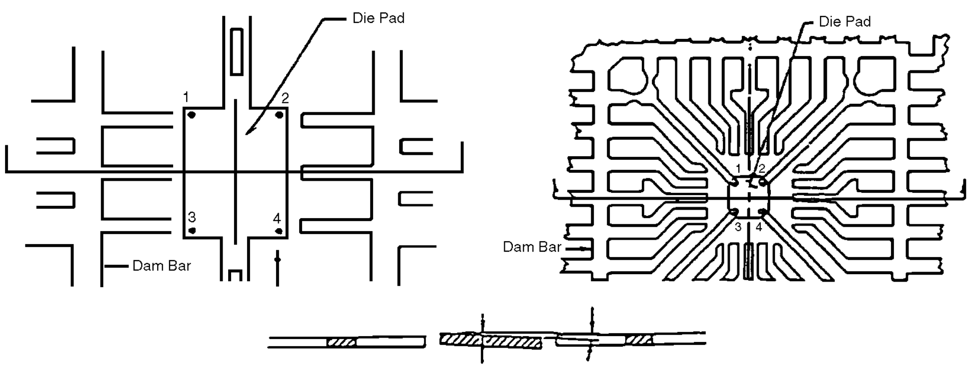

Figure 8
Die Pad Tilt

4.10 *downset depth* — (See Figure 9.)

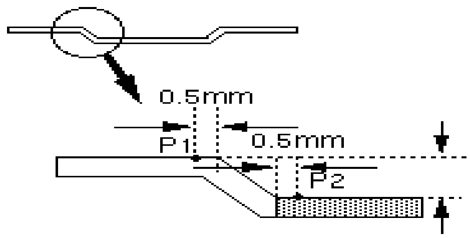

Figure 9
Downset Depth

NOTE 3: The measurement points P1 and P2 should be agreed between user and supplier.

4.11 *half-etch* — Some designed part or area of leadframe where the thickness is reduced by one side etching.

4.12 *half-etch depth* — The maximum depth of the half-etch. (See Figure 10.)

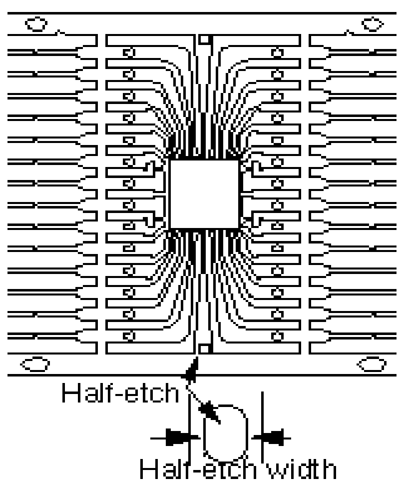

Figure 10
Half-Etch Depth

4.13 *lead coplanarity* — Total indicator reading difference of the lead tips in the Z direction. (See Figure 11.)

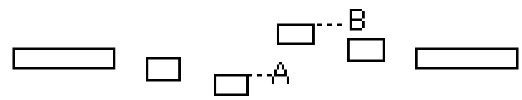

Figure 11
Lead Coplanarity

4.14 *lead planarity* — Total indicator reading of the lead tips in the Z direction relative to the datum formed by the dam bars. (See Figure 12.)

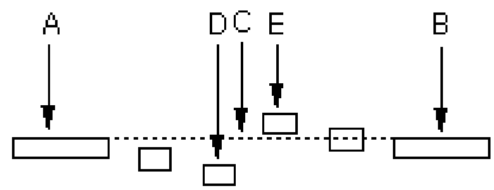

Figure 12
Lead Planarity

4.15 *lead lock groove* — A groove formed in leads using the half-etching technique or stamping to increase the adhesive strength of plastic molding compound to the leads and improve resistance to water intrusion into the package. (See Figure 13.)

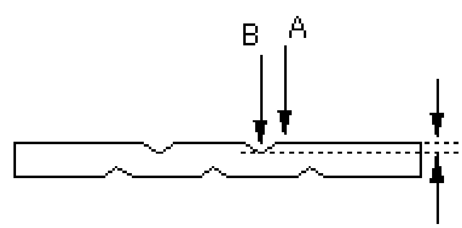

Figure 13
Lead Lock Groove

4.16 *lead lock groove depth* — The maximum depth of the groove.

4.17 *lead tilt* — Deviation of the plane of coined area from a condition parallel to the plane formed by the dam bars. (See Figure 14.)

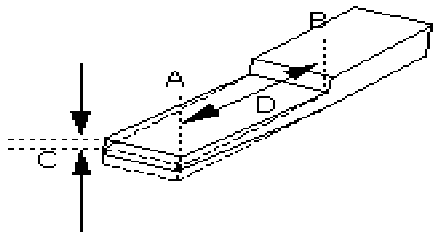

Figure 14
Lead Tilt

4.18 *leadframe twist* — Angular rotation of one end of the leadframe or strip with reference to the other end. (See Figure 15.)

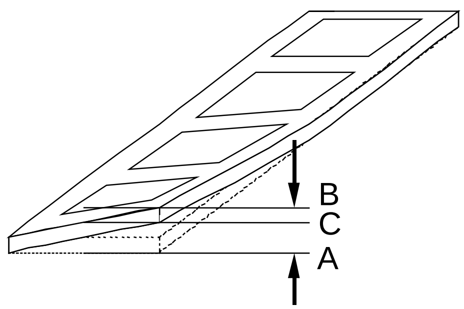

Figure 15
Leadframe Twist

5 Equipment

5.1 *Measurement Equipment* — The equipment and required accuracy used for the measurements are shown in Table 2.

Table 2 Measurement Equipment

Type	*Equipment*	*Minimum Reading*	*Accuracy (2σ)*
A	Height measurement equipment with non-contact method	0.1 µm	1 µm
B		1 µm	4 µm
C	Clearance gage	10 µm	-
D	Scanning probe microscope	0.1 µm	-

5.2 *Leadframe Fixtures* — Leadframe fixtures are shown in Figures 16 – 20. The materials, dimensions, and accuracy shall be agreed between the vendor and customer.

SPECIFICATION FOR BARCODE MARKING OF INTERMEDIATE CONTAINERS FOR PACKAGING MATERIALS

1 Purpose

1.1 This specification describes a common format, content, size, and location for printed, machine-readable labels on an intermediate container of materials used for semiconductor packaging.

1.2 This specification provides for a smooth transition from existing traceability and labeling procedures to a comprehensive, unified system envisioned for the future.

2 Scope

2.1 This document applies to the following packaging materials:

- Leadframe
- Molding compound
- Bonding wire
- Die attach materials

2.2 This document applies to only the intermediate container. Barcode specification for shipping pack is referred to EIA 556A or EIAJ barcode specification.

2.3 This document does not apply to product package label.

NOTE 1: There are requests for labeling on product packages from the customers. However, task force concluded that the product package label was not included in scope of the specification because of limitation of area to be labeled on the package. For further activity, two-dimensional barcode symbol may be needed to standardize the barcode marking specification for product packages.

3.3 *EIA Specification*[3]

EIA 556A — Outer Shipping Container Bar Code Label System

3.4 *EIAJ Specification*[4]

EIAJ — Standard, Bar Code Label System

4 Terminology

4.1 Many items relating to barcode technology are defined in EIA 556, Appendix Definitions, and EIAJ Bar Code Label Systems, Appendix A.

4.1.1 *intermediate container* — A container housing one or more product packages for the purpose of product/ order segregation in a shipping container.

4.1.2 *product package* — The first tie, wrap, or container to a single item or quantity thereof that constitutes a complete identifiable pack. Product package may be packaged together or a group of the parts packaged together. Product package is also called unit pack.

4.1.3 *shipping pack* — A package or shipping container/ final container that is of sufficient strength to be used in commerce for packing, storing, and transporting products (see Figure 1).

4.2 Package forms for each material type are defined in Table 1.

5 Ordering Information

5.1 Purchase orders for the materials furnished in an intermediate package to the specification shall be include the following:

5.1.1 Content of message characters for customer product ID.

5.1.2 User-specified data, if required.

5.2 In addition, the following optional items may be specified.

5.2.1 Label location on the intermediate container.

5.2.2 Label size, if a label larger than the specified size in this specification.

6 Content of Data Field

6.1 The label shall include vendor field and customer field.

6.2 The customer field shall contain three data fields for barcode symbols. Each data field shall contain a maximum 17 message in addition to the start and stop characters. The content of the barcode symbol is shown in Table 2.

6.2.1 The upper data field shall contain a barcode symbol with customer product ID which consists of maximum 15 characters, preceded by a “P”, the data identifier for this item as specified in ANSI/FACT-1.

6.2.2 The middle data field shall contain a barcode symbol with lot number which consists of maximum 12 characters, preceded by a “1T”, the data identifier for this item as specified in ANSI/FACT-1.

6.2.3 The lower data field shall contain quantity and the production date concatenated into a single barcode symbol. Quantity is indicated by maximum 7 characters, preceded by a “7Q”, the data identifier for this item as specified in ANSI/FACT-1. The production date is indicated by 6 characters, preceded by a “D”, the data identifier for this item as specified in ANSI/FACT-1. The quantity and the production date are separated by a space.

6.2.3.1 Quantity indicated in this field shall be quantity in the intermediate container. The unit of measure should follow the quantity data to indicate what unit of measure is being used in the quantity count. The Unit uses 2 characters listed in Appendix D of ANSI/FACT1.

6.2.3.2 Quantity that are not filled by a message characters shall contain hyphen (-) as a place saver to that the symbol always has exactly 7 characters.

6.3 Vendor company name and its logo mark; supplier’s ID may be included in the supplier’s field.

Table 1

	Explanation	*Data Identifier*	*No. of Characters*
Part No.	Customer part number. The number is assigned by the customer in the ordering information.	P	15 max.
Lot No.	Lot number is assigned by the supplier to identify or trace a unique group of the entries.	1T	12 max.
Quantity	Quantity and unit within the package. The unit uses characters listed in Appendix D of ANSI/FACT1.	7Q	7
Production Data	The Date of production. The date is shown by "YYMMDD".	D	6
Supplier's Field	Supplier's name, supplier's company logo mark, supplier's code (agreed between supplier and customer) country, etc.	-	(Option)

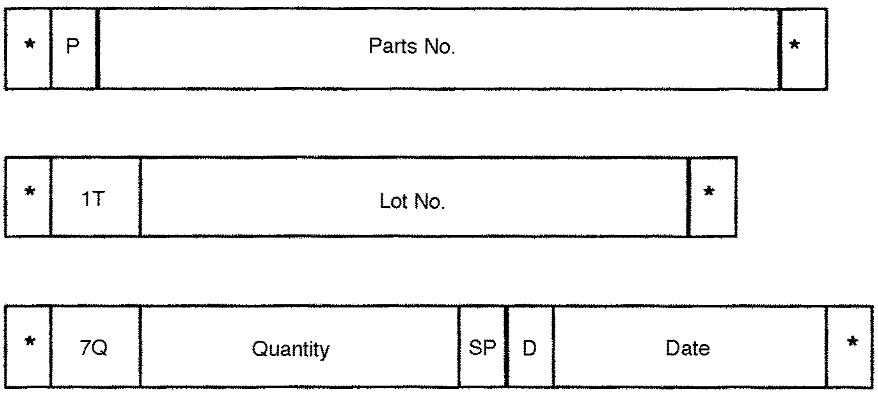

Figure 2
Barcode Arrangement

7 Barcode Character

7.1 The barcode characters specified in AIM USS-39 shall be used.

7.2 *Character Set* — The Code 39 character set consists of 43 characters: 0–9, A–Z, ., $, /, %, and space. In addition, an asterisk (*) is used only for both the stop and stop characters.

7.3 *Print Quality* — The Code 39 print quality shall be B/03/630 or better in accordance with ANSI X3.182. To assure reading efficiency, the minimum reflectance of the quiet zones shall be 60%, the minimum reflectance of spaces shall be 51%, and the maximum reflectance of bars shall be 10%.

7.4 *Symbol Dimensions* — Barcode symbol dimensions shall be as listed in Table 2.

Table 2 Symbol Dimensions

Code 39	*Dimension*
Narrow Element Width	0.250 mm
Wide Element Width	0.625 mm (Element Width Ratio 1:2.5)
Space between Characters	0.250 mm
Character Height	8.0 mm
Quiet Zone	5.0 mm (after and before barcode symbol)
Space between Barcode Field	5.0 mm

8 Human-Readable Interpretation (HRI) Symbols

8.1 Each barcode symbol data field on the customer field shall have an associated human-readable data field either immediately above or below it.

8.1.1 Start and stop characters shall not be included, but the data field identifier shall be included.

8.2 The height of human-readable characters shall be 3.0 mm.

8.3 The spaces above and below the human-readable characters shall be 1.0 mm.

9 Dimensions and Placement of Data Field on Label

9.1 The size of barcode label shall be 42 mm in height and 120 mm in wide.

9.2 The dimensions and placement of data field on label are shown in Figure 3.

9.3 The barcode and human-readable characters shall be placed within this area of the label as indicated in Figure 3.

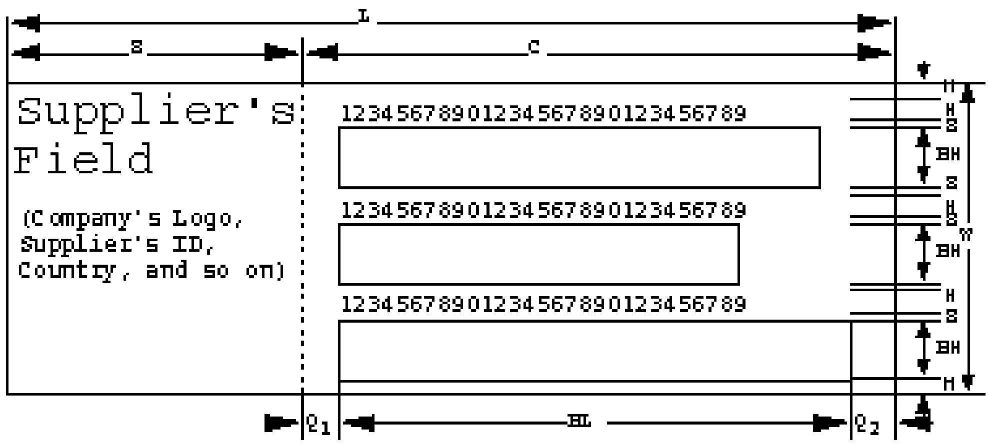

Figure 3
Dimensions and Placement of Data Field on Label

Horizontal Dimension	*Value (mm)*	*Vertical Dimension*	*Value (mm)*
L	120.0	W	40
S	40.0	M	2.0
C	80.0	H	3.0
BL	68.625	S	1.0
Q1	5.0	BH	8.0
Q2	6.375		

10 Barcode Label Location

The barcode label shall be located on the end of the packages for easy identification when the packages are temporarily stored in the storage shelf.

11 Label Material and Adhesive

11.1 Label material should not generate particles.

11.2 Label adhesive should not prohibit recyclability of the shipping packages.

Material	Unit Pack	Intermediate Container
Leadframe 	The leadframes of specified quantity are packaged in a hardcase or wrapped by paper such as OP sheet. 	The unit packs of specified number are packaged in a box, a sterol case, a plastic case and etc. Molding Compound 		Molding compound of powder or tablet is wrapped by plastic bag and then it is packaged in a box or a drum. Die Attach Materials	Die attach material of specified quantity is poured into a syringe and the syringe is corked up. Or die attach material is poured into a plastic jar or a bottle. 	The unit packs of specified number are packaged in a box, a carton case, a plastic case and a plastic bag. Bonding Wire	Bonding wire is winded into a spool and then each spool is packaged in a clear plastic case. 	The unit packs of specified number are packaged in a box or a plastic case. 
Figure 4
Definition of Packaging Forms for Leadframe, Molding Compound, Die Attach Material,and Bonding Wire

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI G72-0997
SPECIFICATION FOR BALL GRID ARRAY DESIGN LIBRARY

1 Purpose

The purpose of this specification is to promote industry use of common BGA designs that may be distinguished by their form, fit, function, and reliability requirements and to record designs by category that meet these requirements.

2 Scope

2.1 This document provides a library of company-sponsored BGA designs for the purpose of promoting the use of these common designs and to minimize the unnecessary proliferation of new designs. New designs will be added as they become sponsored by and approved by member companies.

2.2 This library shall include ceramic, plastic, tape, metal and other (as new categories of designs are identified and added to this specification) BGA designs that are fully compliant with existing JEDEC-registered or standard mechanical outlines. Proposals for new designs may be balloted in parallel with congruent JEDEC registrations or standards, but will not be published in this library until such registration and/or standard is an approved JEDEC outline.

2.3 Controlling dimensions are metric (Systems International units).

3 Referenced Documents

3.1 *SEMI Documents*

SEMI International Standards Compilation of Terms

Regulations Governing SEMI Standards Committees

3.2 *ASME* [1]

ASME Y14.5M-94 — Dimensioning and Tolerancing

3.3 *EIA/JEDEC* [2]

EIA JEDEC Publication 95 — Registered and Standard Outlines for Semiconductor Devices

JEDEC BGA Design Guide 95-1 — Section 14

J-*STD-020* —

JESD 22-A113 — Preconditioning of Plastic Surface Mount Devices Prior to Reliability Testing

4 Terminology

4.1 *ball grid array (BGA) package* — A square or rectangular substrate package with an array of metallic balls on one surface of the package. The metallic balls form the electrical and mechanical connection between the package and the PC board or socket.

4.2 *column grid array* — Same as ball grid array except that metallic columns are used in place of the metallic balls for the electrical and mechanical interconnection between the package and the PC board.

NOTE 1: In the text of this specification, whenever ball grids are mentioned, a reference to column grids is also implied.

4.3 *wire bond ring* — Metalized area in the shape of a complete or partial ring surrounding the die mounting area intended for group electrical interconnections.

5 Ordering Information

5.1 *Order of Precedence* — To avoid conflicts, the order of precedence when ordering ball grid array substrates or assembled packages when using BGA Library Designs from this specification shall be as follows:

a. Purchase Order

b. Customer BGA Drawing

c. BGA Library Design from this specification

d. Referenced Documents from Section 3.0

e. Other related documents

6 General Design Characteristics Listing Format

6.1 Each design addition to this library shall include a general design characteristics description which shall be listed in Appendix 1 of this specification and also be formatted on top of the title block for each design drawing.

6.1.1 Description listings in the General Design Characteristics, Appendix 1 shall be organized into category sections: Plastic, Ceramic, Tape, Metal, or Other.

6.1.2 These descriptions shall be listed across a row of characteristics classification columns and may determine the uniqueness of each design.

1 American Society of Mechanical Engineers, 22 Law Drive, P.O. Box 2900, Fairfield, New Jersey 07007-2900.

2 Electronic Industries Association, Joint Electron Device Engineering Council, 2500 Wilson Blvd., Arlington, VA 22201, (703) 907-7560.

6.2 The characteristics classification columns may be used in a data base format to sort the design listings sequentially, top to bottom according to their sequential listing by column, left to right, in the following order. These listings and their descriptive designations are as follows:

6.2.1 *Ball Count* — List the actual number of balls on the package.

6.2.2 *Signal I/O* — List the available balls for individual signal I/O. This does not include balls that are interconnected with other balls, bond rings, power or ground planes or other electrically interconnected features, such as die attach pads.

6.2.3 *Body Size* — List ##×## (i.e., 27×27) to represent JEDEC Publication 95 registration values in millimeters for "D" & "E" nominal body dimensions.

6.2.4 *Pitch* — List number representing JEDEC Publication 95 registration values in millimeters for the "e" pitch dimension.

6.2.5 *Matrix* — List ##×## (i.e., 20×20) to represent JEDEC Publication 95 matrix values determined by the number of balls on the outside row and column.

6.2.6 *Array* — List either Full, Staggered, Peripheral, or Depopulated:

- Full — Completely filled matrix, as defined by the JEDEC Publication 95 registration and variation shown for each design.
- Staggered — A full matrix which has been depopulated by every other ball in each row and column.
- Peripheral — Balls missing in the center of the BGA package. Outer rows of the matrix are fully populated.
- Depopulated — Any variation not described by full, staggered, or peripheral as described above.

NOTE 2: Any of the above matrix designs may have one ball missing from its defined matrix description above, for purposes of package orientation, and still be classified according to that description.

6.2.7 *Thermal Enhancement* — List #×# (i.e., 6×6) or "Cu Slug," to designate either a specific matrix of balls for thermal enhancement purposes or copper heat slug for the same. Other metal slugs may be listed by their appropriate metal constituent. List "N/A" if the design has no thermal enhancement.

6.2.8 *Profile Height* — List the dimension of the nominal profile height in millimeters.

6.2.9 *Package Cavity Orientation* — List either up or down with reference to the board to which the package design would be surfaced mounted (a cavity facing the board would be cavity, down).

6.2.10 *Wire bond Rings* — List the number of wire-bond rings. If the design has no rings, list "N/A."

6.2.11 *Substrate Materials* — Generic description of the materials the substrate is made from, excepting the electrical trace and solder mask materials.

6.2.12 *Metal Layers* — The number of metal interconnect layers in the BGA substrate. List a(bscpdg) where:

a= total number of metal layers
b= number of signal layers
s= signal layer designator
c= number of power layers
p= power layer designator
d= number of ground layers
g= ground layer designator

e.g., 4(2slplg) would have 4 total layers made up of 2 signal layers and 1 power and ground layer each.

6.2.13 *Die Interconnect* — Interconnect method for electrically connecting the die to the package. Normal methods include wire bond, flip chip and TAB.

6.2.14 *Encapsulation Design* — Design description. Normal categories are over-molded, liquid encapsulant or lid.

6.2.15 *Encapsulation Material* — General description of the material used to mechanically cover or encapsulate the chip or die. The materials normally used are epoxy for over-molding or liquid encapsulant designs, metal, ceramic or laminate for lid designs.

6.2.16 *Ball Composition* — Description of the material and composition of the ball. Should include a percentage of tin/lead or other metals, if solder ball (i.e., 63/37 Sn/Pb, alloy coated, copper or plastic).

6.2.17 *JEDEC Designation* — List JEDEC designation from its Publication 95. This should include registration or standard number, the specific variation and revision designations (i.e., MO-151, BAE-1, B) (this indicates Issue, Revision B).

6.2.18 *Preconditioning Level* — The specified JEDEC, J-STD-020 moisture sensitivity performance level requirement. This should also include a reference to the revision of the J-STD-020 specification (e.g., Level 4, Revision A).

NOTE 3: JEDEC, JESD 22 - A113 specifies the moisture preconditioning requirement for the moisture test to J-STD-020.

6.2.19 *Design Number* — SEMI assigned design number for this design. The numbers will be assigned by SEMI (upon ballot approval) and will be an alphanumeric designation in sequential order as follows:

- Plastic BGA Designs will be assigned PBDxxxx designations, where xxxx numbers are sequentially assigned beginning with 0001.
- Ceramic BGA Designs will be assigned CBDxxxx designations, where xxxx numbers are sequentially assigned beginning with 0001.
- Tape BGA Designs will be assigned TBDxxxx designations, where xxxx numbers are sequentially assigned beginning with 0001.
- Metal BGA Designs will be assigned MBDxxxx designations, where xxxx numbers are sequentially assigned beginning with 0001.

NOTE 4: The second letter designator may be assigned as either a B or C to designate whether the design is a ball grid or column grid array.

6.3 Appendix 1 is an example of a general design characteristics listing for a plastic BGA.

7 Drawing Format

7.1 Appendix 2 is an example of the drawing format.

7.2 Dimensions

7.2.1 All dimensions, and tolerances shown or not shown shall be in conformance with the JEDEC Publication 95 registration or standard outline referenced by the designation shown in the general design characteristics listing for each design.

7.2.2 Nominal and basic dimensions shown in the drawing may have minimum and maximum values and associated tolerances that may be referenced in JEDEC Publication 95 according to the registration designation shown in the general design characteristics listing for each design.

7.2.3 Dimension values will be shown on the drawing, not in a table.

7.2.4 Basic dimensions only will be used for package length and width dimensions (JEDEC “D” and “E” dimensions), the ball pitch (JEDEC “e” dimension), and the JEDEC “s” dimension.

7.2.5 The JEDEC “s” dimension will be shown only for even row matrix designs. Odd row matrix designs will only reference a centerline coincident with the center of the center row of balls.

7.2.6 A nominal and maximum dimension for the overall profile height (JEDEC dimension A) will be shown. The maximum dimension shown may be less than but may not exceed that maximum dimension designated by the JEDEC Publication 95 registration reference for this design.

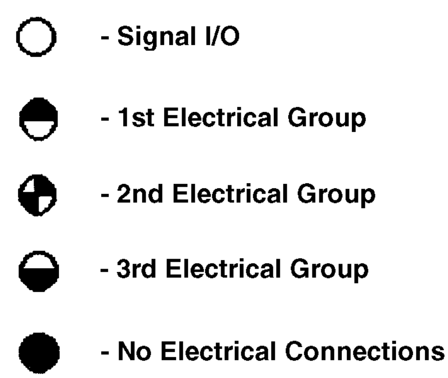
7.2.7 Reference or nominal dimensions may be shown for the package body thickness, substrate thickness, encapsulation layer or lid thickness, and the standoff height dimensions.

7.3 *Ball Configurations*

7.3.1 Retain and show the JEDEC method for numbering the ball columns and rows.

7.3.2 The ball configuration drawing will show the exact number and location of balls for each design.

7.3.3 The following symbols are to be used for designating the electrical interconnections or lack thereof for the balls shown on the design drawing:



7.3.4 Notes on the drawing will show the above symbols and designations for each of the electrical groups used with each specific design.

7.4 The orientation of the internal bond finger peripheral pad locations to the external package will be illustrated by a top view of the package which indicates the Pad 1 and A1 ball locations relative to the package sides, 1–4, for all designs using wire bond or peripheral die interconnection layout schemes.

7.4.1 For peripherally bonded layouts, the Pad 1 bond finger will always be located in the same corner as the A1 ball, and the pads will be sequentially numbered, for purposes of the net list, in a counterclockwise rotation as viewed from the die side of the substrate. This applies to all cavity orientations (cavity up or down).

7.5 The design drawing must have a BGA design title, a BGA design number, a revision number, the date of issue and a design page number shown at the bottom of each page.

7.6 The design drawing shall include a general design characteristics description which will also be listed in Appendix 1 of this specification. This description should be re-formatted on top of the title block for each design drawing and may exclude the BGA design number, which will be shown in the title block at the bottom of the page.

8 Net List Format

8.1 Appendix 3 is an example of the net list format including all reference notes.

8.2 The net list shall follow the drawing as part of the BGA design and shall be formatted in columns as follows:

- Column 1: Lists BGA wire bond pad and wire bond ring numbers.
- Column 2: Lists solder ball connections.
- Column 3: Open column for later use in listing die wire bond pad numbers.
- Column 4: Open column for later use in listing die I/O name.
- Column 5: Lists package side location number of bond pad connection.
- Column 6: Lists note reference numbers.

8.2.1 The listing of ball numbers should begin with A1, and continue in sequential order (i.e., A1, A2...An, B1, B2...Bn, C1, C2...Cn).

8.2.2 Wire bond ring numbers in the first column should be designated in sequential order from inner most to outermost (i.e., w/b ring 1, w/b ring 2, and w/b ring 3) if there are three separate rings. The innermost ring being w/b ring 1 and the outermost ring being w/b ring 3.

8.3 Notes in the net list will reference each of the electrical groups used with that specific design and will list all additional associated interconnections for those groups, if any.

8.4 Notes may consist of explanation of bond finger orientation relative to top view illustration on drawing for reference (independent of general specification explanations) of net list to BGA design drawing.

8.5 Notes may also consist of applications warnings or guidelines to insure correct use of the net list with the design drawing.

8.6 All pages of net list must have a BGA design title, a BGA design number, a revision number, the date of issue and a design page number shown at the top of each page.

9 Addition of Registrations

9.1 This specification will be published initially in a loose leaf notebook and as package design registrations are approved, they will be individually published in a loose leaf format for easy access into the original notebook by the publication owner.

9.2 Each new registration must be added to the specification using the SEMI standard balloting procedures. Refer to the "Regulations Governing SEMI Standards Committees" publication.

NOTES:

*1. Please refer to Notes column for explanations of wirebond (w/b) rings. PBGA Wirebond Pads are numbered counter clockwise, starting with Pad #1 in the upper left hand corner. Please refer to Top View of package for package side #1, 2, 3, or 4 (Figure 1).

*2. Metallized wirebond (w/b) ring 2 surrounds die attach area for wirebonding to electrically common die pads and electrical connection with solder balls designated by 2nd Electrical Group symbol on BGA Design Library Drawing (Figure 1).

*3. Metallized wirebond (w/b) ring 1 surrounds die attach area for wirebonding to electrically common die pads and electrical connection with both die attach pad and solder balls designated by 1st Electrical Group symbol on BGA Design Library Drawing (Figure 1).

*4. If the number of signal Die Wirebond Pads (not including Electrical Groups) total less than 231, the total number may be divided by 4 and wirebond placement centered on each package side.

*5. Thermal enhancement of 6 x 6 solder balls.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

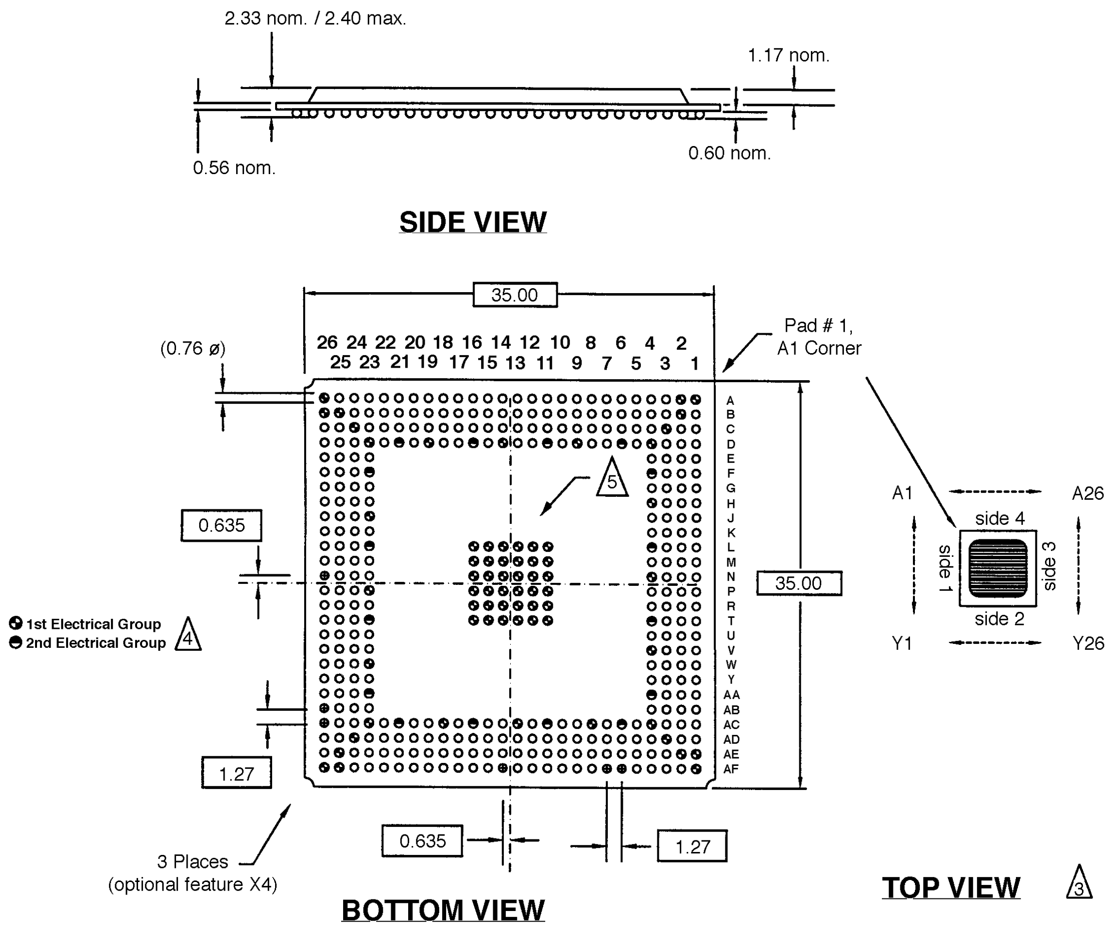
BT Laminate	2(2S0P0G)	wirebond	overmolded	epoxy	63/37 Sn/Pb	MO-151 BAR-2, B	Level 3,Rev 0	PBD0002	G72.2



NOTES:

1. Refer to JEDEC MO-151 Issue B Variation BAR-2 for all dimensions and tolerances not shown. This design must be in full conformance with the referenced JEDEC outline drawing.

2. All dimensions are in millimeters unless otherwise noted.

3 (△) Top View illustrates the relationship between external package features, internal wirebond pad number 1, and side 1, 2, 3, and 4 of the internal wirebond pads. Please see SEMI Standard BGA Design Netlist for specific electrical connections and more detailed notes.

4 (△) Solder Balls with this symbol have common electrical connections, and may be connected to other internal package features. Please see SEMI Standard BGA Design Netlist for other specific electrical connections.

5 (△) Thermal enhancement of 6 x 6 solder balls shown. Please see SEMI Standard BGA Design Netlist for other specific electrical connections.

NOTES:

*1. Please refer to Notes column for explanations of wirebond (w/b) rings. PBGA Wirebond Pads are numbered counter clockwise, starting with Pad #1 in the upper left hand corner. Please refer to Top View of package for package side #1, 2, 3, or 4 (Figure 1).

*2. Metallized wirebond (w/b) ring 2 surrounds die attach area for wirebonding to electrically common die pads and electrical connection with solder balls designated by 2nd Electrical Group symbol on BGA Design Library Drawing (Figure 1).

*3. Metallized wirebond (w/b) ring 1 surrounds die attach area for wirebonding to electrically common die pads and electrical connection with both die attach pad and solder balls designated by 1st Electrical Group symbol on BGA Design Library Drawing (Figure 1).

*4. If the number of signal Die Wirebond Pads (not including Electrical Groups) total less than 304, the total number may be divided by 4 and wirebond placement centered on each package side.

*5. Thermal enhancement of 6 x 6 solder balls.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. SEMI G73-0997
TEST METHOD FOR PULL STRENGTH FOR WIRE BONDING

1 Purpose

This standard defines the pull strength test method for wire bonding.

2 Scope

2.1 This standard defines the destructive pull strength test method and its criterion for evaluating pull strength of wire bonds connecting two points, connected by using ball bonding technique.

2.2 This standard can be applied to measure wires whose diameter is less than 100 microns.

3 Referenced Documents

NOTE: As listed or revised, all documents cited shall be the latest publications of adopted standards.

3.1 *Military Standard* [1]

MIL-STD-883D — Test Methods and Procedures for Microelectronics

4 Terminology

4.1 *hook* — L or similar-shaped tool for hooking a wire for pull test.

5 Apparatus

5.1 Pull Tester or equivalent equipment

5.1.1 Enough stroke to break a wire.

5.1.2 *Accuracy* — Within ± 0.5% to the full scale of load cell.

5.1.3 *Pull Speed* — Constant speed.

5.1.4 *Hooks* — Between 25—100 microns in diameter.

NOTE 1: Hook must be made of material strong enough to break wire while testing but not with a small diameter so as to cut through the wire.

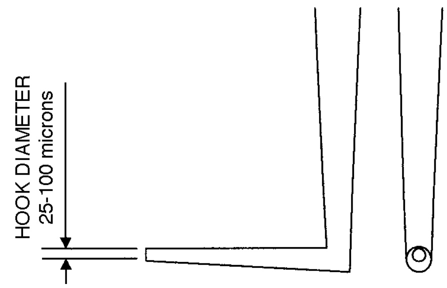

Figure 1
Hook Diameter

5.1.5 Calibration of equipment must be simple enough so that users can calibrate it easily. Instructions for calibration should be described in equipment manual.

6 Sampling

Measure at least 30 points from at least 2 devices. From each side of the devices, select the same number of wires randomly.

7 Calibration and Standardization

7.1 *Calibration Method*

7.1.1 Calibration of equipment should be done using official and traceable weights.

7.1.2 Display the weight and verify whether the results are within the equipment's accuracy.

7.1.3 Repeat the measurement using other weights to verify repeatability and linearity of the calibration.

7.2 *Interval of Calibration*

7.2.1 Calibrate at regular intervals at least once a year.

7.2.2 Calibration must be able to be done just before testing when necessary or specifically instructed.

8 Procedure

8.1 Fix samples using a clamper or adhesive, so that the sample will not float, without applying excessive stress to the wire.

8.2 Set pull speed to 0.5 mm/sec while measuring.

8.3 Insert the hook under the bonded wire between the top of the first bonding and the center of the loop.

NOTE 2: Select hook position accordingly to package, wiring condition, and wire diameter.

1 Military Standards, Naval Publications and Form Center, 5801 Tabor Avenue, Philadelphia, PA 19120.

NOTE 3: Place the hook perpendicular to wiring direction if there is no specific instruction.

NOTE 4: Do not measure damaged or deformed wire.

8.4 Pull the hook perpendicular to die/substrate.

8.5 Record the force that breaks the wire as the pull strength.

8.6 Repeat the measurement on another wire.

NOTE 5: Do not change the position while testing the same samples.

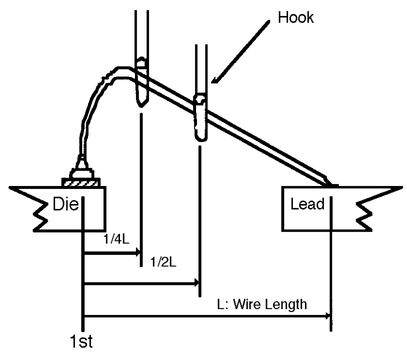

Figure 2
Hook Position

9 Report

Report of the pull test must contain the following information.

9.1 *Pull Strength*

9.2 *Breaking Mode* — Choose the closest position from Figure 3 below and represent the broken position by number or alphabet in the figure.

Breaking Mode (Report in number or alphabet)

1,A: The first bond

2,B: The first bond neck

3,C: Loop

4,D: The second bond neck

5,E: The second bond

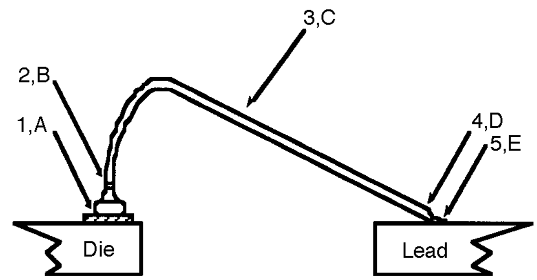

Figure 3
Breaking Mode

9.3 *Hook Position*

9.4 *Rejection* — Criterion of each semiconductor manufacturer to each product. Refer to "Minimum Strength" of the attached MIL-STD-883D.

SEMI G74-0699
SPECIFICATION FOR TAPE FRAME FOR 300 mm WAFERS

This specification was technically approved by the Global Assembly & Packaging Committee and is the direct responsibility of the Japanese Packaging Committee. Current edition approved by the Japanese Regional Standards Committee on March 17, 1999. Initially available at www.semi.org May 1999; to be published June 1999. Originally published June 1998; previously published September 1998.

1 Purpose

1.1 The purpose of this document is to standardize the specifications for 300 mm wafer tape frames used between the dicing process and the die-bonding process.

2 Scope

2.1 This standard documents the dimensions, characteristics, and measurement methods for 300 mm wafer tape frames.

2.2 This standard can be used as the specification sheet for tape frame upon purchasing.

2.3 This standard uses the SI unit system.

3 Referenced Documents

NOTE: As listed or revised, all documents cited shall be the latest publications of adopted standards.

3.1 *ANSI Standard*[1]

ANSI/ASME B46.1 — Surface Texture (Surface Roughness, Waviness, and Lay)

3.2 *ISO Standards*[2]

ISO4287 Part 1 — Surface Roughness Terminology Part 1: Surface and Its Parameters

3.3 *JIS Standards*[3]

JIS B0601 — Surface Roughness - Definitions and Designations

JIS Z2245 — Method of Rockwell and Rockwell Superficial Hardness Test

4 Terminology

4.1 *tape frame* — the frame which applies the wafer tape to the wafer and retains the wafer.

4.2 *wafer tape* — an adhesive plastic tape which retains the wafer or diced chip. It is used between the dicing process and the die-bonding process.

5 Ordering Information

5.1 Purchase orders for tape frames furnished to this specification shall include quantity.

6 Requirements

6.1 *Dimensions* — See Table 1 and Figure 1.

Table 1 300 mm Tape Frame Dimensions

Symbol	*Dimension (mm unless noted))*	*Note*
ϕ A	350 ± 0.5	Inner diameter
ϕ B	400 ± 0.5	Outer diameter
C	380 + 0/-0.5	Width between two cords
D	380 + 0/-0.5	Width between two cords
E	170.4	Outline dimension
F	172	Outline dimension
G	86	Outline dimension
H	90	Outline dimension
I	120°	
J	60°	Partition out with diameter *N* as standard
tK	1.5 or (1.2)	Plate thickness
L	190	
M	190	Frame warpage
ϕ N	3.2	Pin diameter
P	100 ± 0.2	Diameter *N* position
Q	18 ± 0.2	Diameter *N* position
R	276	1 Notch position
S	19.6 ± 0.2	1 Notch position

NOTE 1: Plate thickness of 1.5 mm is recommended.

NOTE 2: No burrings on the edges.

NOTE 3: Surface Roughness: $R_{max} \leq 1$ µm, $R_a \leq 0.1$ µm; (surface indicated as Δ) unindicated Cut Surface Roughness: $R_{max} \leq 100$ µm, $R_a \leq 25$ µm.

[1] *American National Standards Institute, 1430 Broadway, New York, NY 10018*

[2] *International Organization for Standardization, C.P. 56, CH-1211 Geneva 20, Switzerland*

[3] *Japanese Standards Association, 1-24, Akasaka 4 Chome, Minato-ku, Tokyo, Japan*

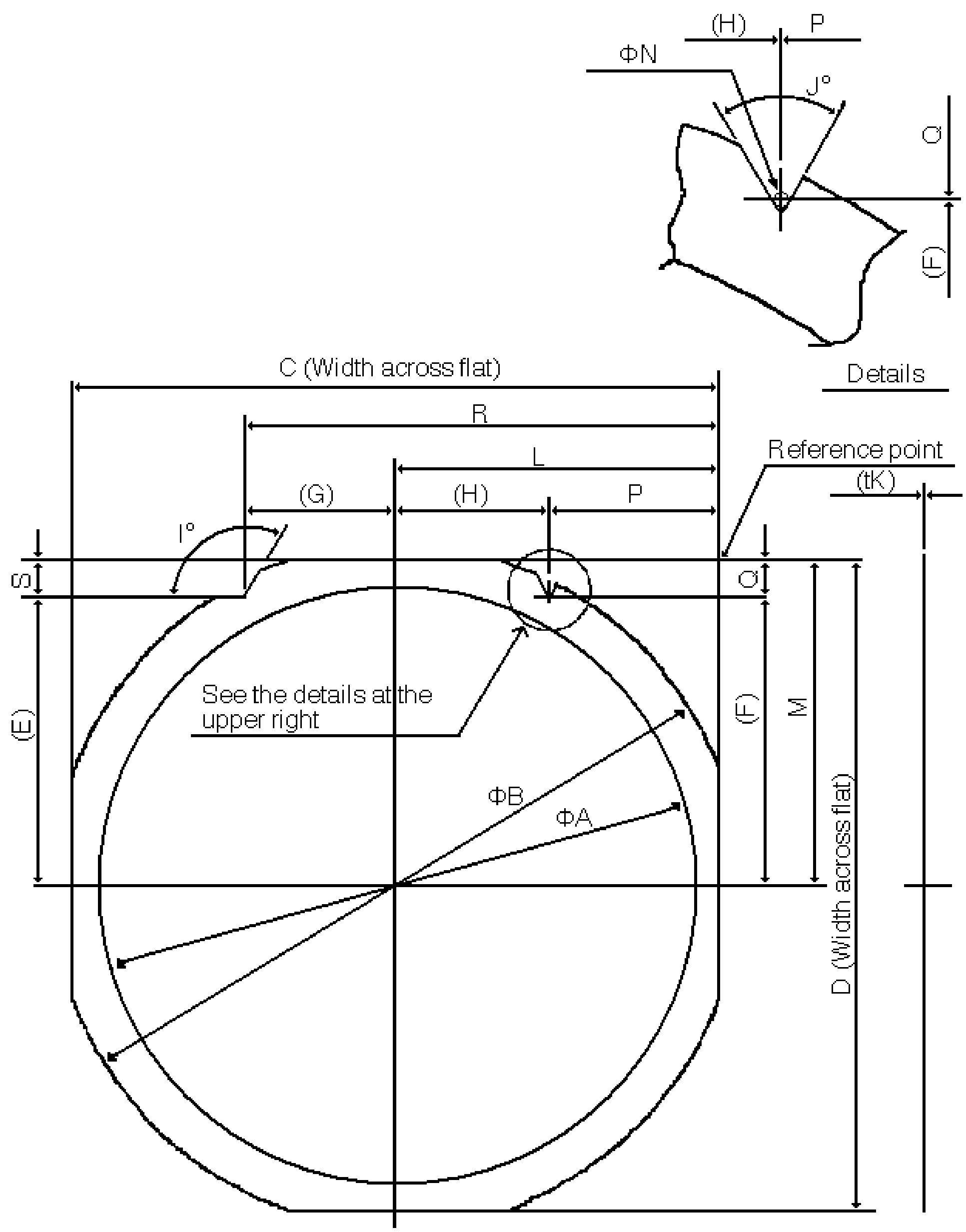

Figure 1

300 mm Tape Frame Dimensions

6.2 *Surface Hardness* — HRc ≥ 47

6.3 *Resiliency* — Must return to original shape, where the linear scale ruler reads 0, after one side is held firm and the other is bent with a force of 30 N for 60 seconds.

6.4 *Surface Roughness* — $R_a \leq 0.1$ µm, R_{max} is within ≤ 1.0 µm

6.5 *Flatness* — Within 0.3 mm

7 Test Methods

7.1 *Dimensions* — To be measured with a measuring device, such as a caliper, with a precision of 0.05 mm.

7.2 *Surface Hardness* — To be measured according to the method in JIS Z2245 with a Rockwell Hardness Tester.

7.3 *Resiliency* — Secure one side of the frame in a vice, and bend with a force of 30 *N* for 60 seconds. After that, release the frame and measure the change from the original shape with a linear scale ruler. The linear scale ruler should have a precision of at least 0.5 mm.

7.4 *Surface Roughness* — Measure with a surface roughness gauge. Surface roughness is measured perpendicular to the undulation and must be shown as roughness average (R_a) and maximum peak-to-valley roughness height (R_{max}). Refer to ISO4287 Part 1, JIS B0601, and ANSI/ASME B46.1.

7.5 *Flatness* — Place the frame on a surface with near-zero flatness. Measure the lowest point and the highest point on the frame with a height gauge, and record the difference in these values. Turn the frame over and repeat the process. The flatness will be the larger of the two values.

8 Certification

8.1 Upon request of the purchaser in the contract or order, a manufacturer's or supplier's certification that the material was manufactured and tested in accordance with this specification, together with a report of the test results, shall be furnished at the time of shipment.

9 Packing and Package Labeling

9.1 The product must be packaged appropriately to prevent deformities, moisture, and contamination, as well as damage during normal shipping.

9.2 The products must be clearly marked with the purchase number, quantity, gross weight, and supplier's name.

9.3 Special packaging and delivery requests will be decided between the supplier and the purchaser at time of purchase.

9.4 *Surface Hardness* — HRc ≥ 47

9.5 *Resiliency* — Must return to original shape, where the linear scale ruler reads 0, after one side is held firm and the other is bent with a force of 30 *N* for 60 seconds.

9.6 *Flatness* — Within 0.3 mm

APPENDIX 1
BARCODE LABEL POSITIONS FOR 300 MM TAPE FRAMES

NOTE: The material in this appendix is an official part of SEMI G74 and was approved by full letter ballot procedures on March 17, 1999.

A-1 Barcode Label Positions

A-1.1 The recommended position for the barcode label is position (A in Figure A1-1).

A-1.2 However, it is acceptable if the barcode labels are within the shaded area (see B in Figure A1-1).

A-2 Reasons to recommend position (A)

A-2.1 It is easier to detect whether there are any barcode labels or not, without pulling out the frames.

A-2.2 It is convenient to have the labels on the opposite side of the notches, as the frames are normally pulled out from the notch side.

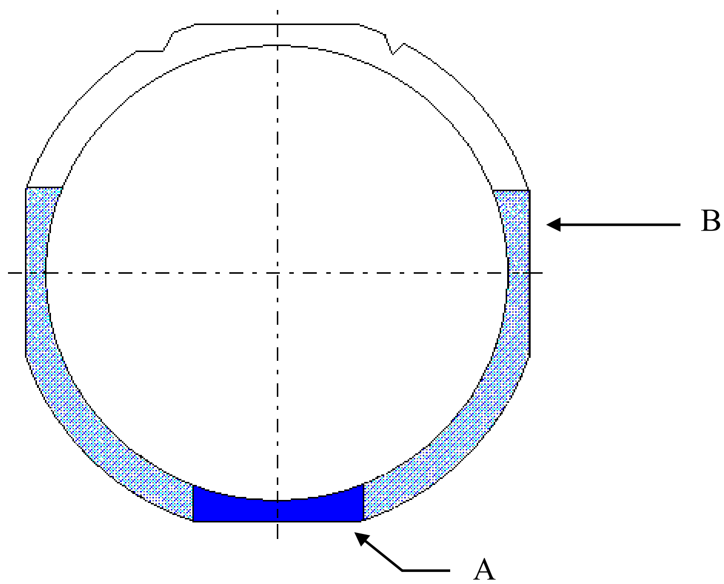

Figure A1-1

Barcode Label Positions

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI G75-0698
STANDARD TEST METHOD OF THE PROPERTIES OF LEADFRAME TAPE

1 Purpose

1.1 This standard describes procedures for measuring the mechanical, physical, chemical, thermal, and electrical properties of leadframe tape.

1.2 Equipment, sampling, and procedures are referred to in the individual test methods.

1.3 The test methods for the individual properties have been given in this standard.

1.3.1 Ionic impurities (see SEMI G75.1).

1.3.2 Adhesive strength (see SEMI G75.2).

1.3.3 Peel strength of protective film from leadframe tape (see SEMI G75.3).

1.3.4 Water absorption (see SEMI G75.4).

1.3.5 Weight loss (see SEMI G75.5).

1.3.6 Shrinkage factor (see SEMI G75.6).

1.3.7 Thermal decomposition temperature (see SEMI G75.7).

1.3.8 Coefficient of thermal expansion and glass transition temperature (see SEMI G75.8).

1.3.9 Tensile strength, elongation, and tensile modulus (see SEMI G75.9).

1.3.10 Volume and surface resistivity (see SEMI G75.10).

1.3.11 Dielectric constant and dissipation factor (see SEMI G75.11).

1.3.12 Breakdown strength (see SEMI G75.12).

1.3.13 Leakage current (see SEMI G75.13).

2 Scope

2.1 The methods help tape manufacturers, leadframe manufacturers, and their customers in evaluating leadframe tapes.

2.2 *Units*

2.2.1 This standard test method uses SI (metric) units.

3 Referenced Documents

3.1 Referenced documents are listed in each test method.

4 Terminology

4.1 *breakdown strength* — Under the specified test conditions, the quotient of the minimum r.m.s. voltage at the breakdown of the test piece (breakdown voltage) divided by the distance between the two electrodes (thickness of test piece).

4.2 *dielectric constant* — The amount of electrostatic energy stored in a unit volume of a substance in a unit electric field. It is called dielectric constant (εr) and expressed as the quotient of electrostatic capacity of a parallel condenser employing the test piece as the dielectric (C_x) divided by that of the same condenser when air (under the standard condition, the dielectric constant of air can be taken for that of vacuum) is used as the dielectric (C_o), measured under a specified frequency.

$$\text{i.e., } \varepsilon = C_x/C_o$$

4.3 *dielectric dissipation factor* — Dielectric dissipation factor is the tangent of the complementary angle of dielectric phase angle (tand). The dielectric phase angle is the phase difference angle (q) between sine-wave voltage applied to the test piece and the current component having the same frequency as the applied voltage caused by the voltage application.

4.4 *HAST* — Highly accelerated stress test: For example, 121° C/2 atm/100% RH.

4.5 *leadframe tape* — An adhesive coated tape. After removing protective film, laminated to the inner leads, which stops lead shift and/or lead lift during the assembly process.

4.6 *protective film* —A plastic film to cover the adhesive on leadframe tapes. This film prevents the adhesive from becoming contaminated and is removed from the leadframe tape just prior to taping the lead-frame.

4.7 *strain* — The ratio of elongation of the sample length to the original length at the applied stress level.

4.8 *stress* — The applied force per unit cross-sectional area of the sample.

4.9 *surface resistivity* — The quotient of the voltage gradient parallel to the current along the surface of the test piece divided by the current per unit width of the surface.

4.10 *tensile break strength* — The tensile force per unit of original cross section of the sample at the point of breakage.

4.11 *tensile modulus* — The ratio of stress to strain of the sample below the yield point, in the elastic region of the stress/strain curve.

NOTE: Plastic materials may not have a true elastic region in the stress/strain curve or force/elongation curve. A tangent is drawn to the maximum slope of the curve in order to determine the modulus.

4.12 *thermal decomposition temperature (base film and adhesive)* — The thermal decomposition temperature is determined at 5% of the weight loss when the tape is set to the thermal ramp at 10° C/minute.

4.13 *volume resistivity* — The quotient of the voltage gradient parallel to the current within the test piece divided by the current density.

5 Significance

5.1 *Ionic Impurities*

5.1.1 Ionic contamination can adversely affect the reliability of semiconductor devices by causing leakage currents and aluminum corrosion.

5.2 *Adhesive Strength*

5.2.1 Low adhesive strength may result in inner leads movement of leadframe during the assembly and packaging process which may result in low yield or poor device reliability.

5.3 *Peel Strength of Protective Film from Leadframe Tape*

5.3.1 If the peeling strength of protective film from leadframe tape varies in peeling strength, the taping machines will not operate consistently.

5.4 *Water Absorption*

5.4.1 If the leadframe tapes absorb an excessive amount of water in storage, before or after packaging, then reliability of devices made by these leadframes may be affected. Current leakage and corrosion of device metallization may occur.

5.5 *Weight Loss*

5.5.1 Weight loss may indicate that devices manufactured with the leadframe tape may have reliability problems due to the tape outgassing.

5.6 *Shrinkage Factor*

5.6.1 Excessive shrinkage at thermal processing may cause the lead shift and wire bond problems for automatic bonders.

5.7 *Thermal Decomposition Temperature*

5.7.1 The devices manufactured with leadframe tape that decomposes at too low a temperature may have lower reliability.

5.8 *Coefficient of Thermal Expansion and Glass Transition Temperature*

5.8.1 Excessive expansion of the leadframe tape may cause lead shift and/or lead lift and result in dislocated bonds from automatic bonders.

5.9 *Tensile Strength, Elongation, and Tensile Modulus*

5.9.1 If the tensile strength, elongation, and tensile modulus varies, the taping machines will not operate consistently.

5.10 *Volume and Surface Resistivity*

5.10.1 Low volume and/or surface resistivity is indicative of potential leakage currents between leadframe inner leads which can affect the function of the device.

5.11 *Dielectric Constant and Dissipation Factor*

5.11.1 High dielectric constant materials used in semiconductor packages may cause transmission delays. High dielectric loss causes energy loss, which leads to exothermic problems in semiconductor packages.

5.12 *Breakdown Strength*

5.12.1 Very low breakdown strength may cause devices to fail in use.

5.13 *Leakage Current*

5.13.1 A high leakage current between leadframe inner leads, which may be exacerbated due to high moisture test conditions and impurities in the tape, may result in poor device reliability.

6 Procedure

6.1 Procedures are detailed in the Test Methods following this document.

7 Reporting Results

7.1 The sample size per lot and the reported items shall be determined by agreement between user and supplier.

7.2 The report shall contain the following information:

7.2.1 *Leadframe Tape Material* — Manufacturer, type, and lot number.

7.2.2 Notification of acceptance or rejection.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user' attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI G75.1-0698
TEST METHOD FOR MEASUREMENT OF IONIC IMPURITIES IN LEADFRAME TAPE

1 Summary of Method

1.1 Ionic impurities are extracted from sample tape by water at 100°C or 121°C and quantitatively analyzed by ion chromatography and flame photometry or atomic absorption spectrometry. The pH and electrical conductivity of the extracted solutions are also measured.

1.2 If sample tape needs the cure before the extraction, vender should inform the customer of the necessity of curing and report the impurity data after cure.

1.3 Ion chromatography is used to determine the presence and concentration of the following ionic species: Na^+, $NH4^+$, K^+, NO_3^-, Cl^-, Br^-, SO_4^{2-}, PO_4^{3-}.

1.4 Flame photometry or atomic absorption spectrometry is used to determine the concentration of Na^+ and K^+ ions.

1.5 pH and conductivity measurements are also described.

2.1 *SEMI Standards*

SEMI G29 — Test Method for Trace Contaminants in Molding Compounds

SEMI G59 — Test Method for Measurement of Ionic Contamination on Leadframe Interleafing and the Contamination Transferred from the Interleafing to the Leadframes

2.2 *ASTM Standards*[1]

ASTM D 1125 — Standard Test Methods for Electrical Conductivity and Resistivity of Water

ASTM D 1193 — Standard Specification for Reagent Water

ASTM D 4327 — Standard Test Method for Anions in Water by Ion Chromatography

ASTM E 70 — Standard Test Method for pH of Aqueous Solutions with the Glass Electrode

2.3 *JIS Specifications*[2]

JIS K 0121 — General Rules for Atomic Absorption Spectrochemical Analyses

JIS Z 8802 — Method for Determination of pH of Aqueous Solutions

3 Interferences

3.1 All the sample preparations and measurements must be carried out in clean containers which have been washed in deionized water in order to reduce any spurious readings.

3.2 Electrodes and syringes must be similarly cleaned before each test.

3.3 Contamination from the sampling process may also affect the results.

4 Equipment

4.1 Ion Extraction Vessels-Parr bomb with Teflon liner.

4.2 Ion chromatograph for anion and cation analysis (see SEMI G59).

4.3 Flame photometer or atomic absorption spectrometer.

4.4 Standard solution preparation vessels, balance and volumetric dispensers (see SEMI G29 and SEMI G59).

4.5 pH meter.

4.6 Microconductivity cell and meter.

5 Reagents and Materials

5.1 Deionized water, conductivity of less than 1.0 µ S/cm at 25°C per ASTM D 1193.

5.2 Eluents and regenerants for specific chromatograph columns prepared per chromatograph equipment manufacturer's recommendations so that the water peak can be separated from the ionic peaks.

5.3 *Compounds for Standard Solutions*

5.3.1 *Cations* — NaCl, NH_4Cl, KCl

5.3.2 *Anions* — NaCl, $Na2HPO_4 \bullet 12H2O$, NaBr, $NaNO_3$, K_2SO_4

NOTE: All compounds to be reagent grade.

1 American Society for Testing Materials, 100 Barr Harbor Drive, West Conshohocken, PA 19428-2959

2 Japanese Standards Association, 1-24, Akasaka 4 Chome, Minato-ku, Tokyo, Japan

5.4 pH standard solutions.

6 Sampling

6.1 Personnel handling the tape must wear double-layered cotton gloves and polyethylene outer gloves in order to avoid additional sample contamination.

6.2 The sampling is one sample per one lot. The vendor must report the definition of lot, if customer requires it.

7 Preparation of Standard Solution and Equipment Calibration

7.1 *Preparation of Standard Solutions and Chromatograph Calibration*

7.1.1 Refer to SEMI G59, Section 9 and ASTM D 4327.

7.2 *Preparation of Standard Solutions and Flame Photometer or Atomic Absorption Spectrometer Calibration*

7.2.1 Refer to SEMI G29 and JIS K 0121.

7.3 *Preparation of Standard Solutions and pH Meter Calibration*

7.3.1 Refer to ASTM E 70 or JIS Z 8802.

7.3.2 Using the standard pH solutions, calibrate the pH meter according to the manufacturer's instructions.

7.4 *Preparation of Standard Solutions and Conductivity Cell Calibration*

7.4.1 Refer to ASTM D 1125.

8 Measurement

8.1 *Procedure for Impurity Extraction*

8.1.1 Remove the protective film from the sample of tape. Cure the tape per tape manufacturer's recommendation, if necessary.

8.1.2 Cut the sample of tape so that it becomes smaller than 2 cm × 2 cm.

8.1.3 Place 5.0 ± 0.1 grams of the tape sample into the Parr bomb, and add 50 ± 0.5 grams of deionized water.

8.1.3.1 In a second bomb, add deionized water only so that a blank solution may be obtained for measurement of the ionic contributed by the bomb.

NOTE: It may be necessary to perform the blank test on both bombs in order to leach out excessive extractable ionic species.

8.1.4 Seal the caps and heat the bombs in an oven set at 100°C ± 2°C, for 20 ± 0.25 hours.

NOTE: The oven temperature may be set at 121°C ± 2°C for 20 hours, if specified.

8.1.5 Allow the bombs to reach room temperature.

8.1.6 Open the bombs just before the measurements are to be made. Measurements must be made within eight (8) hours of the completion of the sample preparation.

8.2 *Quantitative Analysis by Ion Chromatography*

8.2.1 Prepare the chromatograph for operation by regenerating the columns according to the manufacturer's recommendations.

8.2.2 Run the eluent through the chromatograph until a stable baseline calibration is established.

8.2.3 Inject the recommended sample size of test solution into the chromatograph and record the ion chromatogram.

8.2.4 Repeat for all the samples and also run the background sample.

8.2.5 Determine the ionic type and concentration from the calibration curves.

8.2.6 Results

8.2.6.1 The concentration of ionic species in the leadframe tape is given by:

$$A = \frac{(B - C) \times 50}{5}$$

where :

A is the ionic content of the leadframe tape (ppm)

B is the ionic content on the extracted solution, determined from the calibration curves (ppm)

C is the ionic concentration of the back-ground sample (ppm)

8.3 *Quantitative Analysis by Flame Photometer or Atomic Absorption Spectrometer*

8.3.1 Set a specific operational condition for an apparatus.

8.3.2 Introduce the recommended sample size of test solution into a flame.

8.3.3 Repeat for all the samples and also introduce the background sample.

8.3.4 Determine the concentration from calibration curves.

8.3.5 *Results*

8.3.5.1 The concentration of ionic species in the leadframe tape is given by:

$$A = \frac{(B - C) \times 50}{5}$$

where :

A is the ionic content of the leadframe tape (ppm)

B is the ionic content on the extracted solution, determined from the calibration curves (ppm)

C is the ionic concentration of the back-ground sample (ppm)

8.4 *pH Measurements*

8.4.1 Place the pH electrode into the sample solution and record the pH after one (1) minute.

8.5 *Electrical Conductivity Measurements*

8.5.1 Place the conductivity cell into the sample solution and record the conductivity after one (1) minute.

SEMI G75.2-0698
TEST METHOD FOR MEASUREMENT OF ADHESIVE STRENGTH OF LEADFRAME TAPE

1 Summary of Method

1.1 Two methods are described:

1.1.1 *Pull-Up Method* — Using a hook attached to a tensile tester, the tape is pulled away from the leadframe inner leads.

1.1.2 *Push-Down Method* — Using a probe attached to a tensile tester, a leadframe inner lead is pushed away from the tape.

1.2 The adhesive strength between the lead and the tape should be measured at 23°C ± 5°C and 250°C.

2 Equipment

2.1 Tensile tester with appropriate load cell, clamping chucks, and a chart recorder. Tensile tester shall keep constant the traveling speed of clamping chucks, of which the traveling distance can be read to the nearest 1 mm, and shall simultaneously record the load imposed on the sample. It shall measure and record the imposed load with ± 1% on a chart recorder.

2.2 *Pull-Up Method*

2.2.1 A clamp should be suitable for each leadframe type. Example of the clamp design, for a typical 40 pins DIP leadframe, is shown in Figure 1.

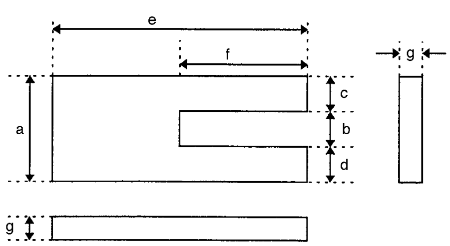

Figure 1
Example of Clamp Design
(40 Pins DIP Leadframe)

Table 1 Dimension and Material of Clamp and Hook in Push-Up Method

Item/Dimension	*Value*	*Material*	*Reference Figure*
Clamp		Aluminum	1
a	60 mm		
b	8 mm		
c	26 mm		
d	26 mm		
e	60 mm		
f	30 mm		
g	3 mm		
Pull-Up Hook		Piano Wire	2
ϕ	0.4 mm		
a	100 mm		
b	5 mm		
r	2.0 mm		

2.2.2 A pull-up hook should be suitable for each leadframe type. Example of the pull-up hook, for a typical 40 pins DIP leadframe, is shown in Figure 2.

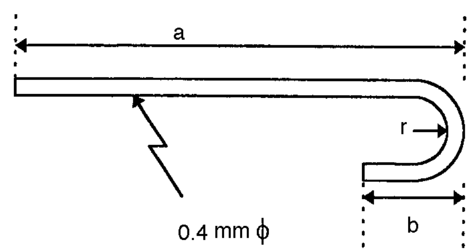

Figure 2
Pull-Up Hook
(40 Pins DIP Leadframe)

2.3 *Push-Down Method*

2.3.1 A table should be suitable for each leadframe type. Example of the table, for a typical 40 pins DIP leadframe, is shown in Figure 3.

2.3.2 A push-down probe should be suitable for each leadframe. Example of the push-down probe, for a typical 40 pins DIP leadframe, is shown in Figure 4.

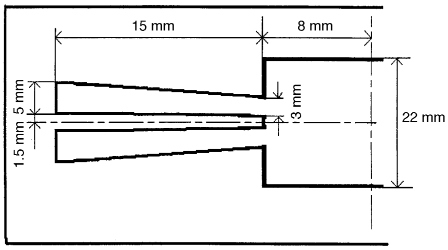

Figure 3
The Dimension of the Table

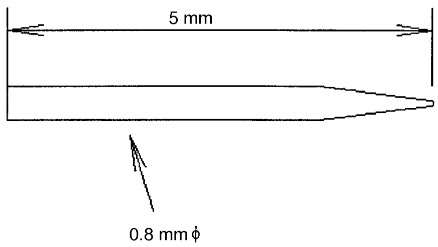

Figure 4
Example of Push-Down Probe
(40 Pin DIP Leadframe)

3 Test Condition

3.1 Adhesion testing shall be carried out at the following ambient conditions:

Temperature — 23°C ± 5°C

Humidity — 50 ± 5% RH

4 Sampling

4.1 The sampling is one sample per one lot. The vendor must report the definition of lot, if the customer requires it.

5 Preparation of Specimens

5.1 *Leadframe Manufacturers*

5.1.1 Leadframes shall be taped using conditions for temperature, pressure, and dwell-time agreed upon between vendor and customer.

NOTE: A typical taped 40 pins DIP leadframe is shown in Figure 5, and relevant information for this frame is shown in Table 2.

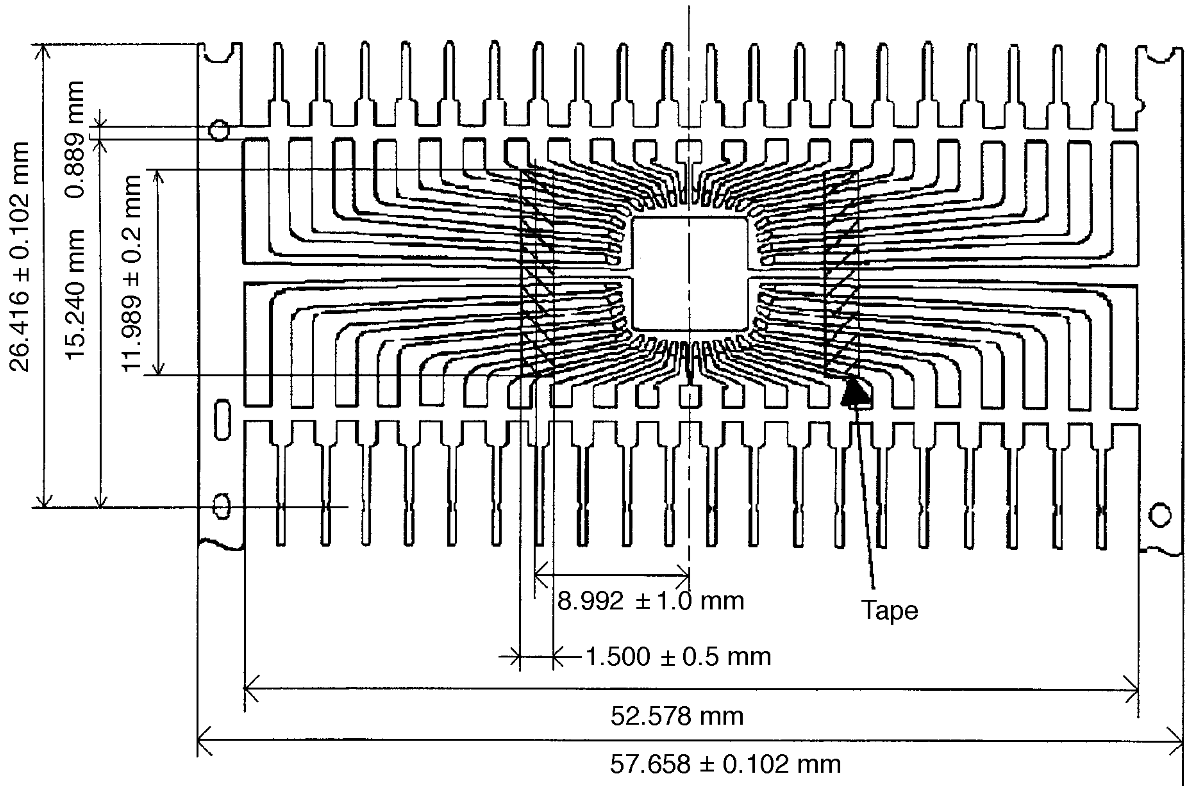

Figure 5
Typical Taped 40 Pin DIP Leadframe

Table 2 Relevant Information for 40 Pin DIP Leadframe

Leadframe Attribute	*Specification*
Leadframe thickness	0.25 mm
Leadframe material	Alloy 42
Leadframe manufacturing process	Stamping
Plating	None/Silver/Others
Surface treatment	To be agreed upon between vendor and customer.

NOTE: The surface state of Alloy 42 is stable compared with Cu alloy which is oxidized easily.

6 Procedure

Hot adhesive strength at 250°C should be measured on the heater block with 60 ± 10 seconds.

6.1 *Pull-Up Procedure*

6.1.1 Set the tensile tester in the up-mode, and adjust the rate to 100 mm/minute.

6.1.2 Place the leadframe under the clamp as shown in Figure 6.

6.1.3 Position the hook under the tape between the tie bar and its neighboring inner lead as shown in Figure 6. Similar leads and hook position shall be selected for other types of leadframes.

6.1.4 Adjust the hook position until it just touches the tape and initiate the tensile tester in the up-mode. Record the strength to break the adhesion between the lead and the tape.

6.1.5 Repeat the test for each leadframe in the samples.

6.1.6 Calculation

6.1.6.1 Discard the maximum and minimum values recorded, and average the remainder.

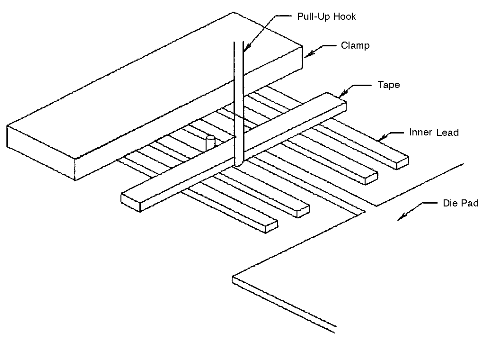

Figure 6
Measurement of Pull-Up Strength

6.2 *Push-Down Procedure*

6.2.1 Set the tensile tester in the down-mode, and adjust the rate to 100 mm/minute.

6.2.2 Place the leadframe on the table as shown in Figures 7 and 8.

6.2.3 Position the probe at Point A over the selected inner lead as shown in Figure 9.

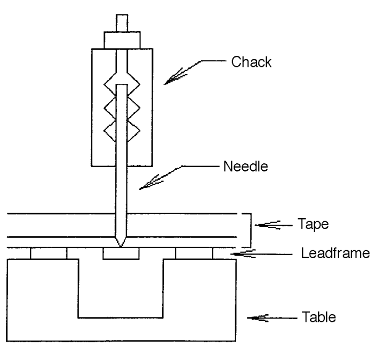

Figure 7
Measurement of Push-Down Strength
(Cross-Section)

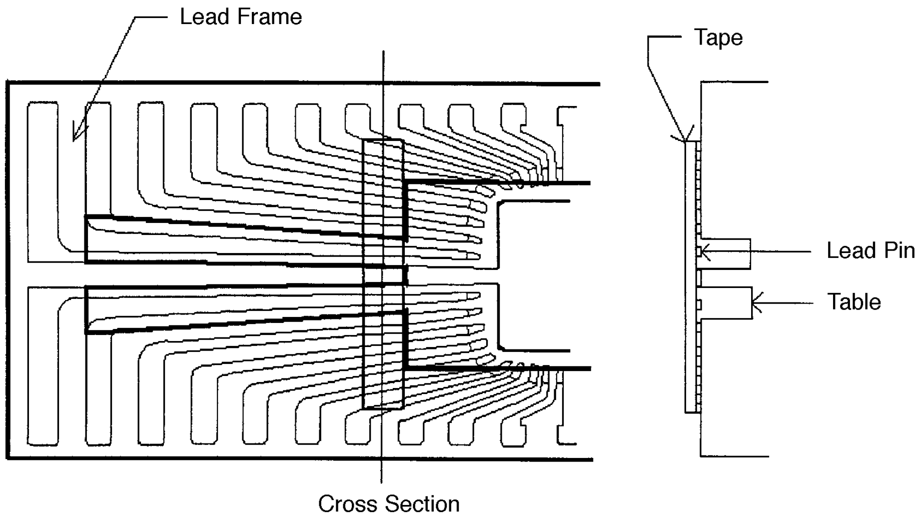

Figure 8
Relation of Leadframe and Table in Push-Down Method

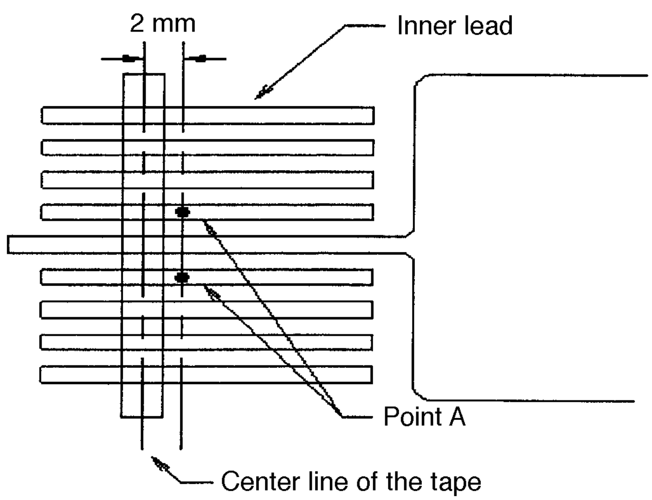

Figure 9
Probe Position over the Selected Inner Lead in Push-Down Method

6.2.4 Adjust the probe position until it just touches the inner lead and initiate the tensile tester in the down-mode. Record the strength to break the adhesion between the inner lead and the tape.

6.2.5 Repeat the test for each of the test positions noted in Section 6.2.4.

6.2.6 Repeat the tests for each leadframe in the sample.

6.3 *Calculation*

6.3.1 Discard the maximum and minimum values recorded and average the remainder.

TEST METHOD FOR MEASUREMENT OF THE PEEL STRENGTH OF PROTECTIVE FILM ON LEADFRAME TAPE

1 Summary of Method

1.1 A tensile tester is used to peel the film away from the adhesive (see Figure 1) and directly measure the peel strength with a calibrated load cell.

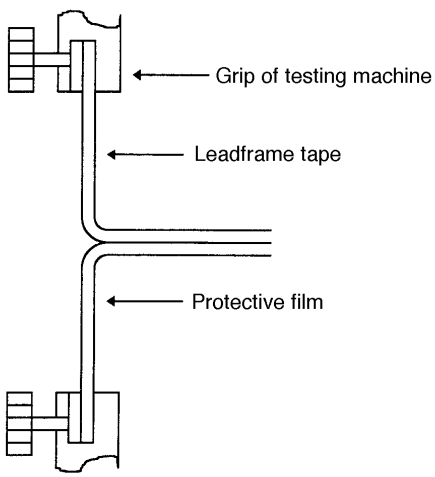

Figure 1
Attaching of Test Piece for T-Type Peel Test

2 Equipment

2.1 Tensile tester with appropriate load cell, clamping chucks, and a chart recorder.

2.1.1 Tensile tester shall keep constant the traveling speed of clamping chucks, of which the traveling distance can be read to the nearest 1 mm, and shall simultaneously record the load imposed on the sample. It shall measure and record the imposed load with ± 1% on a chart recorder.

3 Test Condition

3.1 Peel strength testing shall be carried out at the following ambient conditions:

Temperature — 23 ± 5°C

Humidity — 50 ± 5% RH

4 Sampling

4.1 The sampling is one sample per one lot. The vendor must report the definition of lot, if the customer requires it.

4.2 The width of the tape tested shall be 15 ± 0.2 mm.

5 Equipment Calibration and Setup

5.1 Refer to the tensile tester manufacturer's equipment manual for setup and calibration.

5.2 The sample shall be attached and peeled for T-type peel test shown in Figure 1.

5.3 Both ends of a test piece shall be attached to the grips of the testing machine specified in Section 2.1.

5.4 The pulling rate shall be set to 300 mm/minute.

5.5 The pulling distance shall be 125 mm minimum from the start of peeling.

5.6 The peel strength shall be recorded in grams.

6 Measurements

6.1 As shown in Figure 2, draw the optimum straight line which is parallel to the abscissa for peeling length, that passes through the peeling curve, and find the peeling load after eliminating initial 25 mm of peeling length.

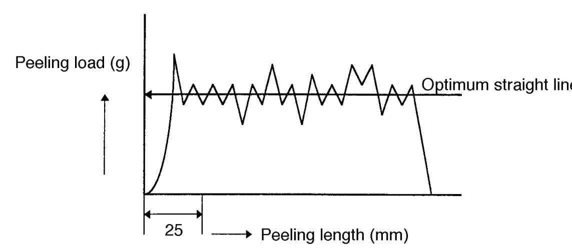

Figure 2
Obtaining Peeling Load by the Optimum Straight Line Method

SEMI G75.4-0698
TEST METHOD FOR MEASUREMENT OF WATER ABSORPTION OF LEADFRAME TAPE

1 Summary of Method

1.1 Leadframe tape is exposed to an environment at constant humidity and temperature. The water absorption is measured by directly weighing the samples before and after test.

2 Referenced Documents

NOTE: As listed or revised, all documents cited shall be the latest publications of adopted standards.

2.1 *ASTM Specification*[1]

ASTM D 1193 — Standard Specification for Reagent Water

3 Equipment

3.1 Direct reading electric balance capable of reading 0.1 mg.

3.2 Thermohygrostat capable of 23 ± 2°C and 50 ± 5% RH.

3.3 Thermohygrostat capable of 85 ± 2°C and 85 ± 5% RH.

4 Materials

4.1 *Deionized Water* — Refer to ASTM D 1193.

5 Test Conditions

5.1 *Specimen Conditioning*

Temperature — 23 ± 2°C

Humidity — 50 ± 5% RH

5.2 *Test Conditions*

Temperature — 85 ± 2°C

Humidity — 85 ± 5% RH

6 Sampling

6.1 The sampling is one sample per one lot. The vendor must report the definition of lot, if customer requires it.

6.2 The sample's weight shall be 1 gram minimum.

6.3 Use plastic tweezers to handle the samples.

1 American Society of Testing and Materials, 100 Barr Harbor Drive, West Conshohoken, PA 19428-2959 (all cited standards may be found in Volume 10.05 of the Annual Book of ASTM Standards)

7 Equipment Setup and Calibration

7.1 Refer to the thermohygrostat manufacturer's manual for setup and calibration procedures.

8 Procedure

8.1 Separate off the protective film from the leadframe tape.

8.2 Set the thermohygrostat at 23°C and 50% RH and condition the samples at these conditions for 16 hours minimum.

8.3 Weigh each sample to 0.1 mg accuracy (W_1, Units-grams).

8.4 Set the thermohygrostat at 85°C and 85% RH and leave the samples at these conditions for 20 ± 0.25 hours.

8.5 Wipe the water from sample surface with lint-free clean wipes.

8.6 Reweigh each sample (W_2, Unit-grams).

8.7 *Calculation*

The water absorption obtained, A (%), is deter-mined from the following equation:

$$A(\%) = \frac{(W_2 - W_1) \times 100}{W_1}$$

SEMI G75.5-0698
TEST METHOD FOR MEASUREMENT OF WEIGHT LOSS OF LEADFRAME TAPE

1 Summary of Method

1.1 Specimens are weighed before and after exposure to temperatures comparable to those used in the assembly and packaging of microelectronics devices. The weight loss is calculated as a percentage change in the weight of the sample.

2 Equipment

2.1 Direct reading balance calibrated to 0.1 mg accuracy.

2.2 Recirculating air oven capable of 300°C ± 2°C accuracy.

3 Sampling

3.1 The sampling is one sample per one lot. The vendor must report the definition of lot, if customer requires it.

4 Preparation of Specimens

4.1 Allow the samples to stabilize at 23°C ± 2°C and 50 ± 5% RH for 16 hours minimum. This may be carried out in a climate controlled room or in a thermohygrostat.

4.2 Cut specimens out of the samples such that the minimum weight of each specimen is 1 gram.

5 Test Conditions

5.1 *Test Condition 1* — 100°C for 60 ± 1 minute.

5.2 *Test Condition 2* — 200°C for 60 ± 1 minute.

5.3 *Test Condition 3* — 300°C for 10 ± 0.5 minutes.

NOTE: Alternate temperature may be used by agreement between vendor and customer.

6 Equipment Setup and Calibration

6.1 Refer to the thermohygrostat manufacturer's manual for setup and calibration procedures.

7 Procedure

7.1 In order to ease the handling of the specimens, place each into a weighed cup or tray which has tared their weight (W_1).

7.2 Place the specimens in the oven at the specified test conditions.

7.3 Remove the specimens from the oven and store at 23°C ± 2°C and 50 ± 5% RH for 16 hours minimum.

7.4 Reweigh the specimens (W_2).

7.5 *Calculation*

7.5.1 The Weight Loss, A (%), is determined from the following equation:

$$A(\%) = \frac{(W_1 - W_2) \times 100}{W_1}$$

SEMI G75.6-0698
TEST METHOD FOR MEASUREMENT OF THE SHRINKAGE FACTOR OF LEADFRAME TAPE

1 Summary of Method

1.1 The length of tape samples is measured before and after exposure to temperatures comparable to those used in the assembly and packaging of IC. The shrinkage is calculated as a percentage in the dimension measured.

2 Equipment

2.1 Magnifying projector with 0.01 mm accuracy

2.2 Circulating air oven capable of 300 ± 2°C accuracy

2.3 Cutting die for sample preparation

2.4 Thermohygrostat

2.5 Straight edge

2.6 Scribing tool

3 Sampling

3.1 The sampling is one sample per one lot. The vendor must report the definition of lot, if the customer requires it.

4 Preparation of Specimens

4.1 Cut specimens out of the samples using the cutting die. The specimen shall be 100 ± 1.0 mm long and 10 ± 1.0 mm wide.

4.2 Allow the specimen to be stabilized at 23° ± 2°C and 50 ± 5% RH for 16 hours minimum. This may be carried out in a climate controlled room or in a thermohygrostat.

4.3 Using the straight edge and scribing tool, scribe marks on the specimens as shown in Figure 1. The marks shall be parallel to each edge of the specimen, and the distance to be measured, L, shall be parallel to the long side of the specimen. The mark shall be located within 5 mm of the ends of the specimen.

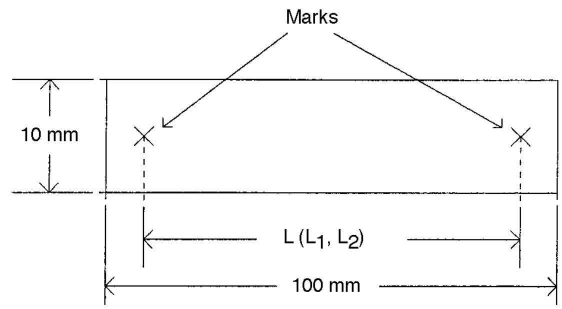

Figure 1
Size of a Marked Specimen

5 Test Conditions

5.1 *Baking Condition 1* — 100°C for 60 ± 1 minute.

5.2 *Baking Condition 2* — 200°C for 60 ± 1 minute.

5.3 *Baking Condition 3* — 300°C for 10 ± 0.5 minutes.

NOTE: Alternate temperatures may be used by agreement between vendor and customer.

6 Procedure

6.1 Place a specimen between the glass plates of the magnifying projector and measure the length, L_1, between two marks (see Figure 1). Repeat this measurement for all specimens.

6.2 Place the specimen in the oven at the appropriate test condition.

6.3 Remove the specimens from the oven and store at 23° ± 2°C and 50 ± 5% RH for 16 hours minimum.

6.4 Place the specimens between the glass plates of the magnifying projector and measure the new length, L_2, between two marks used in Section 6.1.

6.5 *Calculation*

6.5.1 The shrinkage factor, A (%), is determined from the following equation:

$$A(\%) = \frac{(L_1 - L_2) \times 100}{L_1}$$

where :

L_1 is the length (mm) of the specimen before baking

L_2 is the length (mm) of the specimen after baking

SEMI G75.7-0698
TEST METHOD FOR MEASUREMENT OF THERMAL DECOMPOSITION TEMPERATURE OF LEADFRAME TAPE AND ADHESIVE

1 Summary of Method

1.1 A thermogravimetric (TG) analyzer is used to monitor the weight of a tape sample as the temperature increases to 700°C. It should be made to measure the leadframe tape or the base film and the adhesive separately. The results are obtained as a plot of Weight Retention versus Temperature, from which the thermal decomposition temperature for both the base film and the adhesive may be obtained.

2 Equipment

2.1 Thermogravimetric (TG) analyzer capable of 0.01 mg accuracy.

2.2 Thermohygrostat

3 Sampling

3.1 The sampling is one sample per one lot. The vendor must report the definition of lot, if customer requires it.

4 Preparation of Specimens

4.1 Allow the samples to be stabilized at 23 ± 5°C and 50 ± 5% RH for 16 hours minimum. This may be carried out in a climate controlled room or in a thermohygrostat.

4.2 Cut specimens from the sample. The specimen shall weigh 10 to 20 mg.

NOTE 1: The base film before coating with the adhesive can be used for the test. The vendor has to ship the base film before coating with the adhesive, if customer requires it.

NOTE 2: The adhesive sample can be obtained by scraping the adhesive.

5 Equipment Setup and Calibration

5.1 Refer to Thermogravimetric Analyzer manufacturer's manual for setup and calibration procedures.

5.2 The ambient in the measurement shall be air.

6 Procedure

The measurement of TG should be made to measure the leadframe tape or the base film and the adhesive separately.

6.1 Place the specimen in the platinum vessel.

6.2 Set the thermal ramp to 10 ± 1°C/minute and maximum temperature to 700°C.

6.3 Repeat for all specimens.

7 Method of Reading TG Curve

7.1 In Figure 1, the thermal decomposition is determined by the temperature at 5% of the weight loss.

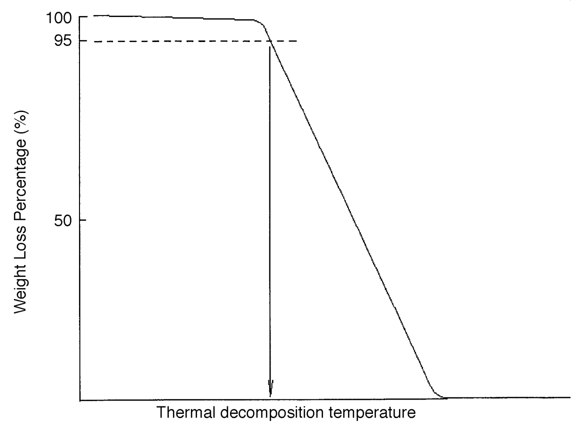

Figure 1
TG Curve of the Leadframe Tape

TEST METHOD FOR MEASUREMENT OF THE COEFFICIENT OF THERMAL EXPANSION AND GLASS TRANSITION TEMPERATURE OF LEADFRAME TAPE

1 Summary of Method

1.1 A thermal mechanical analyzer is used to monitor the dimension of a tape sample with temperature increases to 400°C. It can be made to measure the base film, adhesive, and the leadframe tape. The results are obtained as a plot of expansion versus temperature, from which Coefficient of Thermal Expansion (CTE) and Glass Transition Temperature (Tg) may be obtained. CTE above the Tg cannot be measured because of softening and elongation of the sample.

2 Equipment

2.1 Thermal mechanical analyzer (TMA) with chart recorder.

2.2 Thermohygrostat

2.3 Cutting die for sample preparation

2.4 *Calipers* — 0.1 mm accuracy

3 Sampling

3.1 The sampling is one sample per one lot. The vendor must report the definition of lot, if customer requires it.

4 Preparation of Specimens

4.1 Cut specimens out of the samples using the cutting die. The specimens shall be 20 ± 0.1 mm long and 5.0 ± 0.1 mm wide.

4.2 Allow the samples to be stabilized at 23 ± 5°C and 50 ± 5% RH for 16 hours minimum. This may be carried out in a climate controlled room or in a thermohygrostat.

5 Equipment Setup and Calibration

5.1 Refer to the thermal mechanical analyzer manufacturer's manual for setup and calibration procedures.

Procedure

6.1 Set the specimen to the chuck so that the length of the specimen under test is 10 ± 0.1 mm. Measure the specimen length using calipers.

6.2 Attach the chuck to the TMA.

6.3 Zero the recorder.

6.4 Set the Thermal Ramp to 10°C/minute, the maximum temperature to 400°C, and the load to 2.0 ± 0.2 grams.

6.5 Initiate the test sequence and obtain a chart record of Elongation of the specimen versus Temperature (see Figure 1).

6.6 Repeat for all specimens.

6.7 Calculation of Results

6.7.1 Coefficient of Thermal Expansion (k) — Calculate the CTE using the following equation:

$$k = \frac{\Delta L}{L \times \Delta T}$$

where :

L is the length (mm) of the specimen at room temperature.
ΔL is the elongation of the specimen (mm) for a given temperature difference, Δ T (°C).
These values are taken from the chart as shown in Figure 1.

6.7.2 Glass Transition Temperature (Tg)

6.7.2.1 On the chart, draw a best-fit tangent line to the curve between Point (A) and (B) and a second tangent between Point (C) and (D) (see Figure 1).

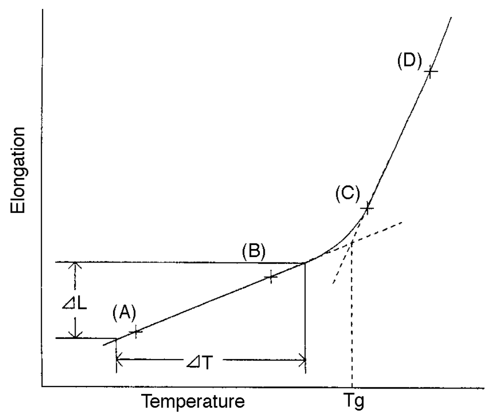

Figure 1
Coefficient of Thermal Expansion (CTE)

6.7.2.2 Extend the lower tangent line above its highest temperature and the higher tangent line below its lowest temperature until they intersect. The temperature at the intersection point is the Glass Transition Temperature.

SEMI G75.9-0698
TEST METHOD FOR MEASUREMENT OF TENSILE STRENGTH, ELONGATION, AND TENSILE MODULUS OF LEADFRAME TAPE

1 Purpose

1.1 Tensile strength, elongation, and tensile modulus of leadframe tape are measured by a tensile pull tester, which is used to stretch the tape samples to the point of breakage with a calibrated load cell.

2 Equipment

2.1 Tensile pull tester with 100 kg MAX load cell, sample clamping chucks, and a chart recorder.

2.2 Micrometer with 0.001 mm accuracy.

2.3 Calipers with 0.02 mm accuracy.

3 Test Condition

3.1 Tensile test measurements shall be carried out at the following ambient conditions:

Temperature — 23 ± 5°C

Humidity — 50 ± 5% RH

4 Sampling

4.1 The sampling is one sample per one lot. The vendor has to report the definition of lot, if the customer requires it.

4.2 The sample width shall be 15.0 ± 0.2 mm, and the length must be 100 mm minimum.

5 Equipment Setup and Calibration

5.1 Refer to the tensile tester manufacturer's equipment manual for setup and calibration.

5.2 The pulling rate shall be set to 5 ± 0.5 mm/minute.

5.3 The load shall be recorded in kilograms.

6 Procedure

6.1 Measure the thickness (T) of the sample with the micrometer and the width (W) with calipers (mm).

6.2 Clamp the tape in the chucks so that the distance (L_0) between the chucks is 50 ± 5 mm.

NOTE: Some equipment may measure this length automatically or plot Stress versus Strain, (L/L_0), directly, where L is the elongation.

6.3 Start the pulling and record until the sample breaks.

6.4 Repeat the testing procedures for all the samples.

7 Results

7.1 Read the Break Force A (kg) and Elongation L_1 (mm) at sample breakage from the chart.

7.2 Draw a tangent line from the origin of the Load-Elongation curve to the maximum slope of the curve. (See Figure 1.)

NOTE: B (kg) is the incremental force change required to produce an elongation, L_2, in the elastic region and may be determined from the tangent line.

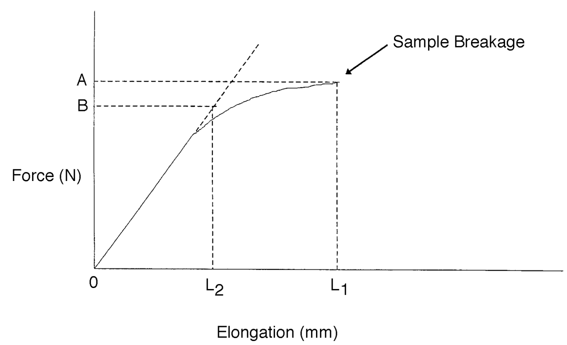

Figure 1
Breakage Point Calculation Diagram

7.3 *Calculations* — Tensile Strength at Break (s) is determined from the following equation:

$$S(N/mm^2) = \frac{9.8\,A}{WT}$$

7.3.1 Percentage Elongation at Break (e) is determined from the following equation:

$$\varepsilon(\%) = \frac{100\,L_1}{L_0}$$

7.3.2 Tensile Modulus (E) is determined from the following equation:

$$E(N/mm^2) = \frac{\Delta Stress}{\Delta Strain} = \frac{9.8B/WT}{L_2/L_0}$$

SEMI G75.10-0698
TEST METHOD FOR MEASUREMENT OF VOLUME AND SURFACE RESISTIVITY OF THE LEADFRAME TAPE

1 Summary of Method

1.1 A resistance is measured across the thickness and along the surface of the adhesive of tape between electrodes deposited on the tape. Volume and surface resistivity are calculated from these resistances and the dimensions electrodes.

2 Equipment

2.1 *Power Source* — 500 volts DC battery or 500 volts rectified voltage supply.

2.2 Amplified galvanometer should be used for measuring insulating resistance no less than $10^6\Omega$.

2.3 Electrostatically and electromagnetically shielded box

2.4 Humidity-controlled storage box

2.5 *Micrometer* — 0.001 mm accuracy

3 Sampling

3.1 The sampling is one sample per one lot. The vendor must report the definition of lot, if the customer requires it.

4 Preparation of Specimens

4.1 The specimen shall be punched out from tape, the diameter of which has to be no less than that of the opposite electrode.

4.2 Place the specimens in the constant humidity box 23° ± 2°C and 50 ± 5% RH for 90 ± 2 hours. This may also be done after the electrodes are formed.

5 Test Conditions

5.1 *Temperature* — 23° ± 2°C

5.2 *Relative Humidity* — 50 ± 5% RH

5.3 *Applied Voltage* — 500 volts

6 Procedure

6.1 Measure the thickness of specimen with the micrometer. Attach the electrodes to the specimen. Electrodes are formed by conductive epoxy printing or aluminum evaporation shown in Figure 1.

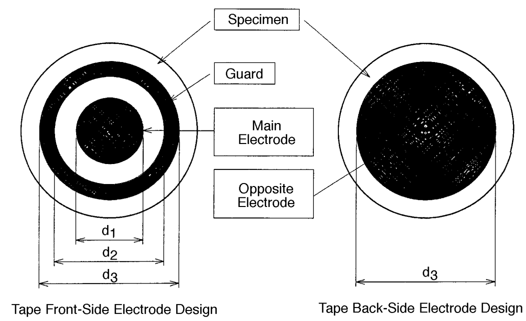

Figure 1
Electrodes Formed on the Leadframe Tape

NOTE 1: The electrodes shall be formed on both sides of the tape.

NOTE 2: Suggested dimensions for the electrodes as shown in Table 1 (d_1–d_2) should be at least 10 times the tape thickness.

Table 1 Suggested Dimension of the Electrodes

Suggested Dimension(for tape thickness 0.063–0.077 mm)	*Value*
d1	18 mm
d2	20 mm
d3	30 mm

NOTE 3: At surface resistivity measurement, main electrode and guard electrode is attached to the adhesive surface.

6.2 Place the specimens in the electrode system as shown in Figure 2A.

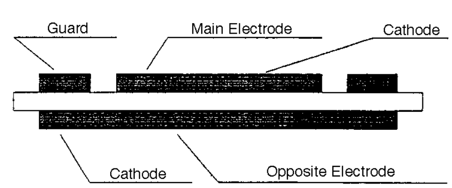

Figure 2A
Volume Resistivity Electrode Connection

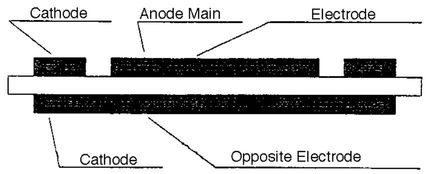

Figure 2B
Surface Resistivity Electrode Connection

6.3 Apply the specified voltage for one (1) minute and then read the resistance on the galvanometer.

6.4 Repeat the measurements for all the specimens.

6.5 Measure the thickness of the specimens using the micrometer.

6.6 *Calculations*

6.6.1 Volume resistivity should be calculated from the following equation:

$$\sigma v = \pi d_e^2 \times R_v / 4t$$

where :

σv	:	volume resistivity	Ωcm
d_e	:	effective diameter (41 +42)/2	cm
R_v	:	measured resistance cross tape thickness	Ωv/t
t	:	tape thickness	cm
d_1	:	inside diameter of the guard electrode	cm
d_2	:	outside diameter of the main electrode	cm

6.6.2 Surface resistivity should be determined from the following equation:

$$\sigma S = \pi (d_1 + d_2) \times R_s / (d_1 - d_2)$$

where :

σS	:	surface resistivity	Ω
d_1	:	inside diameter of the guard electrode	cm
d_2	:	outside diameter of the main electrode	cm
R_s	:	measured resistance along the adhesive surface side of tape thickness	Ω

Electrodes Formed on the Leadframe Tape

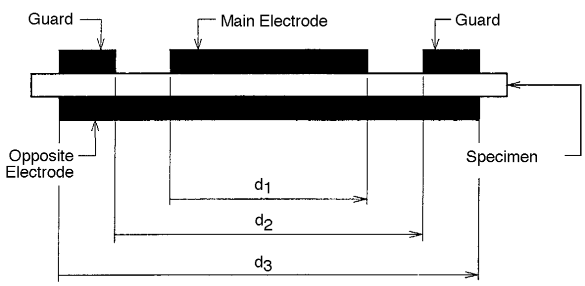

Figure 3
Electrode Connection

6.3 Dielectric constant and dielectric dissipation factor should be calculated by the following equation:

$$\varepsilon = C_x / C_o$$

$$\tan\delta = G_x / 2\pi f C_x$$

where :

ε : dielectric constant

tan : dielectric dissipation factor

C_x : capacity of measuring condenser C_c balances

C_o : electrostatic capacity for $\varepsilon = 1$ calculated by the following equation using the area of the main electrode and thickness of specimen

$$C_o = r^2 / 3.6\, t$$

where :

r : radius of main electrode

t : thickness of specimen

G_x : conductance of specimen calculated by the following equation

$$G_x = g \times Sv/100$$

where :

g : conductance between "m" and "d" of conductance shifter in Figure 1

Sv/100 : resistance ration of conductance shifter at balance

f : the frequency of measurement

: the ratio of the circle's circumference to its diameter

SEMI G75.12-0698
TEST METHOD FOR MEASUREMENT OF BREAKDOWN STRENGTH OF LEADFRAME TAPE

1 Summary of Method

1.1 An increasing voltage is applied between electrodes placed on both sides of the leadframe tape until breakdown, a large increase in current and voltage collapse, is observed.

2 Equipment

2.1 *Power Source* — DC High Voltage Generator (50 kv capability)

2.2 *Electrodes* — A brass spherical electrode with a diameter of 12.5 mm and a brass electrode with a diameter of 25 mm, which peripheral edges being rounded off to a radius of 2.5 mm. (See Figure 1.)

2.3 *Micrometer* — Accuracy 0.001 mm

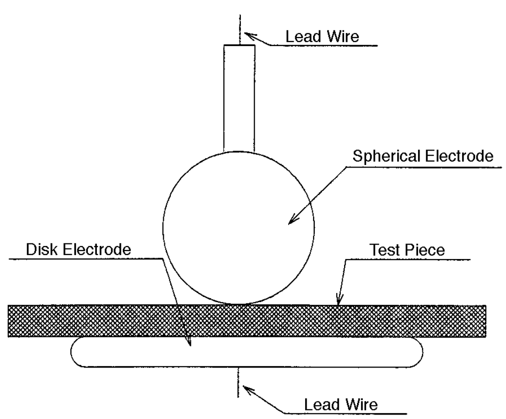

Figure 1
Electrodes for Measurement of Breakdown Strength

3 Sampling

3.1 The sampling is one sample per one lot. The vendor must report the definition of lot, if customer requires it.

4 Preparation of Specimens

4.1 Cut the specimens from the tape samples so that the size of the specimens is larger than the diameter of the disk electrode.

4.2 The specimens shall be stabilized in 23° ± 5°C and 50 ± 5% RH for 90 ± 2 hrs.

5 Test Conditions

5.1 *Temperature* — 23° ± 5°C

5.2 *Relative Humidity* — 50 ± 5% RH

6 Procedure

6.1 Place the specimens on the disk electrode and place the spherical electrode on the top of the tape. Ensure good contact between electrodes and tape.

6.2 *Setup Specimen*

6.2.1 Turn on the voltage supply and increase the voltage with constant ramp, until breakdown occurs.

NOTE 1: Note the voltage at breakdown. In subsequent specimens, arrange the voltage ramp so that the breakdown occurs approximately within 10–20 seconds after the beginning of voltage application.

6.3 Repeat the measurements for all the specimens.

6.4 Measure the thickness of the specimens using the micrometer.

6.5 *Calculations*

6.5.1 Breakdown strength should be calculated by the following equation:

$$\text{Dielectric Strength} \quad \frac{\text{kv}}{\text{mm}} = \frac{V_{BD}}{t}$$

where :

V_{Bd} = Breakdown voltage (kv)

t = tape thickness (mm)

SEMI G75.13-0698
TEST METHOD FOR MEASUREMENT OF THE LEAKAGE CURRENT IN LEADFRAME TAPE

1 Summary of Method

1.1 Taped leadframes are molded under normal conditions, and the leakage current between designated leads is measured before and after submitting the samples to HAST (121°C/2 atm/100% RH) moisture testing.

2 Equipment

2.1 HAST Chamber

2.2 Amperemeter with 10^{-15} ampere measuring capability

2.3 Power supply capable of 500 volts DC maximum

2.4 Electrostatically and electromagnetically shielded box

3 Sampling

3.1 The sampling is one sample per one lot. The vendor must report the definition of lot if the customer requires it.

4 Preparation of Specimens

4.1 Leadframes shall be cleaned up previous to taping, using a procedure agreed on between vendor and customer.

4.2 *Taping Conditions* — Temperature, pressure, and dwell time shall be agreed on between vendor and customer.

NOTE 1: A typical taped 40 pin DIP leadframe is shown in Figure 1, and relevant information for this frame is tabulated in Table 1.

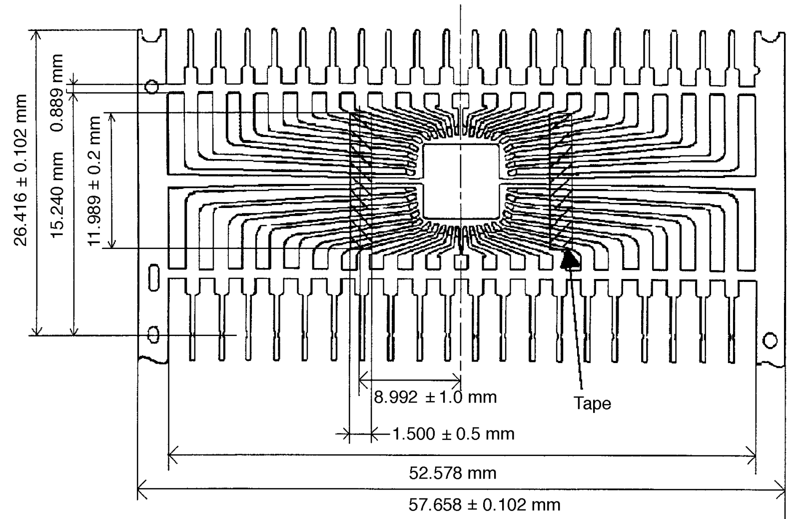

Figure 1
Typical Taped 40 Pin DIP Leadframe

Table 1 Relevant Information for 40 Pin DIP Leadframe

Leadframe Attribute	*Specification*
Leadframe thickness	0.25 mm
Leadframe material	Alloy 42
Leadframe manufacturing process	Stamping
Plating	None/Silver/Others
Surface treatment	To be agreed between tape user and supplier.

NOTE 2: The surface state of Alloy 42 is stable compared with Cu alloy, which is oxidized easily.

4.3 The leadframes shall be molded using molding compounds and cured with post mold curing conditions agreed on between vendor and customer. The untaped leadframe shall be prepared with the same procedure as a control.

4.4 Trim the leads according to a procedure agreed on between vendor and customer.

5 Procedure

5.1 Setup the test circuit as shown in Figure 2.

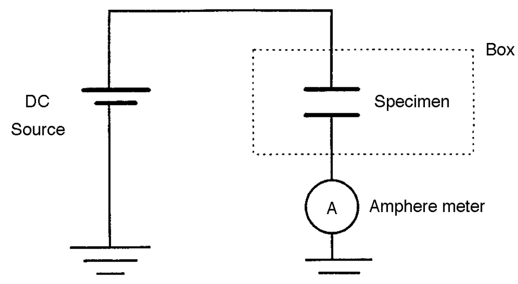

Figure 2
Test Circuit for Measurement of Leakage Current

5.2 Place the first molded sample in the shielded box and attach clips to the leads A_1 and A_2 (see Figure 1). Measure the initial leakage current at 500 volts maximum.

NOTE 3: The leakage current shall be measured after 5 minutes voltage application.

5.3 Repeat the measurement for all the lead pairs, A_2 with A_3, B_1 with B_2, and B_2 with B_3.

5.4 Place the samples in the HAST chamber and run the test.

5.5 After the tester has been automatically cooled to room temperature, remove the samples.

5.6 Measure the leakage current between the same lead pairs mentioned in Sections 5.2 and 5.3.

5.7 Repeat the HAST exposure and measure the cur-rent leakage.

5.8 *Calculation*

5.8.1 Maximum and minimum leakage current shall represent the test results.

5.8.2 Calculate the average result for all of the test points at each test stage.

5.8.3 Obtained data should be converted to 100 volts basis or as agreed on between vendor and customer.

SEMI G76-0299
SPECIFICATION FOR POLYIMIDE-BASED ADHESIVE TAPE USED IN TAPE CARRIER PACKAGES (TCP)

1. Purpose

1.1 This standard addresses the adhesive demands of tape carrier packages (TCPs) and how reliability, versatility and cost may be optimized. The standardization of polyimide adhesive tape used in TCP is being promoted in order to meet these demands.

2. Scope

2.1 This standard defines the standard for polyimide-based adhesive tapes (hereinafter "tape").

3. Referenced Documents

NOTE: Standards cited below refer to the latest adopted revision of the standard. *(Draft documents may not be referenced.)*

3.1 *JIS Standards*[1]

C-1303 — High Insulation Resistance Meters

C-2110 — Testing Methods for Electric Strength of Solid Insulating Materials

C-2318 — Polyester Films for Electrical Purposes

P-8101 — Testing Method for Dissolving Pulp

Z-3282 — Soft Solder

4. Terminology

4.1 *camber* — Curvature of the tape strip edge.

4.2 *machine direction (MD) curl* — Curvature along the length of the tape.

4.3 *tranverse direction (TD) curl* — Transverse bowing of the tape.

4.4 *twist* — Angular rotation of one end of the tape with reference to the other end.

4.5 *wakame* — Waviness along the edge of the tape.

5. Ordering Information

5.1 The following items shall be included in purchase orders for tape which conforms to this standard:

5.1.1 Type of adhesive material

5.1.2 Type of base film

5.1.3 Width of adhesive material

5.1.4 Width of base film

5.1.5 Length of product

6. Requirements

6.1 *Structure of Polyimide Adhesive Tape Used in TCP* — Adhesive material is applied to polyimide film defined in Section 6.2. When necessary, a protective film may be used to stop adhesion of the adhesive material to the back of the tape to prevent contamination of the adhesive material, improve puncture characteristics, etc.

6.2 *Base Film Thickness and Width*

6.2.1 *Base Film Thickness (see Table 1)*

Table 1. Base Film Thickness

Thickness (μm)	*Tolerance (μm)*
50.0	± 4.0
75.0	± 5.0
125.0	± 8.0

For thicknesses other than those above, use nominal value thickness denoted in μm.

6.2.2 *Base Film Width (see Table 2)*

Table 2. Base Film Width

Width (mm)	*Tolerance (mm)*
34.975	± 0.10
48.175	± 0.10
69.95	± 0.10

For widths other than those above, use nominal value width denoted in mm.

6.3 *Adhesive Material Thickness and Width*

6.3.1 *Adhesive Material Thickness (see Table 3)*

1 Japanese Standards Association, 1-24, Akasaka 4 Chome, Minato-ku, Tokyo, Japan

Table 3. Adhesive Material Thickness

Center Thickness t/µm	*Tolerance/µm*
10.0 ≤ t < 14.0	± 2.0
14.0 ≤ t < 20.0	± 3.0

For thicknesses other than those above, use nominal value thickness denoted in µm.

6.3.2 *Adhesive Material Width (see Table 4)*

Table 4. Adhesive Material Width

Width/mm	*Tolerance/mm*
29.7	± 0.1
42.7	± 0.1
60.6	± 0.1
64.4	± 0.1

For widths other than those above, use nominal value width denoted in mm.

6.4 *Distance from Edge of Base Film to Edge of Adhesive Material (see Table 5)*

Table 5. Distance from Edge of Base Film to Edge of Adhesive Material

Base Film Width/mm	*Adhesive Material Width/mm*	*Distance/mm*
34.975	29.7	≥ 2.40
48.175	42.7	≥ 2.40
69.95	60.6	≥ 4.40
69.95	64.4	≥ 2.40

6.5 *Cover Film Type, Thickness and Width*

6.5.1 *Cover Film Thickness (see Table 6)*

Table 6. Cover Film Thickness

Thickness at Center/µm	*Tolerance/µm*
10.0–50.0	± 2.0

For thicknesses other than those above, use nominal value thickness denoted in µm.

6.5.2 *Cover Film Width* — Use the same measurements as found in Section 6.3.2.

6.6 *Adhesive Tape Thickness and Tolerance*

6.6.1 *Adhesive Tape Thickness* — Use the sum of the nominal thicknesses of the base film, adhesive material and cover film.

6.6.2 *Tolerance* — Use the sum of the nominal tolerances of the base film, adhesive material and cover film.

6.7 *Characteristics (see Table 7)*

Table 7. Characteristics of Adhesive Tape

Item	*Condition*	*Unit*	*Test Method*	*Value*
Copper Foil Adhesive Strength	Normal	N/cm	8.5.1 (a)	> 5
	Heated	N/cm	8.5.1 (b)	> 1
	Soaked in solvent	N/cm (see NOTE 3)	8.5.1 (c)	> 3
Cover Film Release Strength	Normal	N/cm	8.5.2	< 0.2
Insulation Resistance	Normal	Ω	8.6.3 (3)(a)	Not Specified
	In High Temp. High Humidity	Ω (see NOTE 4)	8.6.3 (3)(b)	Not Specified
	In High Temp. High Humidity, Under Bias	Ω (see NOTE 5)	8.6.3 (3)(c)	Not Specified
Volume Resistivity	Normal	Ω-cm	8.6.1	$> 10^{13}$
Surface Resistivity	Normal	Ω	8.6.2	$> 10^{10}$
Voltage Resistance	Normal	Ω	8.6.4	No Flash-over
Relative Permittivity	Normal	-	8.6.5	< 4.0
Dielectric Dissipation Factor	Normal	-	8.6.5	< 0.07
Solder Heat Resistance	Normal	-	8.7.1	No Delamination No Swelling
Heat Shrinkage	Normal	%	8.7.3	< 0.5
Coefficient of Thermal Expansion	-	cm/cm/°C	8.7.4	$< 3.0 \times 10^{-5}$
Tensile Strength	-	Mpa	8.7.5	> 100
Elongation	Normal	%	8.7.5	> 20
Water Absorption	Normal	%	8.7.2	< 4.0
Flammability	Normal	-	8.7.6	Not Specified

NOTE 1: *Normal Condition* — Normal condition refers to a temperature of 23 ± 5°C, and relative humidity of 55 ± 15%.

NOTE 2: *Heated Condition* — See Section 8.5.1, (3)(b).

NOTE 3: *Soaked in Solvent* — See Section 8.5.1, (3)(c).

NOTE 4: *High Temperature, High Humidity* — See Section 8.6.3, (3)(b).

NOTE 5: *High Temperature, High Humidity, Under Bias* — See Section 8.6.3, (3)(c).

6.8 *Appearance and Defects* — See Table 8. Width and thickness for the base film, adhesive material and cover film are not particularly specified.

Table 8. Appearance and Defects

Item	*Test Method*	*Unit*	*Value*
MD Curl	8.8.1	mm	< 15
TD Curl	8.8.2	mm	< 6
Wakame	8.8.3	Number/m	< 20 of < 2 mm, 0 of > 2 mm
Camber	8.8.4	mm/m	< 1
Twist	8.8.5	Degrees	< 135
Defect	8.8.6	#/m or #/100m	< 5/m between 0.1 mm^2 and 1mm^2 or, < 10/100 m of > 1 mm^2

7. Sampling

A sampling plan shall be defined between the user and supplier.

8. Test Methods

8.1 *Test Conditions*

8.1.1 *Normal* — Normal condition refers to a temperature of 23 ± 5°C, and relative humidity of 55 ± 15%.

8.2 *Materials*

8.2.1 *Material Preparation* — Unless otherwise specified, take the needed length of material from the inner part of the roll after peeling off the first three layers.

8.2.2 *Lamination* — Use the following steps to prepare materials which require lamination:

(1) *Material* — Unless otherwise specified, use a copper foil which has previously been decided upon by the user and supplier.

(2) *Lamination Method* — Unless otherwise specified, a method used shall be agreed between user and supplier.

(3) *Curing* — Unless otherwise specified, a method used shall be agreed between user and supplier.

8.2.3 *Etching* — For material which requires etching, unless otherwise specified, a method used shall be agreed between user and supplier.

8.2.4 *Plating* — For material which requires plating, unless otherwise specified, a method used shall be agreed between user and supplier.

8.2.5 *Test Pattern* — The pattern used in Figure 1 is recommended for the shape and dimensions of the test pattern. Where this is not applicable, a pattern used shall be agreed between user and supplier.

8.3 *Pre-Conditioning* — Unless otherwise specified, leave the sample materials in normal condition for 24 ± 4 hours.

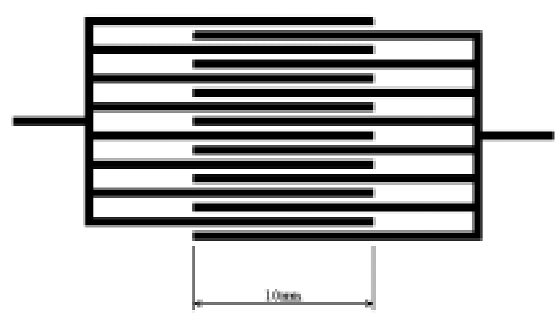

Figure 1
Test Pattern

Table 9. Test Pattern

Line Pitchs (µm)	*Line Widths (µm)*	*Line Spacings (µm)*
90	45	45
70	35	35
60	30	30
50	25	25
40	20	20

8.4 *Dimension Test Procedure*

8.4.1 *Thickness*

(1) *Equipment* — Use a micrometer standardized to JIS C-2318 or equivalent.

(2) *Material* — Use the TCP polyimide adhesive tape as received from the supplier.

(3) *Measurement* — Measure the center, and 3 points at least 1m apart in the MD direction, and calculate the average.

8.4.2 *Width*

(1) *Equipment* — Use a projector capable of reading a minimum of 0.001 mm integrals.

(2) *Material* — Use the TCP polyimide adhesive tape as received from the supplier.

(3) *Measurement* — Measure the TD direction length in 3 points at least 1m apart in the MD direction, and calculate the average.

8.5 *Mechanical Efficiency Tests*

8.5.1 *Copper Foil Adhesive Strength*

(1) Equipment

(a) A pull tester with an appropriate measurement range, having a tolerance of ± 5% of the indicated value, and capable of maintaining a cross-head speed of 10–50 mm/min.

(b) A pull tester with a sample retention heating device or sample chamber for retaining surface temperature for measuring conditions.

(2) Material

(a) *Normal* — Use a sample with copper etching and conductor width of 50 ± 10 µm and conductor length of more than 30 mm. The measurement direction and number of samples should be previously determined by the user and supplier. Unless otherwise specified, use 2 samples and measure in the MD direction.

(b) *Heated* — Use the same as (a), except with a conductor width of 2 ± 0.5 mm.

(3) Measurement

(a) *Normal* — After measuring the sample conductor width, fix the sample in the pull tester. In order to keep peeling angle at 90°, affix a reinforcement panel with double-sided adhesive tape. Pull and peel off more than 20 mm of copper foil at a speed of 10 mm/min^{-1} and an angle of 90 ± 5°. Measure the load during this interval.

(b) *Heated* — Fix the sample in retention heating device of the pull tester and raise the temperature, or, fix the sample in a previously retention heating device in the pull tester. It is also feasible to use a sample chamber which can heat the whole sample. Measure the sample surface temperature with a contact surface thermometer, and when a temperature of 150 ± 5°C is confirmed, quickly pull and peel off more than 20 mm of copper foil at a speed of 10 mm/min^{-1} and an angle of 90 ± 5°. Measure the load during this interval.

(c) *Soaked in Solvent* — After soaking the sample in a specified solvent at 23 ± 5°C for 5 minutes, remove the sample and rinse and dry off solvent thoroughly. Place in normal conditions, as described in Section 8.1.1, for 24 ± 4 hours and perform the same test as above "normal" (3)(a). However, if the solvent is inorganic, wash sample well with water after taking it out of the solvent and dry at 80 ± 5°C for 30 minutes. Then place in normal conditions, as described in Section 8.1.1, for 24 ± 4 hours and perform the same test as above "normal" (3)(a). The type and condition of the solvent used shall be agreed between the user and supplier.

(4) Calculation

(a) Compile the measurements, leaving out the overshoot at the beginning and end, and calculate the average of samples with a stable section of 10 mm. The method of calculating the average should be predetermined by the user and supplier. Unless otherwise specified, place a ruler over the chart and determine visually.

(b) Calculate the load on pulling and peeling off of each sample, excluding the samples conductor width, and the average will be the copper foil adhesive strength.

8.5.2 *Cover Film Release Strength*

(1) *Equipment* — Use the same equipment as in Section 8.5.1 (1).

(2) *Material* — Use a 250 mm section cut from the TCP polyimide adhesive tape as received from the vendor.

(3) *Measurement* — After measuring the sample cover film width, fix the sample in the pull tester. In order to keep the sample at 90°, affix a reinforcement panel with double-sided adhesive tape. Pull and peel off more than 50 mm of cover film at a speed of 50 mm/min^{-1} and an angle of 90 ± 5°. Measure the load during this interval.

(4) *Calculation* — Use the same method as Section 8.5.1, (4).

8.6 *Electrical Efficiency Test*

8.6.1 *Volume Resistivity*

(1) *Equipment* — Use high insulation-resistance meter which conforms to JIS C-1303, or similar resistance measuring device (see Figure 2).

(2) *Material* — Prepare a section of TCP polyimide adhesive tape with adhesive material width of more than 50 mm, laminate with copper foil and cure according to the method described in Section 8.2. In addition, etch the main electrode and guard electrode into the shapes found in Figure 3. For the counter electrode, melt on a conductive material to the opposing polyimide film surface, or form it out of conductive paste. Dry these at 80 ± 5°C for 30 minutes. Cut these into 50 mm squares for the material.

(3) *Measurement* — Use the following steps to measure under normal conditions: Measure the thickness of the samples in units of 0.1 µm, and measure the inner diameter of the gap in the circular upper electrode in units of 0.05 mm. Apply direct voltage of 500V ± 5V, and measure the resistance value after 1 minute.

(4) *Calculation* — Use the equation below.

$$\rho v = Rv \times \frac{\pi D_1}{4t} (\Omega / cm)$$

Where ρv is volume resistivity, Rv is resistance value, t is sample thickness, π is pi, and D_1 is main electrode outer diameter.

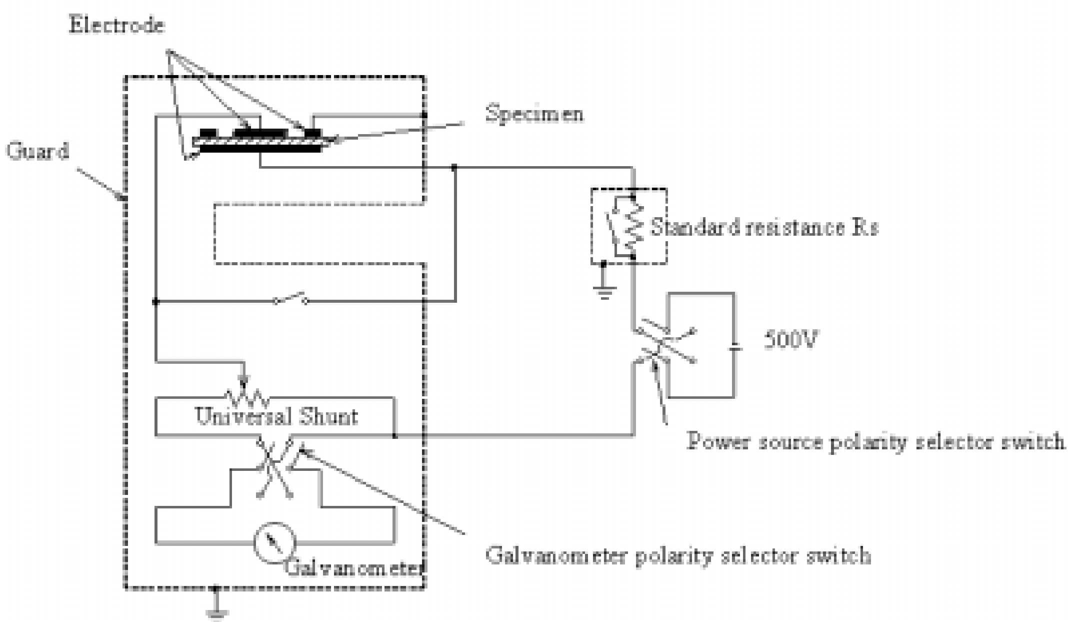

Figure 2
Resistance Measurement Device for Volume Resistivity

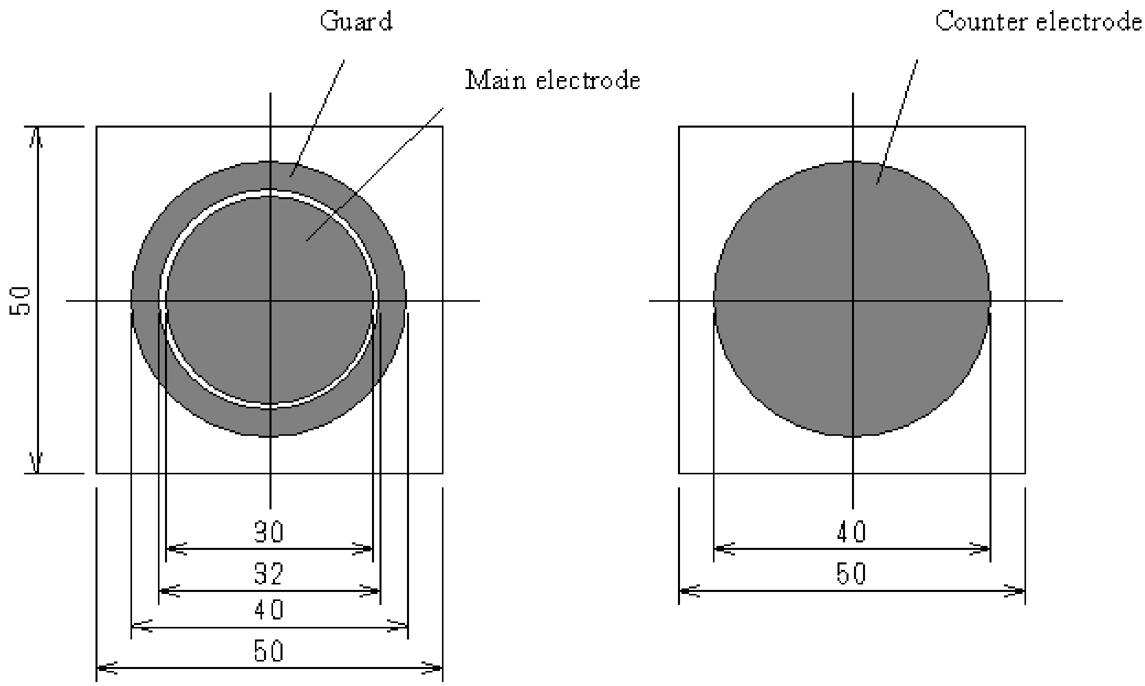

Figure 3
Electrodes for Measurement of Volume Resistivity

8.6.2 *Surface Resistivity*

(1) *Equipment* — Use the same equipment as in Section 8.6.1.

(2) *Material* — Use the same material as in Section 8.6.1.

(3) *Measurement* — To measure Surface Resistance in normal conditions, use the same method as described in Section 8.6.1.

(4) *Calculation* — Use the equation below.

$$\rho s = Rs \times \frac{P}{D_0} (\Omega)$$

Where ρs is Surface Resistance, Rs is resistance value, P is the actual circumference length of the guarded electrode, and D_0 is the distance between the main electrode and the guard electrode.

8.6.3 *Insulation Resistance*

(1) Equipment

(a) *Resistance Meter* — Use the same equipment as in Section 8.6.2.

(b) *Direct Current* — Use a stabilized direct power supply that can apply a stable 100 ± 5V to the sample.

(c) *Environmental Test Chamber* — Use an oven with terminal connectors on the outside which can maintain humidity at 30–85 ± 5°C and 60–90 ± 5% R.H.

(2) *Material* — Using the TCP polyimide adhesive tape as received from the vendor, laminate and cure it according to the method described in Section 8.2.

(3) Measurement

(a) *Normal Condition* — Apply direct voltage of 100 ± 5V to the sample and maintain for 1 minute. Keeping the voltage applied, measure the insulation resistance.

(b) *High Temperature, High Humidity* — After keeping the sample under 85 ±

5°C and 85 ± 5% R.H. for 24 ± 4 hours, perform the same measurement as in Section 8.6.3, (3)(a).

(c) *High Temperature, High Humidity, Under Bias* — After keeping the sample under 85 ± 5°C and 85 ± 5% R.H. for 24 ± 4 hours, apply direct voltage of 100 ± 5V and perform the same measurement as in Section 8.6.3, (3)(a). After this, follow the methods and conditions defined by the receiving parties.

8.6.4 *Inter-Layer Voltage Resistance*

(1) *Equipment* — Use the equipment which conforms to JIS C-2110, Section 6.2 or similar.

(2) *Material* — Use the same material prepared by the same method as in Section 8.6.1, (2).

(3) *Measurement* — To measure in normal conditions, perform the following steps: Using DC voltage, or a sine wave AC with 50 or 60 Hz frequency, apply 500V to the sample. Increase the applied voltage up to the defined voltage over 5 seconds, maintain it for 1 minute and determine whether there has been any mechanical damage, flash-over, spark-over, insulation breakdown or other abnormality.

8.6.5 *Relative Permittivity and Dielectric Dissipation Factor*

(1) Equipment

(a) *Power Source (see Figure 4 - S)* — Use a source which can emit a frequency of 1 MHz, has a sine wave with less than 5% distortion factor, can give a stable flow of the define voltage to the sample, and have electro-static and magnetic shielding to prevent direct coupling between the power source and bridge.

(b) *Shielded Transformer (see Figure 4 - T_1)* — Use a transformer with which the power source internal impedance and the bridge impedance can be adjusted, and one where the winding on the bridge inside the transformer is shielded with a grounded conductor.

(c) *Ratio Arm (see Figure 4 - T_2)* — Use a ratio arm with a winding ratio of 1:1 (tolerance of less than 0.2%). Make a non-inductive connection of the primary winding and secondary winding of a transformer with as little leakage inductance and winding resistance. Ground the connection point as shown in Figure 4 - e, and connect the other 2 terminals to l and r to make it unbalanced.

(d) *Variable Capacitor (see Figure 4 - Cs_1, Cs_2)* — Use two air capacitors with guards that have a capacity of approximately 200 pF, one being the standard capacitor Cs_1 and the other being the measuring capacitor Cs_2, and insert parallel with the sample Cx.

(e) *Conductance Shifter (see Figure 4 - g)* — Insert a resistor with a constant conductance in between m and d in Figure 4, where the resistance between l and m can be changed between 100–0 Ω, and the resistance between m and r can be changed between 100–200 Ω.

(f) *Balance Detector (see Figure 4 - g)* — Use a balance detector which responds only to the power source voltage base plate used in the bridge.

(2) *Material* — Prepare the samples according to the method described in Section 8.6.1, (3). Use Figure 3 for the shape of the electrode.

(3) *Measurement* — Use the following to measure under normal conditions: Measure the thickness of the samples in units of 1 μm, and measure the inner diameter of the gap in the circular upper electrode in units of 0.05 mm. Also, confirm that the circular gap between the main electrode and the guard electrode is 1 ± 0.1 mm. Connect the sample at position Cx, and by adjusting the measuring capacitor Cs_2 and the conductance shifter, with the bridge balanced, measure the standard capacitor Cs_1 value and the measuring capacitor Cs_2 value, the resistance value between conductance shifter m and d, and the resistance value between m and r. The measuring frequency is 1 MHz.

(4) *Calculation* — Use the equation below.

(a) Relative Permittivity

$$\varepsilon r = \frac{Cx}{C_0}(\Omega)$$

Where Cx is the difference in the capacitance values of standard capacitor Cs_1 and measuring capacitor Cs_2 (when the bridge is balanced, and C_0 is the electrostatic capacity where εr = 1 calculated from the main electrode area and sample thickness according to the following formula):

$$C_0 = \frac{r^2}{3.6t}$$

(b) Dielectric Dissipation Factor

$$\tan\delta = \frac{Gx}{2\pi f Cx}$$

$$Gx = G \times \frac{S}{100}$$

Where Gx is the sample conductance, G is the conductance between m and d, S is the resistance value between m and r, S/100 is the resistance factor, f is the measuring frequency, and π is pi.

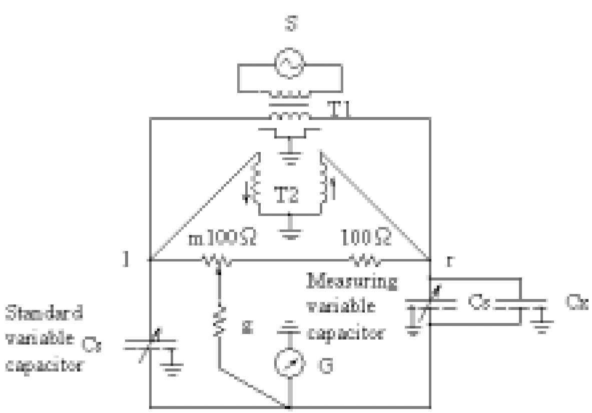

Figure 4
Measurement Circuit for Relative Permittivity and Dielectric Dissipation Factor

8.7 *Other Tests*

8.7.1 *Heat Resistance*

(1) Equipment

(a) *Solder* — Use Standard H60A or H63A under JIS Z-3282.

(b) *Solder Bath* — A vessel with a depth of more than 50 mm to hold the solder at between 200–300°C and can be adjusted ± 3°C.

(1) *Material* — Using the TCP polyimide adhesive tape as received from the vendor, laminate and cure it according to the method described in Section 8.2. Cut into 25 mm squares for samples.

(2) *Preparation* — Keep in 105 ± 5°C oven for 1 hour.

(3) *Test* — After preparation, quickly place in 260 ± 5°C solder bath and let float for 5^{+1}_{-0} seconds. Perform visual check for swelling.

8.7.2 *Water Absorption Test*

(1) Equipment

(a) *Scale* — Use a scale that can measure in 1 mg units.

(b) *Vessel* — Use a vessel in which the samples can be totally immersed.

(c) *Dessicator* — Use a dessicator which allows samples heated to 80°C to cool off.

(1) *Material* — Using the TCP polyimide adhesive tape as received from the vendor, laminate and cure it according to the method described in Section 8.2. In addition, remove all copper foil by etching, and dry for 30 minutes at 80 ± 5°C. Cool in the dessicator, and use samples cut into length 500 ± 5 mm, and width 20 ± 1 mm. Depending on the shape of the vessel to be used for immersion, it is feasible to several pieces of a suitable length.

(2) *Test* — Weigh the sample in increments of 1 mg. Place sample in 23 ± 2°C distilled water. After 24 ± 1 hours, wipe off water and measure sample again in increments of 1 mg.

(3) *Calculation* — Use the following formula:

$$\frac{W_2 - W_1}{W_2} \times 100 \qquad (\%)$$

Where W_1 and W_2 are the weight before and after immersion respectively.

8.7.3 *Heat Shrinkage* — Use the standard value of the base film and the various values for measuring conditions.

(1) *Equipment* — Use a measuring device with optical equipment which can read with at least 5/100,000 (0.005%) precision.

(2) *Material* — Mark three places along the width on a sample with size larger than 50 mm square.

(3) *Preparation* — Place for more than 1 hour in a managed environment of room temperature ± 2°C, ± 5% R.H.

(4) *Measuring Method Before Heating* — Measure the distance between the marks with the equipment (1) on a sample that has been prepared according to (3) above.

(5) *Heating* — Keep the samples in an oven at 200 ± 3°C for more than an hour, making sure that it is not effected from the outside.

(6) *After-Processing* — Leave sample for more than 1 hour in the conditions described in (3) above.

(7) *Measuring Method After Heating* — Use the same method as (4) above.

(8) *Calculation* — Use the following formula, where L_1 is the dimension from (4), and L_2 is the dimension from (7):

$$\frac{L_1 - L_2}{L_1} \times 100 \qquad (\%)$$

8.7.4 *Coefficient of Thermal Expansion* — Use the standard value of the base film and the various values for measuring conditions.

(1) *Equipment* — Use TMA equipment.

(2) *Material* — Prepare sample with width of 3 mm and length of more than 15 mm.

(3) *Preparation* — To remove the effects of thermal shrinkage and moisture, heat at more than 300°C for 30 minutes.

(4) *Measuring Method* — With a sample that has been prepared according to (3) above, measure the stretching in the sample on a TMA, in the range between room temperature and 300°C, raising the temperature at less than 20°C/min.

(5) *Calculation* — Use the following formula, reading a gradient from an arbitrary scope, within the area between room temperature and 200°C (i.e., 50–200°C, 100–200°C):

$$\frac{L_1 - L_0}{L_0 (T_1 - T_0)} \times 100^{6} \qquad (ppm)$$

Where T_0 and T_1 are the temperatures in the area for Linear Expansion, L_0 is the length of the sample at T_0 (°C) and L_1 is the length of the sample at T_1 (°C).

8.7.5 *Tensile Strength, Elongation* — Use the standard value of the base film and the various values for measuring conditions.

(1) *Equipment* — Use a pull strength meter and recorder.

(2) *Material* — Use samples with a width of more than 10 mm and length of approximately 200 mm. The samples should be 3 pieces taken from the beginning, middle and end of the roll.

(3) *Measuring Method* — After measuring the width of the sample, fix it in the pull strength meter. Use a clamping distance of approximately 100 mm to test pull strength. Measure the pull load and stretch at point of breakage.

(4) *Calculation* — After measuring the pull strength and elasticity of each sample, calculate the average of each.

8.7.6 *Flammability*

(1) Equipment

(a) Sample box or draft chamber which can maintain calm conditions.

(b) Test stand and clamp.

(c) Bunsen burner with pipe length of approximately 100 mm, aperture diameter of 9.5 ± 0.5 mm, using methane gas or natural gas with a heat generation volume of approximately 37 MJ/m^3.

(d) Stop-watch or timer.

(e) Sheet of absorbent cotton 50 mm square with a maximum natural thickness of 6.4 mm.

(f) A dessicator with dehydrated hydrated calcium.

(g) A test oven which can maintain a temperature of 23 ± 2°C and R.H. of 50 ± 5%.

(h) A test oven which can maintain a temperature of 70 ± 1°C.

(i) A pole with a diameter of 13 ± 5 mm.

(2) *Material* — Using the TCP polyimide adhesive tape as received from the vendor, laminate and cure it according to the method described in Section 8.2. In addition, remove all copper foil by etching, and dry for 30 minutes at 80 ± 5°C. As shown in Figure 5, use a sample with a length of 200 mm and width of 50 mm, and mark a line in the TD direction at 125 mm from the bottom. With the mark line facing outward, wrap the sample around the pole and hold in place with tape within 76 mm about the mark line. Remove the pole to leave a tube of the sample. Prepare 2 groups of 5 pieces each.

(3) *Preparation* — Leave one group of samples in normal condition for 48 hours. Heat the other group at 70 ± 1°C for 168 hours, place them in the dessicator with dehydrated hydrated calcium and keep for more than 4 hours at 23°C.

(4) *Test* — Perform the following test on the two groups of samples prepared as described in Section 8.7.6, (3) above:

(a) As shown in Figure 6, fix the sample perpendicular in the ring stand with the clamps, with the tip of the burner 10 mm below the edge of the sample, and the absorbent cotton placed horizontal at 300 mm below the edge.

(b) Light the burner away from the sample, and adjust to a blue flame of 20 ± 1 mm long. Keeping the length at 20 ± 1 mm, make sure there is no yellow flame at the tip.

(c) Apply the flame to the center of the edge of the sample for 3 seconds. Then remove the flame to more than 150 mm away, and record the flaming time. When the flame burns out, apply the flame to the edge of the sample for 3 seconds and pull away again. Measure the flaming time it takes to reach the clamp as well as the glowing time. Also, record whether the absorbent cotton has caught fire or not. When there are molten particles or burning material drippings from the sample, it is acceptable to tip the burner 45° and move the flame from the bottom edge to avoid material dripping on the burner. In this case, the distance from the bottom edge of the sample to the tip of the burner should still be 10 mm.

(5) Items to Record

(a) Flaming time after the first and second application.

(b) Sum of flaming and glowing time after second application.

(c) Flaming or glowing up to the clamp or mark line.

(d) Existence of dripping material which caused the absorbent cotton to burn.

8.8 *Test for External Defects*

8.8.1 *MD Curl*

(1) *Equipment* — Use a scale that measures at least 1 mm increments.

(2) *Material* — Cut a section of more than 30 cm, but less than 100 cm in length of TCP polyimide adhesive tape as received.

(3) Measurement — As shown in Figure 7, remove the cover film, place on a flat surface for more than 12 hours and measure the highest point on the tape from the flat surface in the MD direction.

8.8.2 *TD Curl*

(1) Equipment

(a) A scale that measures at least 1 mm increments.

(b) A square block with a base with a length of more than 15 cm and width of 2 cm, and a weight of more than 500 g.

(2) *Material* — Cut a section of more than 15 cm, but less than 30 cm in length of TCP polyimide adhesive tape as received.

(3) Measurement

(a) Remove the cover film and place on a flat surface for more than 12 hours.

(b) Use the block to hold down the sample tape on the edge without adhesive. The space held down should be more than 2 mm in from the edge, but before the adhesive material.

(c) As shown in Figure 8, on the opposite side of the tape for the block, measure the highest point from the flat surface.

8.8.3 *Wakame*

(1) *Equipment* — Use a scale that measures at least 1 mm increments.

(2) *Material* — Cut a section of more than 30 cm, but less than 100 cm in length of TCP polyimide adhesive tape as received.

(3) *Measurement* — As shown in Figure 9, place on a flat surface for more than 12 hours and calculate the number of points off the flat surface less than 2 mm high.

8.8.4 *Camber*

(1) *Equipment* — Use a scale that measures at least 1 mm increments.

(2) *Material* — Cut a section of more than 30 cm, but less than 100 cm in length of TCP polyimide adhesive tape as received.

(3) *Measurement* — As shown in Figure 10, connect corners of the tape in a straight line, and measure the deviation from the line to the edge of the tape at the center.

8.8.5 *Twist*

(1) *Equipment* — Use a protractor that measures at least 1 degree increments.

(2) *Material* — Cut a section of 1 meter in length of TCP polyimide adhesive tape as received.

(3) *Measurement* — Hang the tape vertically and measure the angle of twist of the bottom edge as opposed to the top edge.

8.8.6 *Defects*

(1) *Equipment* — Use a 10 power magnifying glass or naked eye.

(2) *Material* — Use TCP polyimide adhesive tape as received. The length should be determined between the user and supplier.

(3) *Measurement* — Perform a check on defects against a limit sample determined by the user and supplier. Unless otherwise specified, the "Admixture Measurement Table" from the JIS P-8101 standard (Finance Ministry Printing Press) is recommended.

9. Product Labeling

Note the following items on the product label:

(1) Type Name

(2) Product Width

(3) Product Length

(4) Lot Number

10. Packing and Package Labeling

10.1 *Packing* — Pack the product with sufficient packing material to prevent any effects from external impact, moisture, etc.

10.2 *Package Label* — Note the following items on the packaging label:

(1) Product Name

(2) Type Name

(3) Manufacturer's Name

(4) Product Width

(5) Product Length

(6) Lot Number

(7) Storage Conditions

SEMI G77-0699
SPECIFICATION FOR FRAME CASSETTE FOR 300 MM WAFERS

This test method was technically approved by the Global Assembly & Packaging Committee and is the direct responsibility of the Japanese Packaging Committee. Current edition approved by the Japanese Regional Standards Committee on March 17, 1999. Initially available at www.semi.org May 1999; to be published June 1999.

1 Purpose

1.1 The purpose of this document is to specify the mechanical features for a 300 mm wafer frame cassette used between the wafer mounting process and the die-bonding process.

2 Scope

2.1 This standard is intended to set an appropriate level of specification that places minimal limits on innovation while ensuring modularity and interchangeability at all mechanical interfaces.

2.2 Only the physical interfaces for the frame cassette are specified; no materials requirements or micro-contamination limits are given. However, this specification was written to allow for both metal and plastic frame cassette designs.

2.3 This specification defines a 300 mm wafer frame cassette that is intended for both manual and automated transport. The frame cassette has the following components and sub-components (“ ” indicates an optional component):

2.3.1 Top

robotic handling flange (optional)

- top cover

2.3.2 Interior

- frame supports for 13 or 25 tape frames
- frame restraint

2.3.3 Sides

human handles (optional)

2.3.4 Rear

- rear cover

2.3.5 Bottom

- 2 bottom conveyor rails running along the sides of the frame cassette

3 features that mate with kinematic coupling pins and provide a 10 mm lead-in (optional)

4 frame cassette sending pads (optional)

3 Referenced Documents

3.1 *SEMI Standards*

SEMI E1.9 — Provisional Mechanical Specification for Cassettes Used to Transport and Store 300 mm Wafers

SEMI E15 — Specification for Tool Load Port

SEMI E47.1 — Provisional Mechanical Specification for Boxes and Pods Used to Transport and Store 300 mm Wafers

SEMI E57 — Provisional Mechanical Specification for Kinematic Couplings Used to Align and Support 300 mm Wafer Carriers

SEMI G74 — Specification for Tape Frame for 300 mm Wafers

SEMI S8 — Safety Guidelines for Ergonomics/Human Factors Engineering of Semiconductor Manufacturing Equipment

4 Terminology

4.1 *bilaterial datum plane* — a vertical plane that bisects the tape frames and that is perpendicular to both the horizontal and facial datum planes (as defined in SEMI E57).

4.2 *conveyor rails* — parallel surfaces on the bottom of the cassette for supporting the cassette on roller conveyors.

4.3 *facial datum plane* — a vertical plane that bisects the tape frames and that is parallel to the front side of the frame cassette (where tape frames are removed or inserted). On tool load ports, it is also parallel to the load face plane specified in SEMI E15 on the side of the tool where the frame cassette is loaded and unloaded (as defined in SEMI E57).

4.4 *frame cassette* — an open structure that holds one or more tape frames.

4.5 *horizontal datum plane* — a horizontal plane from which projects the kinematic coupling pins on which the frame cassette sits. On tool load ports, it is at the load height specified in SEMI E15 and might not be physically realized as a surface (as defined in SEMI E57).

4.6 *robotic handling flange* — horizontal projection on the top of the frame cassette for lifting and rotating the frame cassette.

4.7 *tape frame* — the frame which applies the wafer tape to the wafer and retains the wafer.

4.8 *wafer tape* — an adhesive plastic tape which retains the wafer or diced chip. It is used between the mounting process and die-bonding process.

5 Ordering Information

5.1 *Intended use* — This document is intended to specify 300 mm wafer frame cassettes over a reasonable lifetime of use, not just those in new condition. For this reason, the purchaser needs to specify a time period as well as the number and type of uses to which the frame cassettes will be put. It is under these conditions that the frame cassettes must remain in compliance with the requirements listed in Section 6.

6 Requirements

6.1 *Dimensions* — The frame cassette dimensions are shown in Figures 1 through 5 and listed in Table 1. In all figures, the heaviest lines are used for surfaces that have tolerances (not surfaces that have only maximum or only minimum dimensions).

6.2 *Tape Frame Orientation* — The tape frames must be horizontal when the frame cassette is placed on the load port.

6.3 *Center of Tape Frames* — When a tape frame is stored in the frame cassette, the center of the tape frame should be within the radius of 2 mm from the center of the junction of the bilaterial datum plane and the facial datum plane.

6.4 *Top and Rear Covers* — Both top and rear covers are required. With the covers in place, the frame cassette must conform to all dimensions listed in Table 1.

6.5 *Number of Slots* — The frame cassette has an option of either 13 or 25 slots.

6.6 *Kinematic Couplings (optional)* — The physical alignment mechanism from the frame cassette to the tool load port (or a nest on a vehicle or in a stocker) consists of features (not specified in this document) on the top entity that mate with three or six pins underneath as defined in SEMI E57. Most of the dimensions of the frame cassette are determined with respect to the three orthogonal datum planes defined in that standard: the Horizontal Datum Plane, the facial datum plane, and the bilateral datum plane.

6.6.1 The three features that mate with the pins must provide a lead-in capability that corrects a frame cassette misalignment of up to 10 mm in any horizontal direction, although 15 mm is recommended for ergonomic reasons. However, it is recommended that robotics placing cassettes on kinematic couplings use as little of this lead-in capability as possible to avoid wear.

6.7 *Human Handles (optional)* — All handles for use by humans must either be contained within the maximum outer dimensions of the frame cassette, be detached when not in use, or be retractable into the maximum outer dimensions when not in use. Handles for use by humans (if present) must follow SEMI S8 and shall require the use of both hands (each using a full wrap-around grip, given the minimum clearance requirement in SEMI E15.1). Automation handling features shall not be considered for dual purpose unless they are designed to meet SEMI S8.

6.8 *Robotic Handling Flange (optional)* — On the top of the frame cassette is an optional robotic handling flange for manipulating the frame cassette.

6.9 *Bottom Rails* — On the bottom of the frame cassette are two rails, one on each side for use with roller conveyors.

6.10 *Frame Restraint* — The frame cassette must provide a feature that prevents tape frames from slipping out of the cassette during transport. The feature must conform to all dimensions listed in Table 1.

6.11 *Frame Cassette Sensing Pads (optional)* — When the cassette is fully down, the frame cassette sensing pads (see Figure 5) must be z2 above the horizontal datum plane. It is recommended that the areas surrounding all of the frame cassette sensing pads be designed in conjunction with the features that mate with the kinematic coupling pins so that a mechanical sensor pin cannot interfere with the lead-in function of the kinematic couplings.

6.12 *Cassette Stacking (optional)* — The frame cassette may have optional features to allow two 13 capacity cassettes to be stacked on top of each other. This option is only available for cassettes without a robotic handling flange.

SEMI G78-0699
TEST METHOD FOR COMPARING AUTOMATED WAFER PROBE SYSTEMS UTILIZING PROCESS-SPECIFIC MEASUREMENTS

This test method was technically approved by the Global Automated Test Equipment Committee and is the direct responsibility of the North American Automated Test Equipment Committee. Current edition approved by the North American Regional Standards Committee on December 18, 1998. Initially available at www.semi.org April 1999; to be published June 1999.

1 Purpose

1.1 To define the terms and provide a means of comparative, or relative measurement for the automated wafer prober functions: Accuracy, Repeatability and Throughput.

2 Scope

2.1 This method may be used to evaluate the performance of a single automated wafer prober, or as a means to compare many probers. The probers that this document addresses are defined as fully automated; that is, having automatic material handling, alignment and probing capabilities.

3 Limitations

3.1 This test and comparison method is not intended to represent a statistically complete methodology for measuring the performance of an automated wafer prober. Its correct use is a practical means to compare the stepping capabilities of wafer probers within a specific end user's environment.

3.2 The definitions of the terms "Repeatability" and "Accuracy" as used in this document are not in accordance with those of the National Conference of Standards Laboratories (NCSL) nor are they intended to be. They are to be used solely for the purpose of this document and have no other intended uses.

3.3 It is difficult to characterize and eliminate high temperature contributions to positional error such as probe needle 'float'. Therefore, it is strongly recommended that the same probe card be used to evaluate all of the probers being considered.

3.4 It is recommended that the probe card is verified to be in the same condition (i.e. evaluated for positional accuracy and overall functional condition) both before and after the conclusion of each test.

3.5 Bump placement on a semiconductor device is generally located ± 0.001" with respect to their nominal location. Vertical probe cards used to probe bumps have an inherent amount of needle drift. Therefore care must be exercised in using vertical probe cards on bump devices as a means of prober accuracy measurement.

4 Referenced Documents

NOTE: As listed or revised, all documents cited shall be the latest publications of adopted standards.

4.1 *SEMI Documents*

SEMI E10 — Standard for Definition and Measurement of Equipment Reliability, Availability and Maintainability (RAM)

SEMI S2 — Safety Guidelines for Semiconductor Manufacturing Equipment

5 Terminology

5.1 *3σ limit* — a statistically derived measurement of process variation. A process that allows a ± 3σ deviation will allow 2.7 parts per thousand to be outside the established bounds.

5.2 *accuracy* — the ability of an automatic wafer prober to index its chuck, and attached wafer, from an initial position to a subsequent position and make contact with a static probe tip at a nominal location on the wafer. In the context of this method, accuracy is defined as average die offset.

5.2.1 Average die offset is the perpendicular distance measured from the centerline of the die pad to a parallel line that statistically represents the scrub mark data point distribution center (see Figure 1). Each data point shown in this figure represents only the center value of accumulated scrub marks produced by operation of this method.

5.2.2 It should be noted that accuracy established by this method is characteristic of the system, which in total represents both the automated prober as well as its probe card. Finally, this method establishes two accuracy values, a value for pads along the X and Y axes of the die. These axis directions are arbitrary.

5.2.3 It should be noted that if fully automated prober set-up modes are not used for probe-needle-to-pad alignment during testing, the possibility of operator error should be considered as a variable when evaluating system accuracy.

5.3 *automatic wafer prober* — device that automatically and repeatedly aligns the die bonding pads or interconnect bumps on a semiconductor device to a set of test needles attached to a probe card.

5.4 *bonding pad* — exposed metallic contact area on a semiconductor device that is surrounded by dielectric passivation. This is the point at which a temporary interconnect is made for wafer level test, and permanent interconnect for packaging.

5.5 *bumps* — metallic elevated contact area on a semiconductor device that is used in place of a bonding pad. A die that is designed to use this type of connection is commonly called a 'flip chip' or direct chip attach.

5.6 *die* — individual semiconductor device. For the purposes of this method, the dice have not been singulated, and are still in the form of a wafer. Used interchangeably (in the context of wafer sort) with the acronym DUT (Device Under Test).

5.7 *overdrive* — distance in Z which the wafer is driven beyond a user defined initial contact point, typically 'first electrical contact'.

5.8 *overhead test* — semiconductor test method where the test head is mounted directly over the prober, with the goal of shortening the distance between the pin electronics and the probe card. The connection between the test head and the prober is generally through a device called a Prober Tester Interface (PTI)

5.9 *pin electronics* — tester hardware that creates the test signals used to challenge the DUT.

5.10 *probe card* — printed wiring board or ceramic substrate with permanently attached needles or contacts that are aligned at the time of manufacture to match the contact pattern on a Die. Common types of probe cards are:

- Blade
- Peripheral / Cantilever (AKA Epoxy Ring)
- Vertical (AKA Area Array or Cobra™)

5.11 *probe card planarity and alignment* — a user-specified position of the probe tips in 'x', 'y' and 'z'.

5.12 *probe needles* — the contact points between the probe card and the bonding pads. These are typically manufactured from one of the following materials:

- Beryllium copper
- Tungsten
- Tungsten-rhenium alloy
- Paliney

5.13 *prober tester interface (PTI)* — signal-transmitting electro-mechanical device that connects the pin cards in the tester to the probe card.

5.14 *repeatability* — Figure 1 is empirical data and represents a statistically significant sample of scrub marks. This data reveals that probe needles may not make contact consistently to the same point die to die. Recall that accuracy is defined in this method as average die offset. Thus, repeatability simply represents the three-sigma distribution value for average die offset. Repeatability will represent 99.7% or a three-sigma distribution value for the accumulated offset data points obtained through use of this method.

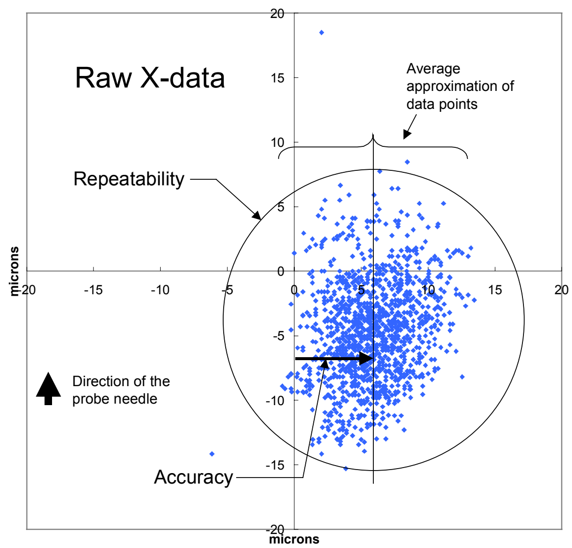

Figure 1

Raw X-Data

5.14.1 The X-Y plotted centroids of these scrub marks will be found to form a "cloud" of points, densest in the center, and thinning out towards the edges.

5.14.2 Repeatability is the radius of that cloud or "cluster" of probe marks, as defined by the 3 σ or other user defined limit of that cloud. The error in the placement of the center of that cloud, relative to its nominal target, is defined as the automatic wafer prober's "Accuracy". (See Figure 1)

5.15 *set point* — the value to which a control system's input device has been set, as opposed to the actual value to which the control system has driven the controlled variable. For example, the input setting to the wafer chuck temperature controller, as opposed to the actual, independently measured temperature of the wafer chuck.

5.16 *soak time* — time between a piece of equipment's reaching the set point temperature and use of that piece of equipment.

5.17 *scrub mark* — mark left by the probe in the bonding pad or bump after the probe card has touched down on the wafer.

5.18 *temperature testing* — testing of devices at a controlled temperature level other than ambient.

5.19 *test* — one complete run-through of the data collection portion of this document on one automated wafer prober.

5.20 *tester* — specialized computer controlled system designed to test integrated circuits.

5.21 *prober communications protocol (see Section 9.6)* — means of transmitting data between the tester and the prober. Common methods are:

- TTL
- RS-232c
- GPIB

5.22 *test head* — package of electronics (part of the Tester) which interacts both electrically and mechanically with the probe card, typically through the Prober Tester Interface (PTI).

5.23 *throughput* — rate at which die can be cycled, by the automatic wafer prober, for the purpose of being tested. It is inherent in the functionality of an automatic wafer prober (or any other motorized positioning device) that accuracy, repeatability and throughput are intimately and inseparably related.

5.24 *touch down* — contact between the probe card and the wafer. This user may choose to define this as either first electrical or first mechanical contact.

5.25 *wafer* — semiconductor substrate upon which multiple die are fabricated.

5.26 *wafer boat or wafer cassette* — carrier for multiple wafers.

5.27 *wafer chuck* — platform within an automatic wafer prober that supports and transports the wafer. The chuck may contain the means for controlled temperature testing.

5.28 *x, y, z and* θ — motions relative to the center of the Probe Card when standing in front of the Prober:

- Motion to the right is motion in the positive X-direction.
- Motion towards the back of the prober is motion in the positive Y-direction.
- Motion away from the floor is the positive Z-direction.
- Motion revolving around a Z-axis passing through the center of the probe card is θ-motion. Motion in the counter-clockwise direction when facing down from above the prober is motion in the positive θ-direction.

5.29 *z-clearance* — distance between the user defined initial contact point and the top surface of the wafer during that portion of the wafer prober’s cycle when the wafer chuck is moving the wafer between DUTs.

6 Summary of Method

6.1 *Objective* – A SEMI Probe Standards Task Force has defined this method. That task force consisted of members from semiconductor wafer probe system users and wafer probe system suppliers. This method, in part a guide to collection of data, is aimed at a specific set of wafer probe system parameters: accuracy, repeatability and throughput. This method is a tool that creates comparative data. That data will act as a criterion by which multiple wafer probe systems can be judged competitively.

6.2 *Probe System Accuracy and Throughput* – A wafer probe system will have needle placement error due to the probe system electromechanical systems, and additional needle placement error due to the probe card physical alignment of the needles. The degree of accuracy to which the probe system can place the chuck, the effectiveness of the probe system's bond pad to needle alignment, the physical alignment of the probe card needles in their X and Y plane, and the probe system's vision resolution and accuracy (x microns of distance per pixel) will be the factors that influence a probe system's overall placement performance.

6.2.1 Probe system comparative accuracy and repeatability are established in this method using probe mark data acquired manually with a vision system or, if available, through use of an automated probe mark data analysis system. Acquired data is analyzed with the Probe Mark Data Analysis algorithm contained in this method.

6.2.1.1 The intention of this data collection exercise is not to make a deterministic conclusion establishing a probe system’s accuracy. Data analysis results are only meaningful in the context of a comparative analysis of multiple probe systems.

6.2.2 Probe system throughput is best determined using time measurements made using a stopwatch. Other approaches can be applied, such as:

- the time stamp and log file (if available) on the probe system under evaluation.
- time tracking within the device test program employed for testing the prober.

6.2.3 Any of these approaches is viable for measuring time intervals during probe system operation. That data is to be entered into the data collection table as part of the application of this method.

6.2.4 The algorithm collects data from 9 wafers out of a lot of 10. Three setups are performed using 3 wafers per setup. All dice will be probed, but data will be taken only on twelve of the die on each wafer. Twenty-four pads on each die are evaluated (see Figure 4). Overall, 2592 die pads are analyzed in a lot.

6.2.5 When all the data is collected and analyzed, each probe system will have an average die offset value. This will be a comparative representation of accuracy consisting of average offsets for all evaluated die. This comparative representation of accuracy is a measure of how accurate the probe systems place the chuck, and thus the probe needles, to the center point on the die pads, consistent with normal operation of the probe systems.

6.2.6 In general, when the probe marks are viewed across all dice, there will be a data spread, or distribution of error points for each wafer. Repeatability is the $\pm 3\sigma$ variation of all die offsets, identified in this method as the 3σ calculation of *Normalized Die Offset*.

6.3 *Probe Card Issues* – Probe card construction variability and probe card usage at temperatures other than ambient are important considerations. The following sources of error should be kept in mind:

- In a hot chuck environment the probe card and needles will experience a high percentage of the elevated chuck temperature. The material selection for the probe card will determine how it expands and contracts due to the temperatures applied. Probe systems can be equipped with programmable preheat (soak) times. Longer preheat times will reduce probe card variability while decreasing throughput.
- Needle construction can result in excessive error due to bending of the needles when excessive probe system z-stage overdrive is applied. The number of needles and the selection of needle technology, i.e., cantilever versus vertical, is another variable, having a noticeable influence on measurement results.
- Since each user of this method is not confined to a standard for probe card construction, the user of this method is advised to choose a probe card and vendor with good integrity, and to use that same probe card when evaluating multiple probe systems. The assertion here is that the same probe card used to evaluate multiple systems will react in a repeatable manner under varying environmental conditions. This assumes there is no excessive probe card needle wear during the multiple evaluations, and that needle alignment is verified or achieved before each execution of the procedure.

6.3.1 Probe mark scrub length can vary due to several factors including:

- variations in the flatness of the chuck and stage travel that are not compensated by the z-sensor mapping algorithms
- by hard spots in the aluminum pads, or
- by variations in probe tip geometry, etc.

6.3.2 To minimize the impact of this variation in the probe mark analysis algorithm, use only scrub mark location data that is taken normal to the direction of scrub. Distances measured normal to the orientation of the scrub mark are generally accepted to be significantly more stable than that which is taken parallel to the scrub mark (see Figure 2).

6.3.3 In summary, the probe card itself can be a limiting factor when making needle placement accuracy measurements, especially at varying environmental conditions. Material selection, vendor to vendor variation, construction of a probe card (blade, epoxy ring, vertical, etc.), especially with varying environmental conditions, will create inconsistent analysis results, unless care is taken with the application of this method. The precautions discussed here are meant to promote consistent and accurate evaluation results for this method.

6.3.4 Nevertheless, the precautions mentioned here could ALSO be an important basis for using this method. As an example, a probe card is typically designed for XY positional placement and planarity, and is expected to meet customer specification requirements in normal operation at room temperatures. This method could serve as a means of establishing numerical results that represents the effects that temperature or probe card construction variability have on probe card specification requirements.

6.4 *The PMA Algorithm* – A best-fit rectangle can be drawn around the scrub mark and the passivation opening for each pad, reference Figure 3.

NOTE: Applying a best-fit rectangle around the passivation opening may prove difficult for certain vision systems. Application of the best-fit rectangle around the die pad metal is an acceptable alternative. The center position of the best-fit rectangle around the scrub mark will represent the center of the scrub mark. The center of the die pad is the center of the best—fit rectangle around the passivation opening. The distance between the two centers is the pad offset. Pad offset is computed from the four values *left*, *right*, *top*, and *bottom*, reference Figure 2.

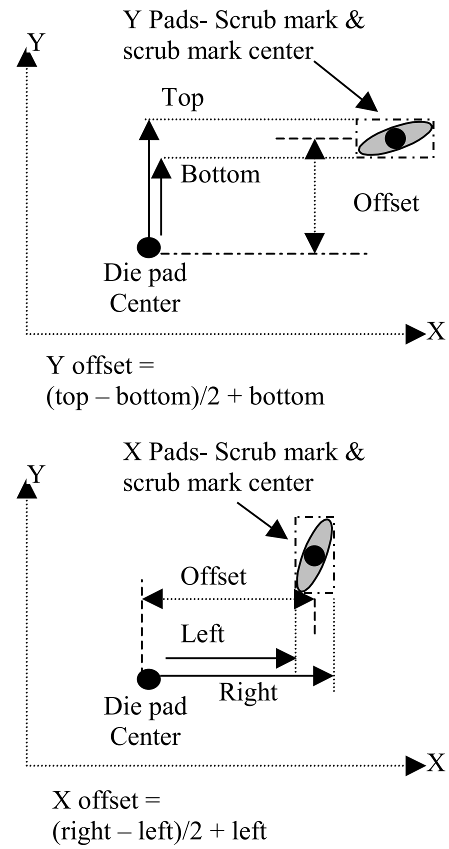

Figure 2

X and Y Offset

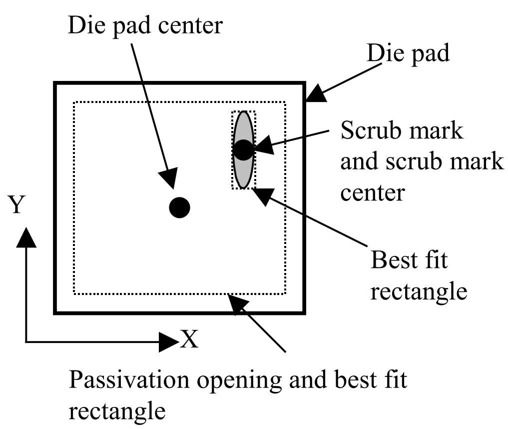

Figure 3

Scrub Mark Analysis

6.4.1 Vision system measurements will be made establishing offset distances from the die pad center to the scrub mark. The stability of the measurement is greater when made perpendicular to the direction of the scrub mark. This will establish X and Y offsets via measurement of offsets for pads in the X and Y plane of the die.

6.4.2 Once the offsets are established, a two-step procedure will manipulate 1296 X and 1296 Y offset values. The end result of the algorithm will be a relative measure of the total probe system accuracy and repeatability for the pads analyzed. Figure 5 represents a visual summary of the method.

6.5 *Considerations of Scale* — When evaluating the suitability of a particular probe system to probe a particular size of bond pad, or to probe accurately at a particular pad-to-pad pitch, a good rule of thumb is that the prober's positional accuracy, as stated in its specifications, should be 1/10 that of the scale of the features to be probed. For example, if the probe system being evaluated has an overall placement accuracy of 5µm, it would be inappropriate to analyze wafers using this method and this probe system for dice that have pads less than 50 µm square (this would be less than 10x).

6.5.1 Regardless, when this method is used for evaluation of multiple systems, it is essential that die and bond pad size/pitch consistency be maintained from evaluation to evaluation if the results are to be meaningful.

6.5.2 The same 10× rule applies to the vision system or automated Probe Mark Analysis system employed to make the pad offset measurements. These systems should have a pixel resolution that is at least 10× finer than the die pad dimensions associated with the scrub marks being measured.

6.6 *Conclusion* — It is assumed that the user of this method has a wafer probe system or systems, or is planning to make a selection from the various systems available in the market place, and requires objective comparative analysis for accuracy, repeatability and throughput.

6.6.1 It should be clear that this method employs a three-step process of probing, probe mark data collection, and data analysis.

6.6.2 When probing, every die on each of the ten wafers is to be "tested" and probed. Of those ten wafers, the last nine with 12 die per wafer will be used for scrub mark data collection. At least 24 pads per die will be used for the analysis. The first wafer is meant only to allow stabilization for the probe system and its probe card.

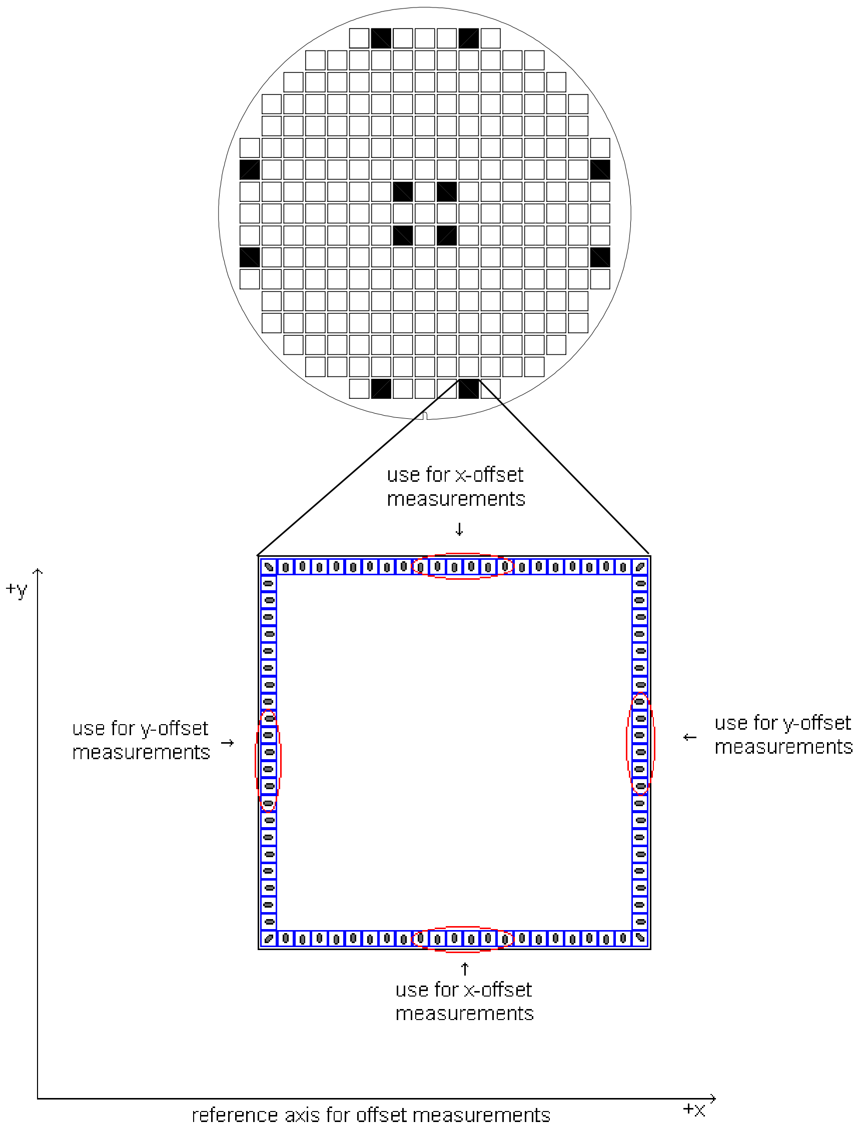

Figure 4

Recommended Dice and Pads to be used for Data Collection

6.6.3 It is important that the wafers used with this method are probed only once, or else multiple scrub marks may be difficult for the measurement system to deal with and will most likely influence the analysis results. This method assumes the wafer is ideal, having no die skew due to wafer process anomalies.

NOTE: It is possible that a not so perfect probe tip to pad alignment (PTTPA) may create misleading results for this method. It is recommended that PTTPA be done on die located at the edge of the wafer, as shown in Figure 4. This is opposed to having PTTPA done on die in the center of the wafer. An offset error incurred in the context of a PTTPA done in the center may result in an incremental and continuing error as testing moves across the wafer. With this method that error may be averaged-out.

6.6.4 Probe system index time is device and probe system dependent. Probe system index time is determined by acceleration, maximum achievable velocity, and distance traveled die to die by the chuck. Thus, the device type chosen for use with this method should be representative of typical die size if meaningful index time and throughput data are to be gathered.

6.6.5 If the results of this method turn out to be unfavorable, the user has the option of applying a more detailed, enhanced data analysis application of this method. That application is contained in Appendix 1. The enhanced method uses the same data, but it requires more manipulation of the data during data analysis. The detail contained in the enhanced algorithm will provide the user with greater insight as to the cause of unfavorable results related to the probe system under evaluation. A summary of the enhanced method is shown in Figure 6.

6.7 *Alternatives* — What has been left undefined to this point is availability of an automated approach to data collection per the requirements of this method. Regardless, data collection can be manually accomplished. The manual process is laborious and requires a video measuring system to make offset measurements on the die pads, and a spreadsheet to analyze the resulting data.

6.7.1 If manual operation is not desirable or practical, automated Probe Mark Analysis Systems do exist in the market place as an item to be purchased. Providers are also available to accept probed wafers and execute probe mark analysis under contract as a service.

NOTE: *A Final Note to the User of This Method* — This method provides sufficient data for sophisticated analysis of probe system performance across die-to-die, wafer-to-wafer, and setup-to-setup. It also provides a simple metric. It is easy to make comparisons with simple "single number" metrics, but that has the potential for oversight, distortion and subsequent inappropriate comparisons. The test engineer, working with the probe system supplier, must be the ultimate judge of the applicability of this method and the correct interpretation of the results.

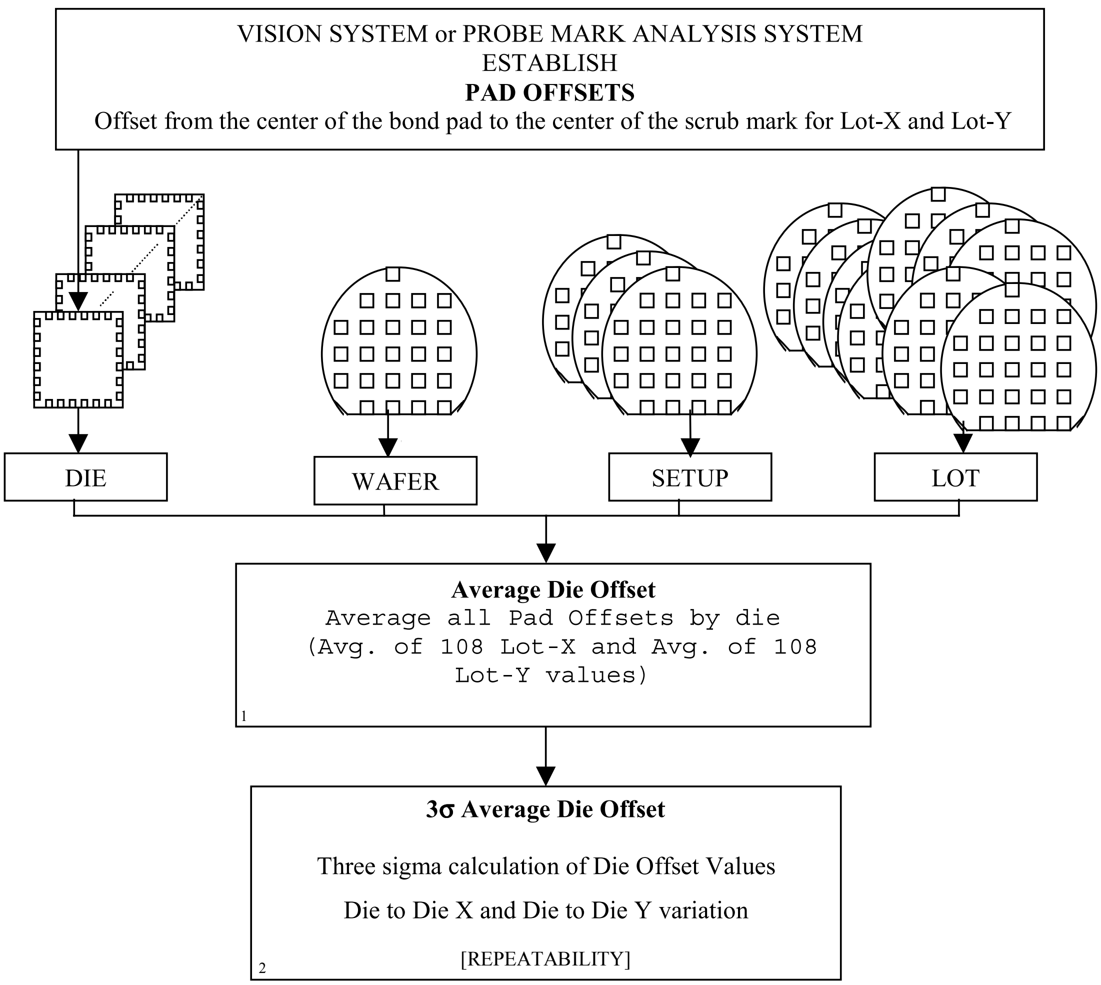

Figure 5

Pad Offset and Two-Step Analysis Algorithm for Determining Probe System Error

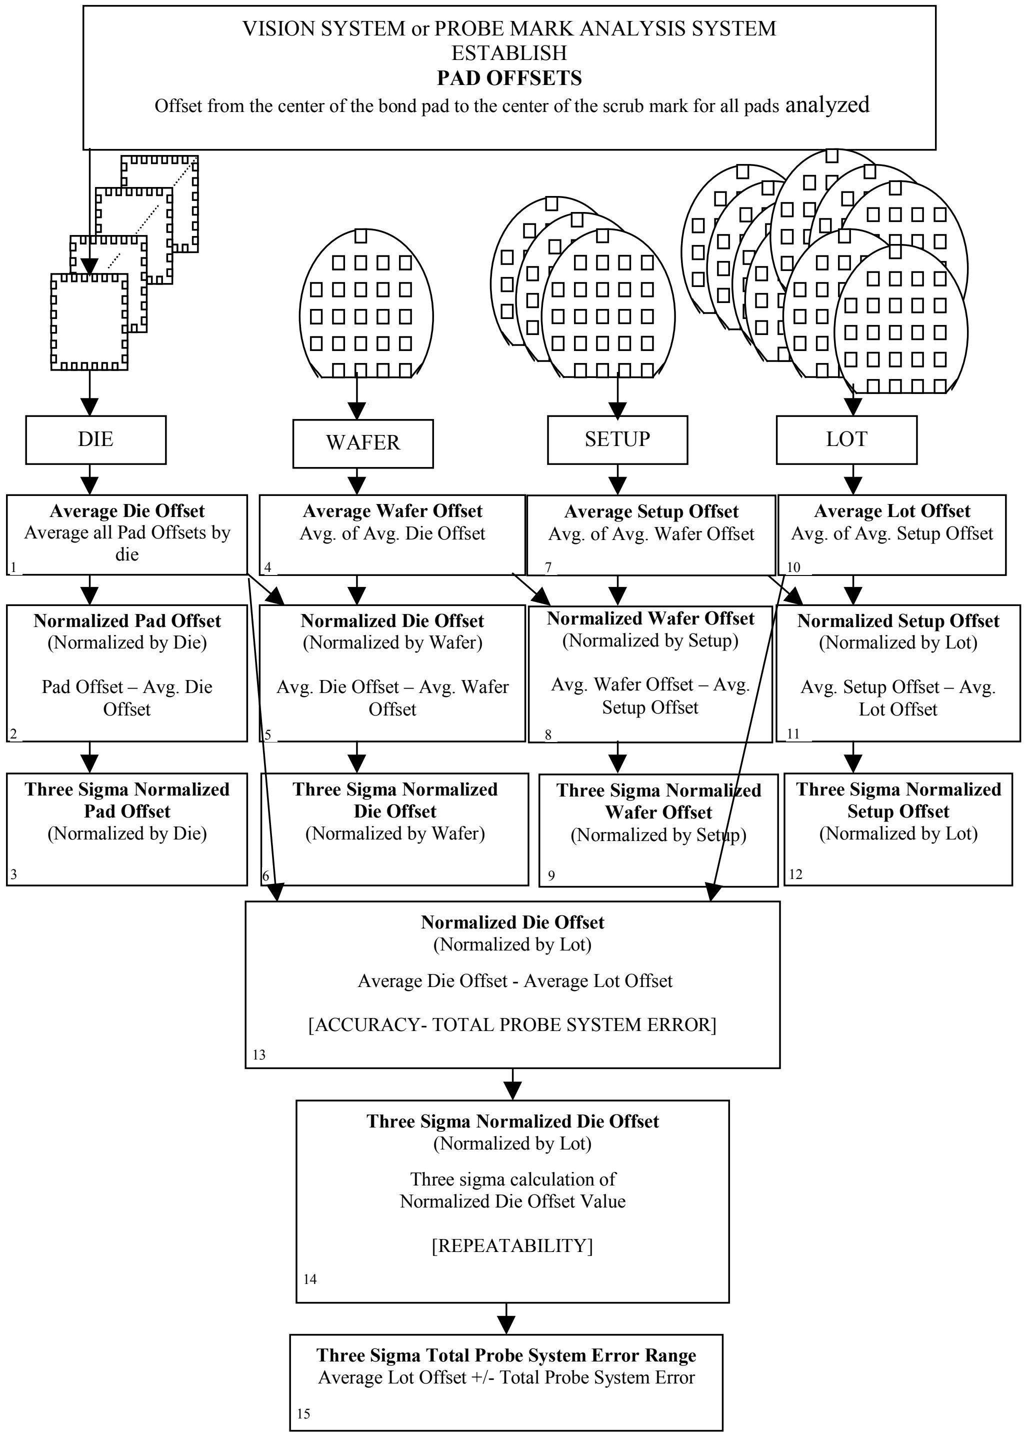

Figure 6

Pad Offsets and 15-Step Analysis Algorithm for Determining Probe System Error

7 Required Hardware Checklist (see Figure 7)

- ❑ Wafer prober (if the test plan includes either hot or cold chuck testing, the prober must be appropriately equipped).
- ❑ A planarized and aligned probe card which matches the selected wafers, accompanied by a metrology tool printout of the 'x', 'y' and 'z' positions of all of the probe tips to be used for probe mark analysis. Note: The probe card should be measured for alignment, but not "tweaked", immediately prior to and after the conclusion of each subsequent test.
- ❑ Untested wafers
- ❑ A special "test program" with a fixed "test" time.
- ❑ Tester or PC that will run the "test program". If a PC is used to simulate the tester, it must be equipped with the appropriate hardware for communication with the wafer prober.
- ❑ A stopwatch, with 0.1 second resolution. The stopwatch is to have "split" capability.

  Note that the user of this method may choose at their discretion to utilize any other time stamp logging technology at their disposal, so long as the computational overhead of this logging has no effect upon the throughput of the prober.

8 Requirements (see Figure 7)

8.1 *Qualified Prober* — Before initiating the test process, the wafer prober is to be certified by a representative of the prober manufacturer to be fully operational.

8.2 *Qualified Personnel* — The individual running the wafer prober for the test procedure must be certified or otherwise qualified to operate the prober being tested.

9 Test conditions (see Figure 7)

9.1 *Test Time* — a fixed "device test time" will be used during these tests. The recommended value for this test time is 1.0 seconds.

9.2 *Accuracy and Repeatability vs. Throughput* — The person or manufacturer running this test may make a choice (or choices) as to how they elect to balance accuracy and repeatability with throughput, but all three tests must be run simultaneously. This will generate a set of numbers defining a particular prober's accuracy and repeatability at a given throughput (or a throughput at a given accuracy and repeatability). All adjustments to the prober are to be made using standard, end-user-adjustable settings, and all prober settings associated with a particular throughput / accuracy and repeatability combination are to be included in the final report.

9.3 *Temperature* — This test can be conducted at any temperature, however, numerous variable can distort the results if run at a temperature other than ambient, i.e. probe tip drift due to an increase or decrease in temperature.

- *Cautionary Note: If the tests are performed at temperatures other than ambient, the user must use the same probe card and wafer type for all tests across all test platforms to ensure uniformity of results.*

9.4 *Probe Card Type* — All types of probe cards (blade, peripheral / cantilever or vertical) may be used, so long as they leave a visible scrub mark.

- *Cautionary note: Some vertical probe cards exhibit an inherent amount of 'x' - 'y' needle drift. The user should verify the intrinsic repeatability of the probe card before using it to characterize the prober.*

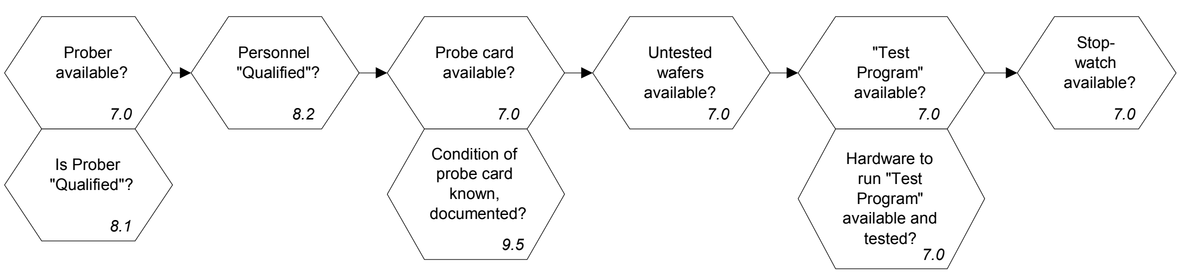

Figure 7

Preparation

9.5 *Probe Card Condition* — a metrology tool printout verifying the 'x', 'y' and 'z' position of each probe is within the users specification must accompany the probe card.

9.6 *Tester – Prober Communications* — The type of communications method used between the prober and the tester is left up to the user of this test method. Because communication overhead varies with protocol, the same hardware and "test program" (modified as necessary to communicate to the prober under test) must be used for all tests.

9.7 *Presence of the PTI* — During the test, the probe card must have loading similar to that applied by the normal "in use" application such as a Probe Test Interface (PTI) or Direct Docking Pogo Stack. The force exerted on the probe card by the PTI will stabilize the probe card, improving the repeatability of the data collected.

9.8 *Wafer Cassette* — For the purposes of these tests, a cassette of wafers is defined as containing ten wafers. Ensure the wafers are placed in the same slots for each test.

10 Test Procedure (see Figures 8 and 9)

10.1 Load wafer cassette

10.2 Install probe card

10.3 Set probe mode to serpentine, set all other necessary prober parameters. NOTE THAT ALL DIE ON ALL WAFERS ARE TO BE "TESTED", NOT JUST THE 12 DIE FROM WHICH PROBE MARK DATA WILL BE ANALYZED.

10.4 Note all applicable parameters (see chart below)

10.5 If temperature testing, soak for a user-defined time (consistent with the user's test methodologies) that is equal on all corresponding tests on all probers being evaluated.

10.6 Start probing process and stopwatch simultaneously.

10.7 The "test program" must perform automatic alignment of the probe card to the wafer prior to wafer #'s 1, 2, 5, and 8.

NOTE: While not required, it is recommended that the PTI and Probe Card be removed and re-installed prior to each of the automatic alignment steps to simulate whatever locational error might be induced by manipulation of the interface and the probe card.

10.8 Record times of individual events (utilizing the stopwatch's "split" function) on the supplied chart or a similar form.

10.9 When the last wafer is finished and has been returned to wafer cassette, stop the stopwatch.

10.10 Collect the probe mark offset data from wafers.

10.11 Calculate Normalized (by lot) Die Offset [Accuracy] and 3σ of Normalized (by lot) Die Offset [Repeatability]:

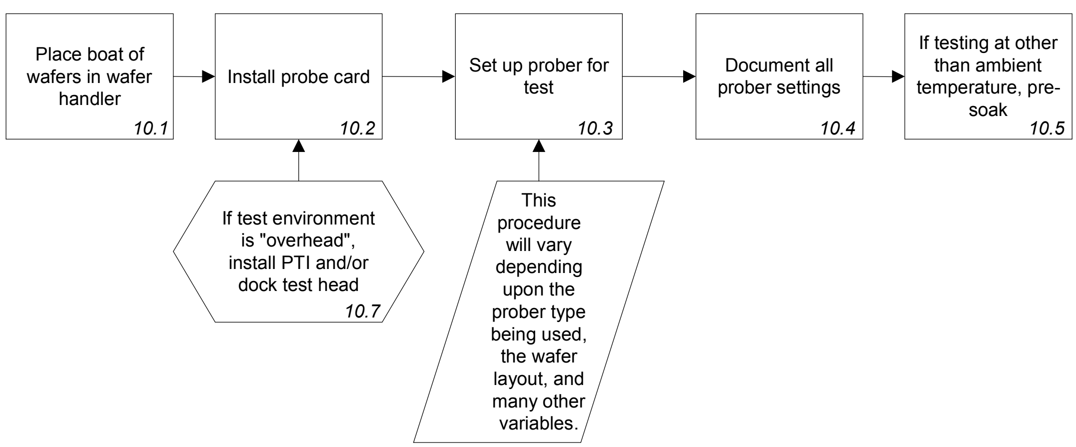

Figure 8

Setup

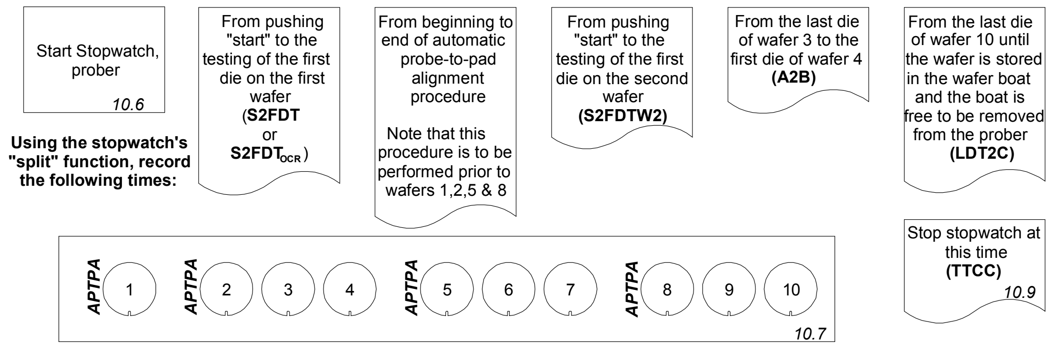

Figure 9

Timing Procedure

11 Introduction

11.1 The Probe Mark Analysis System recognizes the edge of the bond pad passivation opening and the probe mark, draws a best-fit rectangle around the probe mark and passivation opening, and returns the four distances, Left, Right, Bottom and Top to a text file. The center position of the best-fit rectangle can be used to represent the center of the scrub mark. An offset of this center of scrub mark from the center of the bond pad can be calculated as follows:

$$\begin{aligned} PadXoffset &= (Left - Right)/2 \\ PadYoffset &= (Bottom - Top)/2 \end{aligned} \qquad (1)$$

The variation of this offset from pad to pad, die to die, wafer to wafer and setup to setup captures most of the process variations.

11.2 *PMA Data Analysis*

11.2.1 We will use a sampling scheme of 9 wafers per lot, (3 setups per lot, 3 wafers per setup), 12 dies per wafer and 24 pads per die as an example for discussing the data analysis algorithm. The first step of doing data analysis is to obtain the offsets for all the pads that have been sampled using Eqn.(1). This means that the offsets

$$\text{[PadXoffset]}\ xoff_{loti,setj,wafk,diel,padm},\ \text{[PadYoffset]}\ yoff_{loti,setj,wafk,diel,padm} \qquad (2)$$

for a pad m on die l, wafer k, under setup j in lot i are known.

Step 1

Calculate ***Average Die Offset*** for the lot [LOTX or LOTY] (3)

$$\begin{aligned} xoff_{loti,setj,wafk,diel} &= \frac{1}{12}\sum_{m=1}^{12} xoff_{loti,setj,wafk,diel,padm} \\ yoff_{loti,setj,wafk,diel} &= \frac{1}{12}\sum_{m=1}^{12} yoff_{loti,setj,wafk,diel,padm} \end{aligned} \qquad (3)$$

Step 2

Calculate D-D-X or D-D-Y = 3σ of ***Average Die Offset*** **[LOTX] and [LOTY]**(3)

These die offsets are again treated on the equal basis. A 3σ value is calculated and becomes our Die-to-Die Variation (D-D-X, D-D-Y) for the entire lot.

LOTX + D-D-X, LOTX - D-D-X = Total Prober X-Error Range (3σ)
LOTY + D-D-Y, LOTY - D-D-Y = Total Prober Y-Error Range (3σ)

Suggested Graphs for X-Offset and Y-Offset (see Appendix 1 for examples):

X-Offset	**Y-Offset**
LOTX + D-D-X	LOTY + D-D-Y
LOTX	LOTY
LOTX - D-D-X	LOTY - D-D-Y
Average Die X-Offset (3)	Average Die Y-Offset (3)

12 Data Collection Table

12.1 The following data are to be recorded about the test environment:

Title	*Description*	*Values*	
Tester - Prober Interface	Installed (Yes/No)		
	If installed, Total Pogo® pin force (nominal, calculated)		kg
			pounds
Tester	Present [docked] (Yes/No)		
	If present, state manufacturer and model		
Wafer	Nominal Die Size (Small, Medium or Large)		
Probe Card	Needle count		
	Nominal force per needle		grams
			ounces
	Diameter of needle tip		microns
			mils
	Needle pitch (within a single row or column)		microns
			mils
	Number of needle tiers		
	Size of needle array in the X direction (left-to-right when facing prober (from the operator position))		mm
			inches
	Size of needle array in the Y direction (away and towards the operator relative to the center of the probe card)		mm
			inches
	Diameter of probe card		mm
			inches
Test Temperature	Set point / Temperature of chuck during test		ºC
			ºF
	Soak time, probe card (if test temperature is other than ambient)		minutes
	Soak time, prober (if other than ambient)		minutes

Title	Description	Values	
DUT spacing	X-direction		microns
			mils
	Y-direction		microns
			mils
Z clearance			microns
			mils
Overdrive			microns
			mils
Tester-Prober communications method			
OCR Variables	OCR on? (Y/N)		
	SEMI standard font? (Y/N)		
	# of retries allowed		

Definitions for formulae:

Variable	Description	Values	
DPW	Die Per Wafer		
TT	Test Time (minimum value of 1.0 seconds)		seconds

Data Collected	Description	Values	
A2B	Last die (Wafer A) to first die (Wafer B) time		seconds
S2FDT	Time from pushing "Start" to First Die Test with OCR turned off		seconds
$S2FDT_{OCR}$	Time from pushing "Start" to First Die Test with OCR turned on		seconds
S2FDTW2	Time from pushing “Start” to First Die Test, Wafer #2		seconds
LDT2C	Time from end of Last Die Test to Cassette free to remove from prober		seconds
TTCT	Total Time to Complete Test		seconds
TTAA	Time To Auto-Align the probe needles with the die bonding pads		seconds

$$D2D = \frac{TTCT - (TT \times DPW \times 9) - (A2B \times 8) - S2FDTW2 - LDT2C - (TTAA \times 3)}{DPW \times 9}$$

Calculated Results	Values	
D2D		seconds

APPENDIX 1
CALCULATION OF NORMALIZED DIE OFFSET AND TOTAL PROBER ERROR RANGE (3σ)

A1-1 Probe Mark Data Analysis Algorithm:

A1-1.1 *Introduction*

A1-1.1.1 The Probe Mark Analysis system recognizes the edge of the bond pad passivation opening and the probe mark, draws a best-fit rectangle around the probe mark and passivation opening, and returns the four distances, Left, Right, Bottom and Top to a text file. The center position of the best-fit rectangle can be used to represent the center of the scrub mark. An offset of this center of scrub mark from the center of the bond pad can be calculated as follows:

$$PadXoffset = (Left - Right)/2$$
$$PadYoffset = (Bottom - Top)/2 \qquad (1)$$

A1-1.1.2 The variation of this offset from pad to pad, die to die, wafer to wafer and setup to setup captures most of the process variations.

A1-1.2 *PMA Data Analysis*

A1-1.2.1 We will use a sampling scheme of 9 wafers per lot, (3 setups per lot, 3 wafers per setup), 12 die per wafer and 24 pads per die. The first step of doing data analysis is to obtain the offsets for all the pads that have been sampled using Eqn.(1). This means that the offsets

$$\text{[PadXoffset]}\ xoff_{loti,setj,wafk,diel,padm},\ \text{[PadYoffset]}\ yoff_{loti,setj,wafk,diel,padm} \qquad (2)$$

for a pad m on die l, wafer k, under setup j in lot i are known.

A1-1.3 Step 1 — Calculate Average Die Offset (3)

$$xoff_{loti,setj,wafk,diel} = \frac{1}{12}\sum_{m=1}^{12} xoff_{loti,setj,wafk,diel,padm}$$
$$yoff_{loti,setj,wafk,diel} = \frac{1}{12}\sum_{m=1}^{12} yoff_{loti,setj,wafk,diel,padm} \qquad (3)$$

A1-1.3.1 *Discussion of Average Die Offset*

A1-1.3.1.1 Based on the sample described, there will be an Average Die Offset-X and Average Die Offset Y for each of the 108 die sampled. This value is probably the most descriptive, especially when graphed (see example graphs). Both X and Y-graphs will most likely resemble a sine wave. This is due to wafer rotation. As you serpentine across the wafer there will be a slight offset from die to die. Since the selected sample dice are in the center and around the edges of the wafer, you can see the progression of the offset as you move farther from the center of the wafer. The X and Y graphs are usually about 90º out of phase.

A1-1.3.1.2 Other qualitative information can also be gathered by visually looking at the graphs of this data. One can determine whether the accuracy is varying wafer to wafer (each set of 12 data points is a wafer) or set-up to set-up (each set of 36 data points is a set-up) or just drifting over time. Drift over time is sometimes caused by temperature stabilization issues within the prober mechanism. Subsequent steps will quantify how much variability is caused by each.

A1-1.4 Step 2 — Calculate Normalized (by die) Pad Offset (4) = (2) - Average Die Offset (3)

$$xnorm_{loti,setj,wafk,diel,padm} = xoff_{loti,setj,wafk,diel,padm} - xoff_{loti,setj,wafk,diel}$$
$$ynorm_{loti,setj,wafk,diel,padm} = yoff_{loti,setj,wafk,diel,padm} - yoff_{loti,setj,wafk,diel} \quad (4)$$

A1-1.4.1 *Discussion of Normalized (by die) Pad Offset*

A1-1.4.1.1 This step helps to quantify how much error is caused by the prober vs. the probe card. The probe card usually does NOT impact average offset of a die, just the variability within a die. In this equation, we subtract the average die offset (presumed prober error) from each pad in that die. This data is then used for the next step.

A1-1.5 Step 3 — Calculate P-P-X or P-P-Y = 3σ of Normalized (by die) Pad Offset (4).

A1-1.5.1 All the normalized pad offsets in the same lot (no matter on which die, on which wafer the pad resides) are treated on an equal basis. In our example, a total of 2592 pads are sampled in a lot. All 1296 x-direction and 1296 y-direction pads of ***Normalized (by die) Pad Offset*** will be used to calculate a 3σ variation which is called Pad-to-Pad variation (P-P-X and P-P-Y).

A1-1.5.2 *Discussion of P-P-X or P-P-Y (Pad-to-Pad Variation in the X-direction or Pad-to-Pad-Variation in the Y-direction)*

A1-1.5.2.1 These values describe how much variability there is within all the pads in the lot. This value is frequently attributed to probe tip variation in X, Y, and Z. Although probe tips do change and wear over time, their unloaded position usually does not change dramatically within one lot. This value does not help tremendously in describing prober accuracy nor should it be used for any sort of probecard metrology. However, be sure to perform a mental reality check to verify that it is somewhere near (within an order of magnitude of) your probe card X/Y probe needle position specification.

A1-1.6 Step 4 — Calculate Average Wafer Offset (5) = average of Average Die Offset (3).

$$xoff_{loti,setj,wafk} = \frac{1}{12}\sum_{l=1}^{12} xoff_{loti,setj,wafk,diel}$$
$$yoff_{loti,setj,wafk} = \frac{1}{12}\sum_{l=1}^{12} yoff_{loti,setj,wafk,diel} \quad (5)$$

A1-1.6.1 *Discussion of Average Wafer Offset*

A1-1.6.1.1 This equation will result in nine values for Average Wafer Offset-X and nine for Average Wafer Offset-Y. These numbers could also be graphed to look for trends from wafer to wafer (this is not included on the example graphs). If there is a consistent trend in one direction possible causes are:

- wafer loading error
- cumulative stepping error, and
- temperature stability errors

A1-1.7 Step 5 — Calculate Normalized (by wafer) Die Offset (6) = Average Die Offset (3) - Average Wafer Offset (5)

$$xnorm_{loti,setj,wafk,diel} = xoff_{loti,setj,wafk,diel} - xoff_{loti,setj,wafk}$$
$$ynorm_{loti,setj,wafk,diel} = yoff_{loti,setj,wafk,diel} - yoff_{loti,setj,wafk} \qquad (6)$$

A1-1.7.1 *Discussion of Normalized (by wafer) Die Offset*

A1-1.7.1.1 This normalization step is a precursor to calculating a 3σ variation value. To calculate the true Die-to-Die variation, any wafer-to-wafer induced error is subtracted out from the by-die-data. This data is used in the next step.

A1-1.8 Step 6 — Calculate D-D-X or D-D-Y = 3σ of Normalized (by wafer) Die Offset (6)

A1-1.8.1 These normalized die offsets are again treated on the equal basis. A 3σ value is calculated and becomes our Die-to-Die Variation (D-D-X, D-D-Y).

A1-1.8.2 *Discussion of D-D-X or D-D-Y (Die-to-Die 3σ variation in the X-direction, Die-to-Die 3σ variation in the Y-direction)*

A1-1.8.2.1 This equation will result in the 3σ variation of the average die offsets from Die-to-Die in both X- and Y-directions. If this number is very large, there should be concern about the repeatability of the prober.

A1-1.9 Step 7 — Calculate Average Setup Offset (7)

$$xoff_{loti,setj} = \frac{1}{3}\sum_{k=1}^{3} xoff_{loti,setj,wafk}$$
$$yoff_{loti,setj} = \frac{1}{3}\sum_{k=1}^{3} yoff_{loti,setj,wafk} \qquad (7)$$

A1-1.9.1 *Discussion of Average Setup Offset*

A1-1.9.1.1 These equations will produce six values, three for Average- (by Setup) Offset-in-the-X-direction and three for Average- (by Setup) Offset-in-the-Y-direction. These values describe the average offset of all of the die “tested” with a particular setup.

A1-1.10 Step 8 — Calculate a Normalized (by setup) Wafer Offset (8) = Average Wafer Offset (5) - Average Setup Offset (7).

$$xnorm_{loti,setj,wafk} = xoff_{loti,setj,wafk} - xoff_{loti,setj}$$
$$ynorm_{loti,setj,wafk} = yoff_{loti,setj,wafk} - yoff_{loti,setj} \qquad (8)$$

A1-1.10.1 *Discussion of Normalized (by setup) Wafer Offset*

A1-1.10.1.1 A normalizing step to help calculate the true wafer-to-wafer variation.

A1-1.11 Step 9 — Calculate W-W-X or W-W-Y = 3σ of Normalized (by setup) Wafer Offset (8).

A1-1.11.1 A 3σ variation will be calculated based on the normalized wafer offset and will be cited as the Wafer-to-Wafer variation (W-W-X, W-W-Y).

A1-1.11.2 *Discusssion of W-W-X or W-W-Y (Wafer-to-Wafer variation in the X-direction, Wafer-to-Wafer variation in the Y-direction)*

A1-1.11.2.1 This equation will produce a value for the 3σ variation from Wafer-to-Wafer in the X and Y directions. If this number were large, it would tend to indicate that the prober does not behave repeatably from wafer-to-wafer. Possible causes are:

- loading problems
- temperature stability issues, and
- wafer rotation issues

A1-1.12 Step 10 — Calculate Average Lot Offset (9) = average of Average Setup Offset (7).

$$LOTX = \frac{1}{3}\sum_{j=1}^{3} xoff_{loti,setj}$$
$$LOTY = \frac{1}{3}\sum_{j=1}^{3} yoff_{loti,setj} \qquad (9)$$

A1-1.12.1 *Discussion of Average Lot Offset (LOTX or LOTY)*

A1-1.12.1.1 This will be one of the values added to the graph. This is simply the average of all of the average die offsets in the X-direction and all of the average die offsets in the Y-direction. If one needed to pick a single number in X and Y to describe the accuracy of the prober – this is the one. This can be very misleading though – what this number really tells you is what value the distribution is centered around. Refer to the graph to get a visual sense of this data.

A1-1.13 Step 11 — Calculate Normalized (by lot) Setup Offset (10) = Average Setup Offset (7) - Average Lot Offset (9)

$$xnorm_{loti,setj} = xoff_{loti,setj} - LOTX$$
$$ynorm_{loti,setj} = yoff_{loti,setj} - LOTY \qquad (10)$$

A1-1.13.1 *Discussion of Normalized (by lot) Setup Offset*

A1-1.13.1.1 This is another normalization step used to calculate the true setup-to-setup error in X and Y.

A1-1.14 Step 12 — Calculate S-S-X or S-S-Y = 3σ of Normalized (by lot) Setup Offset (10).

A1-1.14.1 A 3σ variation will be calculated based on the normalized setup offset and will be cited as the Setup-to-Setup variation (S-S-X, S-S-Y).

A1-1.14.2 *Discussion of S-S-X or S-S-Y (Setup-to-Setup variability in the X-direction, Setup-to-Setup variability in the Y-direction)*

A1-1.14.2.1 These two values describe how much variability there is between setups.

A1-1.15 Step 13 — Calculate Normalized (by lot) Die Offset (11) = Average Die Offset (3) - Average Lot Offset (9) [Accuracy]

$$xn_{loti,setj,wafk,diel} = xoff_{loti,setj,wafk,diel} - LOTX$$
$$yn_{loti,setj,wafk,diel} = yoff_{loti,setj,wafk,diel} - LOTY \qquad (11)$$

A1-1.15.1 *Discussion of Normalized (by lot) Die Offset*

A1-1.15.1.1 This step is useful if you need to compare the variation between several different lots. It is not completely necessary for the next step, since subtracting a constant from a string of numbers does not change the 3σ variation, only the center point.

A1-1.16 Step 14 — Calculate TTLX or TTLY = 3σ of Normalized (by lot) Die Offset (11) [Repeatability]

A1-1.16.1 *Discussion fo TTLX or TTLY*

A1-1.16.1.1 This is the value for determining (with 3σ confidence) whether your probe marks will always fall within your desired spec. They are the hatch-marked lines.

A1-1.17 Step 15 — This normalized die offset includes Die-to-Die, Wafer-to-Wafer, and Setup-to-Setup offsets thus a 3σ variation of this offset will be called Total Prober Variation (TTLX and TTLY).

A1-1.17.1 *Calculate Total Prober Error Range (3σ).*

LOTX + TTLX, LOTX - TTLX = Total Prober X-Error Range (3σ)
LOTY + TTLY, LOTY - TTLY = Total Prober Y-Error Range (3σ)

A1-1.17.2 Suggested Graphs:

X-Offset	Y-Offset
LOTX + TTLX	LOTY + TTLY
LOTX	LOTY
LOTX - TTLX	LOTY - TTLY
Average Die X-Offset (3)	Average Die Y-Offset (3)

A1-1.17.2.1 It is recommended to create one graph illustrating the prober accuracy in X and one graph for Y.

A1-1.18 *Discussion of Graphs (one example for X [Figure X] and one for Y [Figure Y])*

A1-1.18.1 Average Lot X-Offset is the value from Step 10. This number shows where the probe mark distribution is centered (the accuracy of the prober).

A1-1.18.2 Average Lot X-Offset +3σ is the result from step 10 + the result from step 14

A1-1.18.3 Average Lot X-Offset -3σ is the result from step 10 – the result from step 14

A1-1.18.4 These two lines show the ± 3σ range of your distribution. This describes the repeatability of the prober.

NOTE: There will always be explainable and unexplainable accuracy and repeatability errors on a prober. If these two lines fall within your desired specification, you will probably not have any problems. The example graph for X-offset illustrates a well-behaved, or "passing" prober. The example graph for Y-offset, on the other hand, is representative of a prober which failed to meet the desired accuracy specification.

A1-1.18.5 The upper and lower desired specification limits have been added to the graphs.

A1-1.18.6 The final piece of data added to the graph is the Average Die Offset. This, as stated in Step 1, is very good at illustrating any trends throughout the lot.

A1-1.18.7 Tips for graph making:

- Add gridlines across the X-axis to separate wafers.
- Print all graphs (X and Y, different lots, different probers) with the same scale in X and Y.
- Add a legend to your graphs, so that they will be readable by your “audience” as well as yourself.

The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI G79-0200
SPECIFICATION FOR OVERALL DIGITAL TIMING ACCURACY

This specification was technically approved by the Global Automated Test Equipment Committee and is the direct responsibility of the North American Automated Test Equipment Committee. Current edition approved by the North American Regional Standards Committee on September 3, 1999. Initially available at www.semi.org November 1999; to be published February 2000.

1 Purpose

1.1 This standard is intended to provide a minimum common definition of timing accuracy specifications for automatic semiconductor test equipment (ATE).

2 Scope

2.1 The scope of this standard includes all semiconductor ATE capable of digital functional testing. This standard does not include the following:

- test fixturing errors,
- device insertion errors, and
- ATE performance or capability beyond timing accuracy.

2.2 This standard's overall timing accuracy (OTA) definition serves to simplify automatic test equipment comparisons and reduce specification ambiguity.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 Parameters associated with the following items are not covered by the Overall Digital Timing Accuracy Specification:

- minimum driver pulse width,
- comparator bandwidth,
- I/O round trip delay,
- test fixturing errors,
- device insertion errors,
- time measurement unit accuracy, and
- ATE capability or performance beyond timing accuracy.

4 Referenced Standards

None.

5 Terminology

5.1 *Abbreviations and Acronyms*

5.1.1 *ATE* — automatic test equipment

5.1.2 *DUT* — device under test

5.1.3 *NR* — Non-return signal format

5.1.4 *RTx* — return to zero, one or complement signal format.

5.1.5 *SBx* — surround by zero, one or complement signal format.

5.1.6 *Z* — driver off (high impedance)

5.2 *Definitions*

5.2.1 *device insertion errors* — error influenced by device-input capacitance and/or terminations.

5.2.2 *edge* — time delay created by an ATE delay generation resource.

5.2.3 *performance board* — printed circuit board used to interface the tester channels to the device under test.

5.2.4 *pin* — tester channel

5.2.5 *reference load A* — 500 ohms in parallel with 2.5pf (± 0.5pf) to ground

5.2.6 *reference load B* — 50 ohms to ground

5.2.7 *reference load C* —

- 50 ohms to low (for driver z to high and high to z transitions).
- 50 ohms to high (for driver z to low and low to z transitions).

5.2.8 *strobe compare* — monitor DUT output at a single time point.

5.2.9 *test cycle* — inverse of test pattern execution frequency.

5.2.10 *test fixturing errors* — error influenced by mismatched signal path lengths, impedance discontinuities, lumped capacitance/inductance elements, and high frequency loss due to skin effect or interconnects.

5.2.11 *window compare* — monitor DUT continuously during a time interval.

NOTE 1: The term "input" as it appears in this document refers to the device under test.

6 Test Methods

6.1 See Figure 1.

NOTE 2: A verification procedure to complement this Overall Digital Timing Accuracy Specification is currently being developed as a SEMI draft document.

6.2 *Explanation of Figure 1* — This figure is meant to graphically describe Overall Timing Accuracy and its constituent components. Overall Timing Accuracy (OTA) is made up of three components, and by definition is the aggregate timing error comprised of input edge placement accuracy (see Section 7.1.1), output edge placement accuracy (see Section 7.1.2), and input to output timing accuracy (see Section 7.1.3). It's important to note that the OTA specification and associated graphical representation shown in Figure 1 is meant to encompass timing delay errors across multiple machines, as well as multiple calibrations for a single machine over time.

6.2.1 Our experience in dealing with multiple-pin automated test systems reveals that not all input drive circuits can place a drive edge at exactly the same point in time relative to a common reference. The same is true for output compare circuits when placing compare edges. Thus, these edges tend to have an (error) distribution around some average value relative to their intended placement. This is due in part to the inherent anomalies associated with electronic circuits that make-up these edge placement elements. The distribution of edge error is graphically shown for input (see Section 7.1.1) and output edge (see Section 7.1.2) signals in Figure 1.

6.2.2 Drive Input to Compare Output Timing Accuracy (Section 7.1.3) can be described in different ways. It is easy to think of this parameter, per the definition given in this document, Section 7.1.3, as simply the relative time difference (skew) between the drive delay timing error distribution and the compare delay timing error distribution for a particular machine. But this parameter, once established for a machine, is not necessarily constant. For example, this parameter can change from one calibration of a machine at a particular time, to something different, as a result of a subsequent calibration of that same machine. As well, this parameter can also be considered as a machine to machine accuracy parameter, not necessarily having the same value between any two machines of the same kind.

6.2.3 Thus, on each machine and at different points in time for the same machine the Drive Input to Compare Output Timing skew can be uniquely different per machine. That difference being influenced by the various machine anomalies that contribute to machine error including the not so perfect results of a periodic edge calibration.

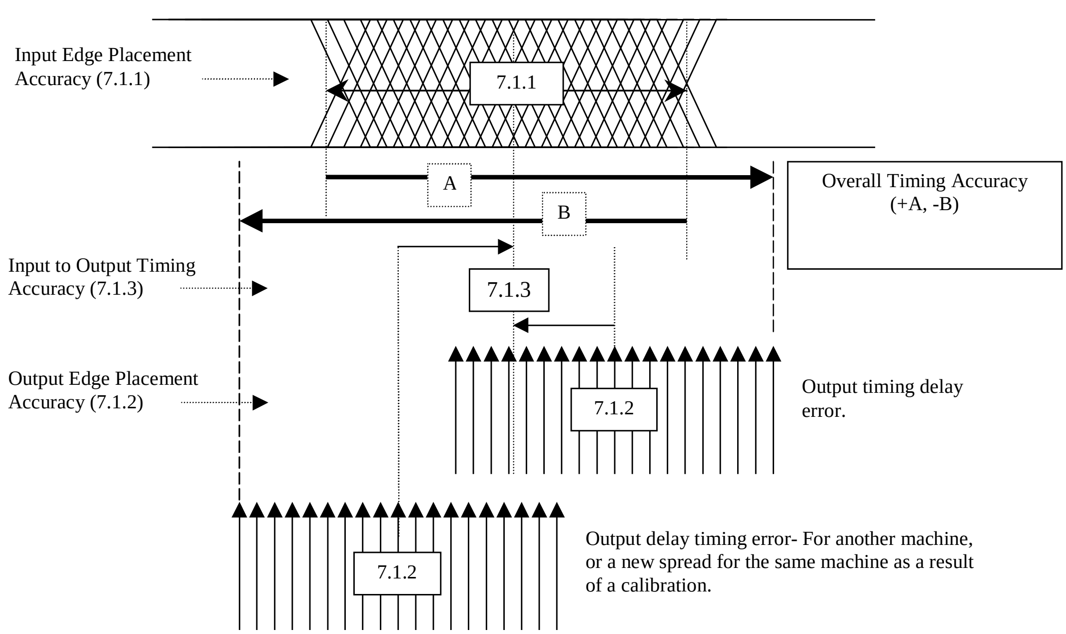

Figure 1
Overall Timing Accuracy

6.2.4 Examination of the OTA definition in the context of Figure 1, that being the general case and not a single point timing evaluation, reveals that the overall timing accuracy time value is the time line indicated by "A" and the time line indicated by "B". In a single point AC timing evaluation, OTA is determined as a distribution of edges associated with time line "A" or time line "B", depending upon the relationship between the drive edge values and compare edge values (see Section 7.1.3) at that point in time.

7 Definitions

7.1 *Overall Timing Accuracy* — aggregate timing error comprised of input edge placement accuracy, output edge placement accuracy and input to output timing accuracy. (See Figure 1.)

7.1.1 *Input Edge Placement Accuracy* — DUT input timing error comprised of input timing delay error, input timing jitter and input transition time variation.

7.1.1.1 *Input Timing Delay Error @ 5V* — time delay error at the midpoint of a 5V transition, with respect to an ideal delay (NIST traceable delay reference), using any pin, any delay value, any input timing edge, any format (NR, Rtx, SBx), positive or negative transition and any test cycle length.

Conditions:

- delays are normalized to pin 1 (first tester pin), rising edge, NR format, @ 0ns;
- errors are normalized to the average of minimum and maximum of the error distribution;[1]
- reference load A; and
- physical reference point is a zero length interconnect on the DUT side of a standard performance board.

7.1.1.2 *Input Timing Delay Error @ 3V* — (same as Section 7.1.1.1 @ 3V)

7.1.1.3 *Input Timing Delay Error @ 1V* — (same as Section 7.1.1.1 @ 1V)

7.1.1.4 *Input Timing Jitter* — short term (cycle to cycle) instability using any pin, any input timing edge, any format (NR, RTx, SBx).

Conditions:

- error expressed as RMS value;
- reference load B;
- physical reference point is a zero length interconnect on the DUT side of a standard performance board; and
- error referenced to corresponding transition of prior cycle.

7.1.1.5 *Input Transition Time Variation @ 5V* — minimum and maximum rise and fall times of a 5V input signal transition using any pin.

Conditions:

- referenced to the time variation between the 20% and 80% points of both positive and negative signal transitions;
- reference load A; and
- physical reference point is a zero length interconnect on the DUT side of a standard performance board.

7.1.1.6 *Input Transition Time Variation @ 3V* — (same as Section 7.1.1.5 @ 3V)

7.1.1.7 *Input Transition Time Variation @ 1V* — (same as Section 7.1.1.5 @ 1V)

7.1.2 *Output Edge Placement Accuracy* — DUT output compare timing error comprised of output timing delay error and output compare timing jitter.

7.1.2.1 *Output Timing Delay Error @ 5V* — time delay error at the detected midpoint of a 5V transition, with respect to an ideal delay (NIST traceable reference), using any pin, any delay value, any compare timing edge, window or strobe compare mode, expect H or L, positive or negative transition and any test cycle length.

Conditions:

- measured with load circuit "off" or high impedance;
- delays normalized to rising edge detected by pin 1 (first tester pin), using strobe compare format, expect H @ 0ns;
- error normalized to the average of minimum and maximum of the error distribution; and
- input signal: 50-ohm source, 0–5V step, > 1V/ns, inserted at a zero length interconnect on the DUT side of a standard performance board.

7.1.2.2 *Output Timing Delay Error @ 3V*— (same as Section 7.1.2.1 using 3V input signal)

7.1.2.3 *Output Timing Delay Error @ 1V* — (same as Section 7.1.2.1 using 1V input signal)

1 "Average of min and max of the error distribution" is defined as: (min error + max error)/2. This can also be referred to as "center of spread".

7.1.2.4 *Output Timing Jitter*— short term (cycle to cycle) instability using any pin, any compare timing edge, window or strobe compare mode, expect H or L.

Conditions:

- error expressed as RMS value;
- physical reference point is a zero length interconnect on the DUT side of a standard performance board; and
- jitter referenced to an independent synchronous trigger.

7.1.3 *Input to Output Timing Accuracy* — relative time difference between the average of minimum and maximum drive input delay timing and the average of minimum and maximum compare output delay timing.

7.1.3.1 *Input to Output Timing Error @ 5V* — relative time difference between the average of minimum and maximum input delay timing error @ 5V (Section 7.1.1.1) and the average of minimum and maximum output timing delay error @ 5V (Section 7.1.2.1).

Conditions:

- (same as Sections 7.1.1.1 and 7.1.2.1).

7.1.3.2 *Input to Output Timing Error @ 3V* — same as Section 7.1.3.1 using 3V input signal and definitions/ conditions specified in Sections 7.1.1.2 and 7.1.2.2.

7.1.3.3 *Input to Output Timing Error @ 1V* — same as Section 7.1.3.1 using 1V input signal and definitions/ conditions specified in Sections 7.1.1.3 and 7.1.2.3.

7.1.4 *High Speed Clock Accuracy* — DUT high speed clock input timing error (if different than normal tester input channels) comprised of high speed clock delay error, high speed clock self-trigger cycle jitter, high speed clock self-trigger phase jitter and high speed clock transition time variation.

7.1.4.1 *High Speed Clock Delay Error @ 5V* — time delay at the midpoint of a 5V transition, with respect to an ideal delay (NIST traceable delay reference), using any pin, any delay value, any input timing edge, RTZ format, and any test cycle length.

Conditions:

- delays are normalized to pin 1 (first tester pin), rising edge, NR format, @ 0ns;
- errors are normalized to the average of minimum and maximum of the error distribution;
- reference load A; and
- physical reference point is a zero length interconnect on the DUT side of a standard performance board.

7.1.4.2 *High Speed Clock Delay Error @ 3V* — (same as Section 7.1.4.1 @ 3V)

7.1.4.3 *High Speed Clock Delay Error @ 1V* — (same as 7.1.4.1 @ 1V)

7.1.4.4 *High Speed Clock Self-trigger Cycle Jitter* — short term instability using any high speed clock pin, from a rising clock edge to the next rising clock edge, or falling clock edge to the next falling clock edge.

Conditions:

- error expressed as RMS value;
- reference load B; and
- physical reference point is a zero length interconnect on the DUT side of a standard performance board.

7.1.4.5 *High Speed Clock Self-trigger Phase Jitter* — short term instability using any high speed clock pin, from a rising clock edge to the next falling clock edge, or falling clock edge to the next rising clock edge.

Conditions:

- error expressed as RMS value;
- reference load B; and
- physical reference point is a zero length interconnect on the DUT side of a standard performance board.

7.1.4.6 *High Speed Clock Transition Time Variation @ 5V* — minimum and maximum rise and fall times of a 5V input signal transition using any high speed clock pin.

Conditions:

- referenced to the 20% and 80% points of a positive and negative signal transition;
- reference load A; and
- physical reference point is a zero length interconnect on the DUT side of a standard.

7.1.4.7 *High Speed Clock Transition Time Variation @ 3V* — (same as Section 7.1.4.6 @ 3V)

7.1.4.8 *High Speed Clock Transition Time Variation @ 1V* — (same as Section 7.1.4.6 @ 1V)

7.1.5 *Input Timing Delay Error for Z to Drive High/Low* — Time delay error at the midpoint of a driver transition from Z to high/low, with respect to an ideal delay, using any pin, any delay value, any Z control timing edge, any Z transition format, and any test cycle length.

NOTE 3: This definition does not include I/O timing restrictions imposed by the round trip delay between the tester electronics and the DUT.

Conditions:

- delays are normalized to pin1 (first tester pin), rising edge, NR format, 5V, @ 0ns;
- errors are normalized to the average of minimum and maximum of the error distribution;
- reference load C; and
- physical reference point is a zero length interconnect on the DUT side of a standard performance board.

7.1.6 *Input Timing Delay Error for Drive High/Low to Z* — Time delay error at the midpoint of a driver transition from high/low to Z, with respect to an ideal delay, using any pin, any delay value, any Z control timing edge, any Z transition format, and any test cycle length.

NOTE 4: This definition does not include I/O timing restrictions imposed by the round trip delay between the tester electronics and the DUT.

Conditions:

- delays are normalized to pin1 (first tester pin), rising edge, NR format, 5V, @ 0ns;
- errors are normalized to the average of minimum and maximum of the error distribution;
- reference load C; and
- physical reference point is a zero length interconnect on the DUT side of a standard performance board.

SEMI G80-0200
TEST METHOD FOR THE ANALYSIS OF OVERALL DIGITAL TIMING ACCURACY FOR AUTOMATED TEST EQUIPMENT

This test method was technically approved by the Global Automated Test Equipment Committee and is the direct responsibility of the North American Automated Test Equipment Committee. Current edition approved by the North American Regional Standards Committee on September 3, 1999. Initially available at www.semi.org December 1999; to be published February 2000.

1 Purpose

1.1 This procedure will define a standard process whereby any logic integrated circuit (IC) ATE system can be evaluated for parameters that makeup an AC timing accuracy specification.

1.2 Application of this procedure will simplify ATE comparisons, reduce specification ambiguity, simplify user acceptance procedures, simplify ATE performance monitoring, and provide a common validation criteria for ATE suppliers.

2 Scope

2.1 This procedure is intended for analysis of timing accuracy specifications for all semiconductor automatic test equipment (ATE) capable of digital functional testing. The extent of the analysis includes overall timing accuracy and the primary components of overall timing accuracy as defined in the definition section of this document.

2.2 This procedure does not include analysis of the following parameters associated with ATE timing accuracy:

- minimum driver pulse width,
- comparator bandwidth,
- I/O round trip delay,
- test fixturing errors,
- device insertion errors,
- time measurement unit (TMU) accuracy, and
- ATE capability or performance beyond AC timing accuracy.

2.3 Application of this procedure can reduce equipment acceptance time resulting in savings for both the end-users and ATE suppliers.

2.4 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 The following limitations are inherent to this procedure:

3.1.1 The tolerances of each measurement used in the procedure are listed in each test, where appropriate.

3.1.2 The verification methods do not include varying environmental conditions, so results may not reflect performance at environmental limits.

3.1.2.1 Due to execution time limits, the verification procedure does not represent an exhaustive analysis. The number of data points analyzed is intended to provide a minimum representative assessment of AC timing accuracy parameters in a practical amount of time.

3.1.3 This method uses only edge compare mode and non-multiplexed operation in providing a minimum representative assessment of AC timing accuracy.

3.1.4 This method does not determine the effects that duty cycle variations have on AC timing accuracy.

3.1.5 Not being an exhaustive analysis this method avoids comprehensive testing as might be expected for complex AC timing functions such as on-the-fly (OTF) timing. This method was defined with the intention of keeping the data gathering practical such that meaningful results are obtained in a reasonable amount of time. In the case of timing-on-the fly a routine is contained in this method and can be used as a reference parameter for comparative purposes when systems with on-the-fly timing are analyzed. Thus only the most fundamental AC timing results are produced and OTF timing is not included as part of the overall timing accuracy (OTA) results.

3.1.6 Discretion is advised when interpreting OTA results obtained from this method. Self-analysis cannot allow for all error components to be isolated. Thus good (compliant) method results should be viewed with caution as potentially compliant. On the other hand, poor (non-compliant) method results are a strong indication that the system under evaluation is questionable regarding its accuracy and most likely non-compliant.

4 Referenced Standards

4.1 *SEMI Standard*

SEMI G79 — Specification for Overall Digital Timing Accuracy

5 Terminology

5.1 *Abbreviations and Acronyms*

5.1.1 *1*[1] — tester output driver high level

5.1.2 *0*[2] — tester output driver low level

5.1.3 *ATE* — automated test equipment

5.1.4 *DUT* — device under test

5.1.5 *H*[3] — tester input comparator expect high level.

5.1.6 *L*[4] — tester input comparator expect low level.

5.1.7 *n* — highest pin/channel number, and Pin 1 — refers to the lowest pin/channel number.

5.1.8 *NR* — non-return signal format

5.1.9 *RTO* — return to one signal format.

5.1.10 *RTZ* — return to zero signal format.

5.1.11 *SBC* — surround by complement signal format.

5.1.12 *Z* — tester output driver high impedance ("off") state.

5.2 *Definitions*

5.2.1 *device insertion errors* — error influenced by device-input capacitance and/or terminations.

5.2.2 *edge* — time delay created by an ATE delay generation resource.

5.2.3 *high bandwidth oscilloscope* — digital sampling oscilloscope with > 10 GHz bandwidth, using probes with > 1 GHz bandwidth, 500 ohm input impedance, 2.5pF ± 0.5pF input capacitance and < 0.125" ground lead.

5.2.4 *pin* — tester channel

5.2.5 *performance board* — printed circuit board used to interface the tester channels to the device under test.

5.2.6 *test fixturing errors* — error influenced by mismatched signal path lengths, impedance discontinuities, lumped capacitance/inductance elements, and high frequency loss due to skin effect or interconnects.

1 This convention is not universal. Sometimes a "H" is used.

2 This convention is not universal. Sometimes a "L" is used

3 This convention is not universal. Sometimes a "1" is used.

4 This convention is not universal. Sometimes a "0" is used.

5.2.7 *window compare* — monitor device continuously during a time interval.

5.2.8 *zero_reference_measurement* — oscilloscope measurement of the midpoint of a 0–3v NR signal rising edge with delay = 0s. This is an arbitrary reference signal selected by the user of this method. The method user is free to choose a convenient reference signal that will allow consistent use of that signal for making edge placement timing measurements during tests described in level 2 of this procedure.

6 Summary of Method

6.1 This procedure provides a hierarchical, generic method of analyzing ATE timing accuracy. The hierarchy supports two levels of specification analysis. Broad, composite net results are available by using the ATE for self-analysis in Level 1.

6.2 At this level, a large amount of data can be efficiently collected, representing the net conformance to overall timing accuracy specifications. This technique, however, precludes isolation and detailed analysis of specific accuracy components. Therefore, a second level of analysis, incorporating external instruments is included. While the first level provides efficient, broad analysis, the second level provides less efficient, detailed analysis.

6.3 Results from the analyses are saved in a standard format to facilitate further use for application specific data reduction. The minimum format is:

test #, channel #, min value, max value

6.3.1 *Verification Procedure Summary*

6.3.1.1 *Level 1 ATE Self-Analysis*

- Highly Efficient
- Broad Scope
- Moderate Error Observability
- Drive Input to Compare Output Tests
    - 3 Voltages
    - 2 Pin Directions
    - 503 Test Cycles[5]
    - 503 Pulse Widths
    - 12 Transitions[6]
    - 4 Formats
- Extended Delay Tests

5 Reference Figure 3.

6 Reference Figure 2.

- Drive Z-State Tests
- Multiple Period Tests

6.3.1.2 *Level 2 External Measurements*

- Inefficient w/o Automation
- Focused Scope
- Good Error Observability
  - Drive (input) Timing Test
  - Compare (output) Timing Test
  - Driver Rise Time Test
  - Drive (input) Timing Cycle Jitter Test
  - High Speed Clock Test

7 Requirements

7.1 *Acceptance Tests* — Before initiating the test process, the ATE under evaluation is to be certified by a representative of the manufacturer or end-user to be fully operational.

7.2 *Personnel Qualification* — The individual(s) operating the ATE under evaluation must be certified or otherwise qualified to operate this equipment, and be familiar with the procedures for performing the analysis called-out in this document.

7.3 *Supplemental Equipment* — The following equipment is required: A digital sampling oscilloscope with > 10 GHz bandwidth, probes with > 1 GHz bandwidth, 500 ohm input impedance, 2.5 pF ± 0.5pF input capacitance, and < 0.125" ground lead. It is important that this equipment requirement step be met. Tolerances called-out in various steps of this procedure were chosen to be consistent with the general equipment specified in this equipment specification requirement.

7.4 *This Procedure* — It is highly recommended that the user of this method read this document (SEMI G80) in its entirety.

7.5 *System* — Test system usage will be available on a continuous basis and uninterrupted during the allotted time needed to perform this timing analysis procedure.

7.6 *Application Program* — It is required that an application program be written to perform the steps called-out in this procedure. That program will act as a means of reliable and consistent interaction between the tester and supplemental equipment. In so executing, that program will also facilitate the data collection process that will ultimately lead to the timing analysis conclusions this procedure produces.

7.7 *The Method* — The recommended procedure, contained primarily in Section 10 of this document, is generically written and will serve as a guide in producing the required program, written in the test application software language of the system under evaluation.

7.8 *ATE System Performance (Load) Boards* — To collect data two performance/load boards will be required. For one of these performance boards it is recommended that adjacent tester channels be shorted together with minimum and equal length interconnections. This board will facilitate the data collection process for Level 1 and in part for Level 2. The second board is to have an open driver to comparator connection and will be used for Level 2 drive input timing tests. Reference Figures 1 and 4.

7.9 *Exceptions* — It is expected that the user of this method execute the procedures as described in this document. If the method user should choose to deviate from the procedures recommended in this document it is expected that an appropriate description of that deviation be entered in the EXCEPTIONS PAGE provided in Appendix 3.

8 Test Conditions

8.1 *Environmental* — It is a requirement that the procedure called-out in this document be executed within the intended environmental operating conditions specified by the equipment supplier. Operating temperature requirements specified by the equipment supplier must be maintained.

8.2 *Optional Execution* — The user of this procedure may consider rerunning this procedure at environmental (temperature) extremes other than nominal.

8.3 *Warm-up Period* — It is essential that all equipment used or under evaluation be allowed to warm-up in accordance with the manufacturer's specified requirements for equipment stabilization.

8.4 *Optional Data Collection* — Data may be taken immediately after equipment calibration. However, the user of this procedure may wish to take additional data at subsequent time intervals, but within the known good calibration window for the system under evaluation.

9 Preparation of Apparatus

9.1 *Equipment Configuration* — The equipment under evaluation must be configured for its normal and intended operation. No special considerations such as additional cooling or removal of equipment skins are to be undertaken.

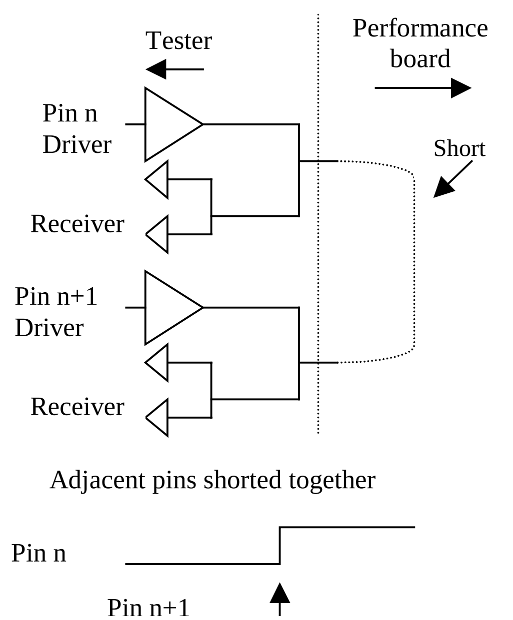
9.2 *Equipment Calibration* — The equipment under evaluation must be fully calibrated before this procedure is executed. No special calibration is to be performed and the equipment is to be configured for normal and intended operation.

9.3 *Supplemental Equipment Calibration* — External equipment used for level 2 data collection in this procedure must be verified for proper calibration.

10 Test Method Procedure

10.1 The procedure is comprised of Level 1 tests and Level 2 tests. Any ATE capability described in the following tests that is not available on the ATE under analysis is not required for compliance to the procedure, but should be noted in the verification results Table 1 and Table 2.

10.2 Each test system is different; thus this procedure is generic. Regardless, it will provide comprehensive results when the specific application is created using this procedure as a guide. Per the requirements, a load board and application program written to accommodate the procedure should be in place when the procedure is executed. This procedure is to be executed per the requirements outlined in Section 7 of this document. When these requirements are met, the following steps will comprise the step by step process for execution of this Test Method:



Pairs of adjacent tester pins are shorted together with a minimum length interconnect on the performance board.

Figure 1
Level 1 Verification

1. Install the performance board.

2. Power up the system and supplemental equipment, allow adequate time for stabilization.

3. Load the appropriate application program that represents the embodiment of the procedure called out in Sections 10.3.1, 10.3.4, 10.3.5, and 10.3.6 for Level 1 as well as Sections 10.4.1, 10.4.2, 10.4.3, 10.4.4, 10.4.5, and 10.4.6 for Level 2.

4. Execute the method to completion. The application program can capture the data for Level 1 and Level 2 and store that for later analysis.

5. This procedure calls for various time measurements to be made at specified voltage points or signal levels. The user is encouraged to maintain these values to keep the method results constants when system to system comparisons are being made. Regardless, he is free to adjust these measurement points or levels to accommodate specific integrated circuit technology requirements important to that product and the system being analyzed. When that occurs documentation of those procedure variations must be entered in Appendix 3 (Exceptions Page).

6. Best results from this procedure are achieved if a consistent measurement methodology is maintained. This is important when making time measurements relative to a particular transition point on a signal edge. This method recommends that when signal measurements are specified at a particular transition point, i.e., 50%, that this point on the edge be determined relative to the 0% or 100% steady state levels displayed on the oscilloscope, after any aberrations due to the transition have expired. A tester reference channel, the lowest channel, should be used to set the measurement point(s) and then consistently used as the basis for subsequent measurements for the remaining tester channels.

7. *Data Analysis* — Analyze the captured data and make the appropriate data entries to Table 1, provided in this method document.

8. When this method execution is complete, document all method exceptions in the EXCEPTIONS section of this document (Appendix 3).

9. *Results* — Data entry to Table 2. Make the appropriate data entries to Table 2, provided in this method document and supplemented with examples contained in Appendix 2.

10.2.1 Level 1 requires no external equipment for completion, whereas Level 2 does require use of external equipment. The user is free to implement this procedure through total manual intervention. On the other hand, the user may choose to apply an automated or robotic approach to data collection for Level 2. Regardless, the user is advised that tester and external equipment interaction accommodated by the application program is necessary for data collection at Level 2.

10.3 *Level 1 Tests* — Level 1 tests are intended to efficiently gather a large amount of data by taking advantage of the self-analysis ability of the ATE. This is accomplished by shorting adjacent tester channels together on a performance board with minimum, equal length interconnections, and using one channel to test the other. Reference Figure 1. Execution speed and system resource coverage are of primary importance for Level 1. Level 1 is intended to analyze specification conformance as opposed to diagnose system failures. All measurements are normalized to "zero" in order to facilitate subsequent data reduction/analysis. Level 1 is intended to collect data only. Data reduction and processing are to be done off-line in order to maximize data collection efficiency.

10.3.1 *Timing Linearity Test* — This test is used to establish drive input to compare output timing accuracy by "stretching" the test cycle in minimum cycle programming increments while using fixed percentage delays and pulse widths as the method sweeps through various timing conditions. The test pattern should be written to switch all even or odd pins simultaneously, and for all transitions and associated strobes to occur at least 100 times for each data point.

10.3.2 For clarification all drive edges are detected in parallel in pairs. The intention is to sweep the compare edge and detect the earliest occurrence of a drive edge with the latest compare edge, as well as detect the latest occurrence of a drive edge with the earliest compare edge.

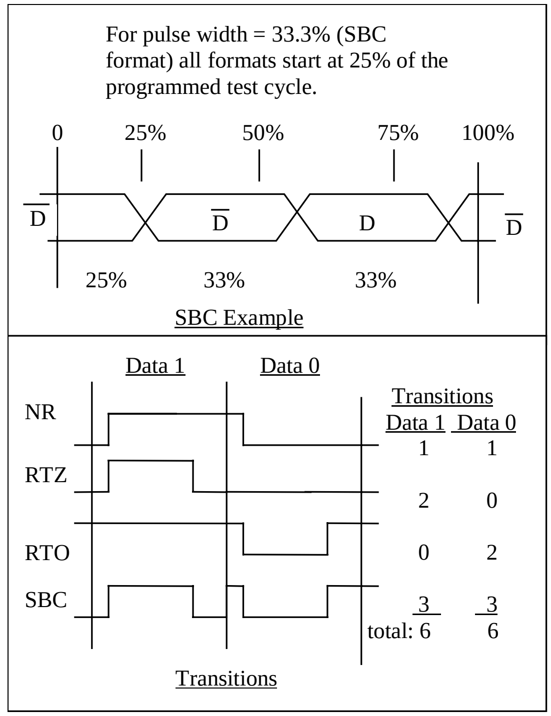


Figure 2
SBC Example and Transitions

10.3.3 The following Test Cycle Example and nested loop outline describes the test flow:

for amplitude = 1V, 3V, 5V
  for direction =
    odd_pins_drive_&_even_pins_compare to
    even_pins_drive_&_odd_pins_compare
   for test_cycle = min_cycle to [min_cycle +
    500*cycle_resolution] by
    cycle_resolution, 3x min_cycle, 10x min cycle

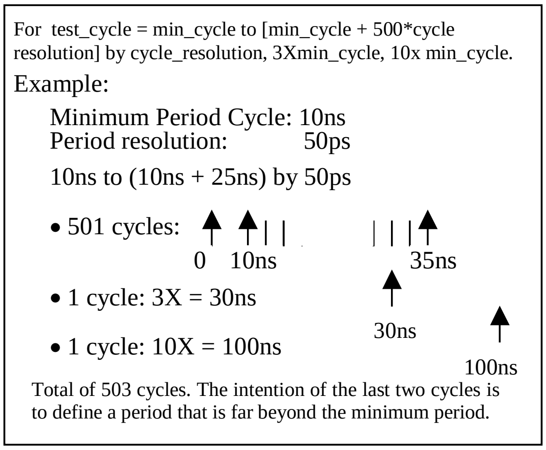

Figure 3
Test Cycle Example

10.3.4 *Extended Delay Test* — This test is used to establish drive input to compare output timing accuracy when timing generator delay values are programmed beyond the length of the test cycle. Driver input delays are programmed to occur in subsequent test cycles and detected with compare delays originating in the corresponding subsequent test cycle. The intention is the same as Section 10.3.1 with the exception that edges are programmed into a subsequent cycle. Conditions such as formats and voltages have been reduced to keep the amount of data collected down to a reasonable level.

10.3.4.1 The following nested loop outline describes the test flow:

```
for amplitude = 3V
  for direction =
        odd_pins_drive_&_even_pins_compare to
        even_pins_drive_&_odd_pins_compare
    for test_cycle = min to 10*min by 0.1*min
      for format = NR
        for format_delay = test_cycle to max_delay by
          0.25*test_cycle (max delay is beyond the cycle
                                boundary)
              detect earliest occurrence of format
                    transition midpoint with the latest
                    compare pin using pattern expect
                    data shifted into the appropriate cycle
              detect latest occurrence of format transition
                    midpoint with the earliest compare pin
                    using pattern expect data shifted into
                    the appropriate cycle
              error = (latest occurrence - earliest
                          occurrence)
            end delays
          end format
        end test cycles
      end directions
    end amplitude
```

10.3.5 *Driver Z State Test* — This test verifies the timing accuracy of tester driver transitions from Z to 1/0 and from 1/0 to Z. Driver inputs are programmed to transition to and from Z and 1/0 while being loaded with 50 ohms terminated to drive 1 for Z to 0 and 0 to Z, and 50 ohms terminated to drive 0 for Z to 1 and 1 to Z[7] (reference load C). The following nested loop outline describes the test flow:

```
for amplitude = 3V
  for direction =
     odd_pins_drive_&_even_pins_compare to
     even_pins_drive_&_odd_pins_compare
     for test_cycle = 5*min_cycle
       for format_delay = 50%
         for format = NR
           detect earliest occurrence of Z to low tran-
              sition at scaled midpoint with compare pins
           detect latest occurrence of Z to low tran-
              sition at scaled midpoint with compare pins
           error=(latest occurrence - earliest occurrence)
           detect earliest occurrence of Z to 1 tran-
              sition at scaled midpoint with compare pins
           detect latest occurrence of Z to 1 transition
              at scaled midpoint with compare pins
           error = (latest occurrence - earliest occur-
                      rence)
           detect earliest occurrence of 0 to Z transition
              at scaled midpoint with compare pins
           detect latest occurrence of 0 to Z transition at
              scaled midpoint with compare pins
            error = (latest occurrence - earliest occur-
                       rence)
            detect earliest occurrence of 1 to Z tran-
              sition at scaled midpoint with compare pins
            detect latest occurrence of 1 to Z transition
              at scaled midpoint with compare pins
            error = (latest occurrence - earliest occur-
                       rence)
         end format
       end format_delay
     end test_cycle
    end direction
end amplitude
```

10.3.6 *Multiple Period Test*[8] — This is an optional test to be run only if the ATE supports dynamic (or "on-the-fly") time set switching. This test intention is similar to Section 10.3.1 and 10.3.4 (timing linearity and extended delay tests) except that the test period and delay changes are generated dynamically within a

7 Tying two drivers together or connecting a resistor to a logic point is acceptable. Note: Load "C": 50 ohms to low for driver z to high and high to z transitions. And 50 ohms to high for driver z to low and low to z transitions.

8 This algorithm requires 64 time sets. If the equipment does not have 64 time sets, adjust the algorithm to accommodate the amount available and note the differences on the exception page, Appendix 3.

single test pattern burst. The following nested loop outline describes the test flow:

for amplitude = 1V, 3V, 5V
  for direction =
      odd_pins_drive_&_even_pins_compare to
      even_pins_drive_&_odd_pins_compare
    execute single pattern with the following
    dynamic changes:

Test Cycle	*Drive Format*	*Format Offset*	*Pulse Width*	*Drive Data*	*Compare Offset*	*Expect Data*

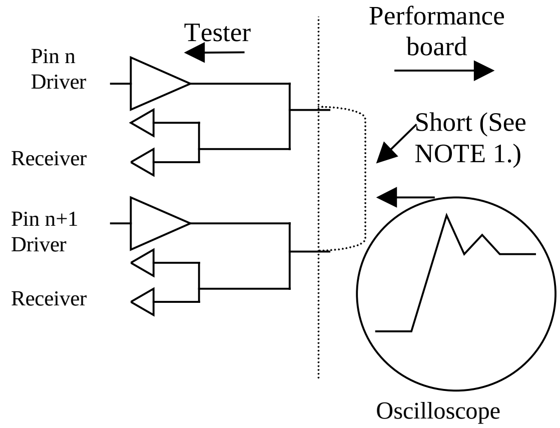
      detect earliest occurrence of format
          transition midpoint with the latest
          compare pin
      detect latest occurrence of format transition
          midpoint with the earliest compare pin
      error = (latest occurrence - earliest occurrence)
  end direction
end amplitude



Pairs of adjacent tester pins can be shorted together with a minimum length interconnect on the performance board.

A reference for the oscilloscope measurement is required. That reference can be any signal synchronized to the test system's timing. The reference signal chosen should be consistent and stable. Examples of this may be another tester pin or master oscillator reference signal.

NOTE 1: The user of this method may find improved driver signal attributes using an open circuit performance board, versus the shorted board indicated here for Level 2 Drive Input Timing Error data collection. On the other hand the shorted performance board, using the driver as the signal source, is a viable approach for the Compare Output Timing Error Test. Regardless, the user may optionally choose to use a pulse generator as the signal source for the Compare Output Timing Error test. The 50-ohm pulse generator must have edge speeds that are comparable to the driver it is replacing. Test setup conditions and the pulse generator rise time employed must be documented on the exception page (Appendix 3).

Figure 4
Level 2 Verification

10.4 *Level 2 Tests* — The efficiency of data collection with Level 1 tests may preclude isolation of certain specification components. The self-analysis procedures may also mask some error terms that contribute to other specification components. Therefore, Level 2 modules are intended to supplement Level 1 results by using external instruments to distinguish individual specification components and provide detailed analysis of potentially masked results. The use of external instruments facilitates independent observation of individual parameters, but requires physical movement of a probe (unless automated with robotics), which results in less efficient data collection. Reference Figure 4.

10.4.1 *Drive Input Timing Error Test* — Since the driver input timing error cannot be distinguished from compare output timing error with Level 1 tests[9] an external instrument must be used to isolate the driver input timing error from compare output timing error. An external instrument is also required to identify pin to pin "skew" beyond adjacent pins, since Level 1 only uses adjacent pin pairs for analysis. This requires independent measurements of representative driver input timing conditions. The reference for measurement of driver input timing error is a high bandwidth-digital sampling oscilloscope. Exhaustive testing of all pins is impractical, so a reduced set of representative conditions is used. A non-binary pin sampling increment is used to ensure that traditional binary architectural boundaries are crossed. The tolerance for the driver input timing error test is ± 20ps[10] due to the tester/instrument interaction using a generic measurement method. The following nested loop outline describes the test flow:

```
for amplitude = 3V
  for pin = 1 to n by 3
    for test_cycle = min, 2*min, 3*min, 10*min
      for format_delay = 50% of test cycle
          for format = NR, RTZ, RTO, SBC
            for all format transitions
              detect midpoint of drive transition with
                 oscilloscope  (averaging = 8)
              error = (measured_delay - pro-
                     grammed_format_edge_time -
                     zero_reference_measurement)
            end transitions
         end format
      end format_delay
    end test_cycle
  end pin
end amplitude
```

10.4.2 *Compare Output Timing Error Test* — Since the compare output timing error cannot be distinguished from driver input timing error with Level 1 tests, an external reference must be used to isolate compare output timing error from driver input timing error. This requires independent measurement of representative compare timing conditions. Each tester driver is used to provide a synchronous reference signal by shorting adjacent tester channels together on a performance board with minimum, equal length interconnections. The actual delay of the driver signal is verified with a high bandwidth-digital sampling oscilloscope. (See Figure 4.)

NOTE 2: If a signal reflection is present at the midpoint of the observed signal (due to a long distance from the performance board to the tester receiver), then the 25% point of the reference driver waveform should be used, instead of the midpoint - as specified below.

10.4.2.1 Exhaustive testing of all pins is impractical, so a reduced set of representative conditions are used. A non-binary pin sampling increment is used to ensure that traditional binary architectural boundaries are crossed.

10.4.2.2 The following nested loop outline describes the test flow:

```
for amplitude = 3V
  for pin = 1 to n by 3
    for test_cycle = min, 2*min, 3*min, 10*min
      for format_delay = 50% of test_cycle
         for format = NR
            for edge = rising, falling
              detect midpoint of NR drive signal with
                 oscilloscope  (averaging = 8)
              detect midpoint of drive transition with
                 comparator (strobe compare mode)
              error = (measured_delay - pro-
                     grammed_compare_delay -
                     zero_reference_measurement)
         end edge
       end format
      end format_delay
    end test_cycle
  end pin
end amplitude
```

NOTE 3: Midpoint detection of the NR drive signal should be done via a compare edge sweep technique.

10.4.3 *Driver Transition Time Test* — Since driver transition time errors can be masked by compare timing errors and comparator bandwidth limitations, an external instrument is required to measure driver transition time errors. The reference used for driver transition time measurements is a high bandwidth-digital sampling oscilloscope.

10.4.3.1 The tolerance for driver transition time measurements is ± 150ps[11] due to the tester/instrument

9 See APPENDIX 2, Section A2-1.3 and Appendix 2, Examples for an explanation.

10 When recording measurements, data log all measurements as they are taken from the measurement equipment and show the associated equipment tolerance as a separate entity.

11 This 150ps tolerance has been extended beyond 20ps due to level sensitivities associated with oscilloscopes and typical bandwidth variations in oscilloscope probes rendering transition time measurements less accurate.

interaction using a generic measurement method. The signal measurement should be made with the driver loaded with reference load A (500 ohms in parallel with 2.5pF ± 0.5pF of capacitance). The following nested loop outline describes the test flow:

```
for amplitude = 1V, 3V, 5V (optional)
  for pin = 1 to n
    for edge = rising to falling
         measure the 20% to 80% transition time of a
         NR driver signal with test cycle = 10*min,
         delay = 0s  using oscilloscope (averaging = 8)
         error = maximum transition time - minimum
                transition time
    end edge
  end pin
end amplitude
```

10.4.3.2 The transition time measurements are to be made between the measured 20% and 80% points of both positive and negative signal edges, i.e., the 20% and 80% points on the signal transition edge relative to a 0% or 100% steady state level displayed on the oscilloscope. Ideally, measurement points chosen should be referenced to a steady state level that results after all aberrations in the transition have expired. Use the lowest tester pin as a reference channel when setting the measurement points for these measurements.

10.4.3.3 ATE systems may use a focused calibration routine for driver pins. That routine is intended to correct edge error due to transition time variations. In the context of executing this method for a machine that has this capability, the user of this method is advised to: 1) Execute the Drive Input Transition Time Variation test regardless, and 2) Enter the test results to the method data summary, Table 2. The entry in Table 2 for transition variation will be a reference parameter. This method as defined is incapable of making drive edge error measurements that exclude transition variation and jitter.

10.4.4 *Driver Input Timing Cycle Jitter Test*[12] — Since driver input timing jitter cannot be determined from Level 1 tests, an external instrument must be used to measure short term, cycle to cycle (or period) instability. This can be done by making period measurements of the driver-input channel under test, with a high bandwidth, digital sampling oscilloscope. A 50-ohm probe should be used to minimize measurement jitter. The tolerance for this test is ± 20ps[13] (min-max) due to the tester/instrument interaction using a generic measurement method. The measurement results are expressed as RMS. This measurement depends on the jitter distribution being Gaussian. Reference Appendix 4 for additional detail regarding this measurement. If in the application of this method it is determined that the jitter is non-Gaussian, skip this test and make the appropriate notation on the exceptions page (Appendix 3).

10.4.4.1 The following nested loop outline describes the test flow:

```
for pin = 1 to n
  for amplitude = 3V
    for test_cycle =  2*min
      for format = RTZ
           for format_delay = 50%
             for pulse_width = 50%
               for i = 1 to 1000
   meas(i) = measure the period of the pin under test
                end i
   measured signal  jitter = RMS spread of meas(1)
                through meas(1000)
              end pulse_width
            end format_delay
      end format
    end test_cycle
  end amplitude
end pin
measured instrumentation jitter = RMS spread of
        oscilloscope trigger
       (method described further in  Appendix 4)
actual RMS signal jitter = measured signal jitter -
        measured instrumentation jitter
(via sum of squares - reference Appendix 4)
```

Reference load B (50 ohms to ground) should be used for this measurement.

10.4.5 *High Speed Clock Self-trigger Cycle Jitter Test* — If the ATE is configured with dedicated high speed clock pins, an external instrument must be used to measure short term, cycle to cycle (or period) instability.

12 Trigger off the scope probe for this and the subsequent jitter test. Use a high persistence display to show signal jitter. Use of a high bandwidth-sampling oscilloscope with statistical capability is recommended. Instrumentation jitter should be extracted from the measured signal jitter, as explained in Appendix 4.

13 When recording measurement data, log all measurements as they are taken from the measurement equipment and show the associated equipment tolerances as a separate entity.

10.4.5.1 This can be done by making period measurements of the high speed clock channel under test, with a high bandwidth, digital sampling oscilloscope. A 50-ohm probe should be used to minimize measurement jitter. The tolerance for this test is ± 20ps (min-max) due to the tester/instrument interaction using a generic measurement method. The measurement results are expressed as RMS. This measurement depends on the jitter distribution being Gaussian. Reference Appendix 4 for additional detail regarding this measurement. If in the application of this method it is determined that the jitter is non-Gaussian, skip this test and make the appropriate notation on the exceptions page (Appendix 3). The following nested loop outline describes the test flow:

```
for pin = (all high speed clock pins)
 for amplitude = 3V
 for test_cycle = 10*min to min by min
      for clock_delay = 50%
        for i = 1 to 1000
meas(i) = measure the period of the clock pin under
test
        end i
measured signal jitter = RMS spread of meas(1)
       through meas(1000)
      end format_delay
    end test_cycle
  end amplitude
end pin
measured instrumentation jitter = RMS spread of
        oscilloscope trigger
       (method described further in  Appendix 4)
actual RMS signal jitter = measured signal jitter -
        measured instrumentation jitter
(via sum of squares - reference Appendix 4)
```

Reference load B (50 ohms to ground) should be used for this measurement.

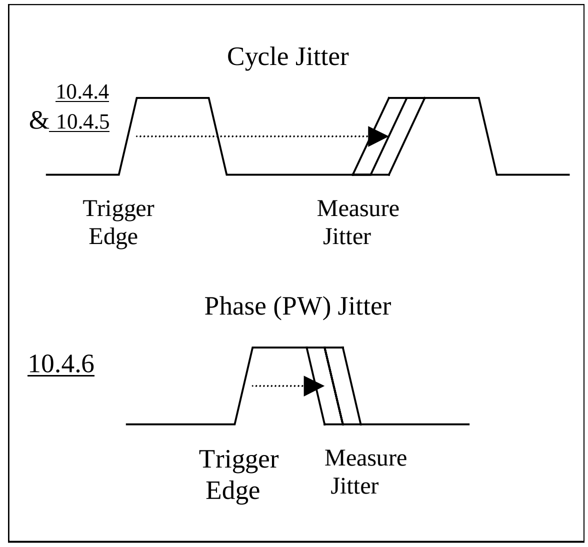


Figure 5
Jitter Tests – Sections 10.4.4, 10.4.5 and 10.4.6

10.4.6 *High Speed Clock Self-trigger Phase Jitter Test* — If the ATE is configured with dedicated high speed clock pins, an external instrument must be used to measure short term, phase (or duty cycle) instability. This can be done by making pulse width measurements of the high speed clock channel under test, using a high bandwidth, digital-sampling oscilloscope. A 50-ohm probe should be used to minimize measurement jitter. The tolerance for this test is ± 20ps[14] (min-max) due to the tester/instrument interaction using a generic measurement method. The results are expressed as RMS.

10.4.6.1 This measurement depends on the jitter distribution being Gaussian. Reference Appendix 4 for additional detail regarding this measurement. If in the application of this method it is determined that the jitter is non-Gaussian, skip this test and make the appropriate notation on the exceptions page (Appendix 3). The following nested loop outline describes the test flow:

```
for pin = (all high speed clock pins)
  for amplitude = 3V
    for test_cycle = 10*min to min by min
      for clock_delay = 50%
        for i = 1 to 1000
meas(i) = measure the pulse width of the clock pin
under test
        end i
measured signal jitter = RMS spread of meas(1)
through meas(1000)
      end format_delay
```

14 When recording measurement data, log all measurements as they are taken from the measurement equipment and show the associated equipment tolerance as a separate entity.

end test_cycle
end amplitude
end pin
measured instrumentation jitter = RMS spread of oscilloscope trigger
(method described further in Appendix 4)
actual RMS signal jitter = measured signal jitter - measured instrumentation jitter
(via sum of squares - reference Appendix 4)

Reference load B (50 ohms to ground) should be used for this measurement.

11 Data Collection Tables

11.1 Table 1 is the data collection table. Data can be manually or automatically entered to this table as this procedure is executed, depending upon how the user chooses to implement data collection.

11.2 Table 2 is intended to contain the final conclusions or analysis results of this procedure. Data for this table is taken from Table 1. Instructions for entering data to Table 2 will be described in Section 12, Reporting and Interpretation of Results, of this procedure. Examples of OTA calculations and data entry to Table 2 are contained in Appendix 2.

NOTE 4: A blank version of Table 2 is contained in Appendix 1.

12 Reporting and Interpretation of Results

12.1 *Reporting Results* — A large amount of data will be gathered when this Test Method is executed per the requirements of this method. A subset of this data should be collected into Table 1. This table contains the minimum and maximum values for the various tests contained in this Test Method.

12.1.1 Table 2 is a summary revealing the results of this Test Method. Table 2 entries will be determined from values taken out of Table 1 as well as summations of various entries occurring in Table 2. The following is a guide to making entries to Table 2:

12.1.2 *Driver Input Timing Delay Error (Section 10.4.1)* — This value is taken from Table 1. It is the difference between the minimum and maximum values shown in Table 1 for this parameter.

12.1.3 *Driver Input Timing Cycle Jitter (Section 10.4.4)* — This value is taken from Table 1. This is the RMS values shown in Table 1 for this parameter.

12.1.4 *Driver Input Transition Time Variation (Section 10.4.3)* — This value is taken from Table 1. It is the difference between the minimum and maximum values shown in Table 1 for this parameter.

12.1.5 *Driver Input Edge Placement Accuracy* — Driver Input Edge Placement by definition is the summation of Driver Input Timing Delay Error (Section 10.4.1), Driver Input Timing Cycle Jitter (Section 10.4.4), and Driver Input Transition Time Variation (Section 10.4.3). Regardless, since Drive Input Timing Delay Error measurements defined in this method do not exclude edge transition variation and jitter this entry is simply the measurements results obtained for Drive Input Timing Delay Error Level 2 (Section 10.4.1). Enter this value into Table 2 as Driver Input Edge Placement.

12.1.6 *Compare Output Time Delay Error (Section 10.4.2)* — This value is taken from Table 1. It is the difference between the minimum and maximum values shown in Table 1 for this parameter.

12.1.7 *Compare Output Edge Placement Accuracy* — Compare Output Edge Placement will be entered into Table 2 as the same entry made for Compare Output Time Delay Error (Section 10.4.2).

12.1.8 *Drive Input to Compare Output Timing Accuracy* — Data taken from Table 1 for Section 10.3.1 results: Drive Input To Compare Output Timing Accuracy = Reference – [(Min Value + Max Value)/2]. Refer to examples in Appendix 2.

12.1.9 *Overall Timing Accuracy (OTA)* — By definition and in the general case, the OTA value is the sum of Driver Input Edge Placement Accuracy, Compare Output Edge Placement Accuracy, and Driver Input to Compare Output Timing Accuracy. Examples are provided in Appendix 2 for making this entry into Table 2.

NOTE 5: For all High Speed Clock parameters shown in Table 2: High Speed Clock Delay and High Speed Clock Transition are parameters that use the same procedures as Drive Input Timing Delay and Drive Input Transition Time Variation. High Speed Clock Delay and High Speed Clock Transition are parameters provided in this procedure to accommodate those systems that have different pin electronics for the High Speed Clock function. If the system under evaluation doesn't have a High Speed Clock function, then the steps in this procedure for all High Speed Clock Accuracy are not required. High Speed Clock Cycle Jitter and High Speed Clock Phase Jitter are reference parameters with their respective test provided in this procedure to reveal accuracy for the High Speed Clock function when that function is present.

12.1.10 *High Speed Clock Delay Error (Section 10.4.1)* — This value is taken from Table 1. It is the difference between the minimum and maximum values shown in Table 1 for this parameter.

12.1.11 *High Speed Clock Cycle Jitter (Section 10.4.5)* — This value is taken from Table 1. This is the RMS values shown in Table 1 for this parameter.

12.1.12 *High Speed Clock Transition Time Variation (Section 10.4.3)* — This value is taken from Table 1. It is the difference between the minimum and maximum values shown in Table 1 for this parameter.

12.1.13 *High Speed Clock Phase Jitter (Section 10.4.6)* — This value is taken from Table 1. This is the RMS values shown in Table 1 for this parameter.

12.1.14 *High Speed Clock Accuracy* — This parameter is for systems that have a High Speed Clock function. High Speed Clock Accuracy is simply the same entry made for High Speed Clock Delay Error. High Speed Clock Transition Time Variation, High Speed Clock Cycle Jitter, and High Speed Clock Phase Jitter are reference parameters and should be entered to the appropriate location in Table 2.

12.1.15 *Driver Input Z Timing Errors (Section 10.3.5)* — There are four Drive Input Z Timing Errors. Each value is determined in the same way and is to be entered into Table 2. This value is taken from Table 1. Data to enter here is Positive Error and Negative Error per the data in Table 1 and Equation 1, Appendix 2.

12.1.16 *Timing Linearity (Section 10.3.1)* — This value is established from Table 1. Data to enter here is Positive Error and Negative Error per the data in Table 1 and Equation 1, Appendix 2. These two values should be entered at the appropriate place in Table 2.

12.1.17 *Extended Delay (Section 10.3.4)* — This value is taken from Table 1. Data to enter here is Positive Error and Negative Error per the data in Table 1 and Equation 1, Appendix 2.

12.1.18 *Multiple Period (Section 10.3.6)* — This parameter is optional. The test method for this parameter was defined for those systems with Timing On the Fly (OTF). If the system under evaluation does not have OTF timing data entry for this parameter is not required. Else, this value is taken from Table 1. Data to enter here is Positive Error and Negative Error per the data in Table 1 and Equation 1, Appendix 2.

12.2 *Interpreting Results* — Table 2 will contain summarized data, results of the Overall Digital Timing Accuracy Analysis Method for automated test systems.

12.2.1 This dialog is intended to explain the Level 1 and Level 2 results for OTA contained in Table 2 and require reference to Figure 6, Figure 7[15], and Table 2.

12.2.2 Level 1 analysis is meant to determine a test system's net conformance to the OTA specification in an efficient manner.

12.2.3 Level 2 employs external equipment to isolate parameters that contribute to OTA. That data reveals a more detailed and accurate representation to OTA conformance. Regardless, there is a limitation at getting to OTA entirely through Level 2 data collection.

12.2.4 Level 1 and Level 2 parameters are contained in Table 2 to represent OTA (Overall Timing Accuracy). Level 1 Timing Linearity (Section 10.3.1) provides analysis for all pins under comprehensive conditions and is used to acquire the drive input to compare output error parameter. Extended Delay (Section 10.3.4) complements Timing Linearity by verifying accuracy for timing generator delays beyond the length of the test cycle, and can be (optionally) used in lieu of Section 10.3.1. These two Level 1 elements represent in part OTA. Thus, this method produces a single point representation of system OTA, per the methodology defined in this method and consistent with the definition of OTA. This is done by summing Level 2 Drive Input Edge Placement Accuracy and Compare Output Edge Placement Accuracy with Level 1 Drive Input to Compare Output Timing Accuracy.

12.2.4.1 Compare side error in this method is not fully characterized or broken out into its constituent components, per the defintion of Compare Output Edge Placement Error. This method does establish Output Timing Delay Error, and its measurement contains the jitter component. But the method does not contain a way for determining Output Compare Timing Jitter by itself.

12.2.5 Establishing OTA using only Level 2 data is not possible. Only two of the three components per the standard definition of OTA can be determined. The OTA definition states: OTA is the sum of Drive Input Edge Placement, Compare Output Edge Placement, and Drive Input to Compare Output Accuracy. Level 2 analysis will collect data for the first two error components. The Level 2 parameter not achievable is Drive Input to Compare Output Accuracy. Level 1 will determine that value.

12.2.5.1 The Drive Input to Compare Output Accuracy by definition is the difference between the average of min & max drive input delay timing and the average of min & max compare output delay timing. Values for those components are in the Level 2 data, but because there is no common reference point for these two components when the data is taken, their difference cannot be established from the data at-hand.

12.2.5.2 In summary Level 2 analysis is capable of independently determining and isolating drive input timing error and compare output timing error. But, Level 2 drive input to compare output-timing error can not be established. Analysis done in Level 1 is required

15 Additional information related to Figure 7 is contained in Appendix 2.

to establish Drive Input to Compare Output timing error. Reference Figure 6.

12.2.6 As noted, Level 1 analysis does establish drive input to compare output-timing error. But, Level 1 cannot independently determine and isolate drive input timing error from compare output timing error, as was accomplished in Level 2. What this means is if the minimum to maximum drive input to compare output timing error is established as 1ns (Level 1), the method cannot create a break down such that so much of that 1ns is input error, with the remaining part of that 1ns being the output error.

12.2.7 Table 2 data also contains other valuable components of ATE error that will assist in establishing ATE timing integrity. Tests that establish the various components of Input Z Timing error, Multiple Period Tests for on the fly timing, and for systems with a High Speed Clock function tests to determine various delay, jitter and time variation errors.

12.3 A brief word on Drive Input to Compare Output Timing Accuracy will be made. Drive Input to Compare Output Timing can be described in different ways. It is easy to think of this parameter, per the definition of this aspect of OTA (reference Figure 6), as simply the relative time difference (skew) between drive input delay timing (see SEMI G79) and compare output delay timing (see SEMI G79), for a particular machine.[16] But this parameter, once established, is not necessarily constant. For example, this parameter can change from one calibration of a machine at a particular time, to something different, as a result of a subsequent calibration of that same machine. As well, Drive Input to Compare Output error can also be considered as a machine to machine accuracy parameter, not necessarily having the same value between any two machines of the same kind.

12.3.1 Thus, on each machine and at different points in time for the same machine the Drive Input to Compare Output Timing skew can be uniquely different per machine. That difference being influenced by the various machine anomalies that contribute to machine error including the not so perfect results of a periodic edge calibration.

12.3.2 In the general case drive input to compare output as shown in Figure 6 should be thought of in the context of drive/compare edges having time variance across multiple machines or as representing edges for the same machine but having variance across multiple time intervals associated with different calibrations.

16 Both drive input delay timing and compare output delay timing values taken at center of spread. By definition center of spread is the average of min & max: (minerr + maxerr)/2.

12.3.3 Examination of the OTA definition in the context of Figure 6, that being the general case and not a single point timing evaluation, reveals that the overall timing accuracy time value is the time line indicated by "A" and the time line indicated by "B". In a single point AC timing evaluation, OTA is determined as a distribution of edges associated with time line "A" or time line "B", depending upon the relationship between the drive edge values and compare edge values (see SEMI G79) at that point in time.

13 Precision, Accuracy, and Precautions

13.1 *Precision and Accuracy* — Tolerances called-out in the various steps of this procedure are consistent with the required supplemental equipment specifications called for in this Test Procedure.

13.2 *Precautions* — A precaution is advised when executing this procedure to the letter. Unreliable execution or failures may occur as a result of ATE specification tradeoff that typically exists between minimum pulse width and drive signal amplitude. This can be especially true when operation is in conjunction with complex formats such as SBC. This condition is a result of specification limitations inherent in the system under evaluation. Be advised that failure conditions can occur for systems with inadequate minimum pulse width and/or inadequate comparator bandwidth characteristics operating this procedure at high frequencies with complex formats.

13.3 It is necessary to note that data in Table 1 for any particular test represents minimum and maximum values taken for all conditions specified for each test. Examples of these conditions are parameters such as frequency, formats, and different voltages. Thus the precaution lies in how the user interprets the minimum to maximum deltas. As an example, a minimum value can occur at a lower frequency whereas a maximum value for that test may occur at a higher (different) frequency. Be aware, deltas under broad conditions may be greater than deltas for a focused condition. This specification is defined to provide results for the broad case.

13.4 When entering your analysis results to Table 2 Single Point Overall Timing Accuracy (OTA), be advised that the Single Point OTA Result is represented only as indicated in Table 2, the sum of Drive Input to Compare Output Timing, Drive Input Timing Delay Error, and Compare Output Time Delay Error. This appears to deviate from the absolute definition of OTA in that Drive Input Transition and Drive Input Timing Cycle Jitter are not included. The method does not lend itself to making Drive Input Timing Delay Error measurements that exclude these two components. Per this method when the Drive Input Timing Delay Error measurements are made they include these two parameters. Thus, because of the measurement if included per the definition, they would be double counted.

13.5 The OTA definition used in this method does not include reference parameters shown in Table 2 such as Drive Input Z Timing Error, Extended Delay, Multiple Period (timing on the fly), and High Speed Clock measurements. These are strictly reference timing parameters. This method is not defined such that they are to be included as part of OTA. Thus the user is advised not to sum any of those items as part of the OTA value entered into Table 2.

13.6 Table 2 is labeled Single Point Overall Timing Accuracy (OTA) Results. The term “single point” is used as a reminder for the user of this document that one execution of this method on a particular ATE system does not in itself constitute an overall timing accuracy conclusion for that system. It is simply a sample of the ATE's performance at some point in time. A true assessment of an ATE's performance for overall timing accuracy requires a comprehensive analysis involving data collection over an extended period of time that goes well beyond what this method provides in one pass.

13.7 In general, regarding these precautions, the user is free to adjust the procedure and data collection according to conditions consistent with the desired objective. Regardless, if the procedure is performed under anything other than full-up broad conditions, the results must be identified as a subset or partial interoperation of a single point overall timing accuracy assessment.

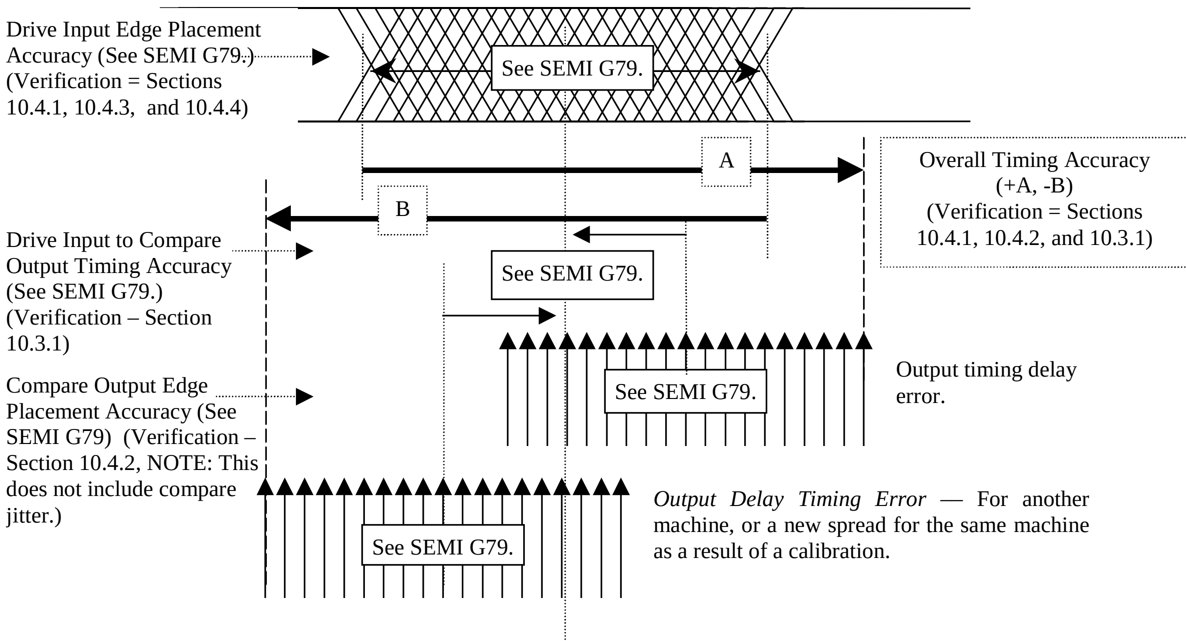
None.



For reference see the following definitions taken from SEMI G79:

7.1.1 *Input Edge Placement Accuracy* — DUT input timing error comprised of input timing delay error, input timing jitter and input transition time variation.

7.1.2 *Output Edge Placement Accuracy* — DUT output compare timing error comprised of output timing delay error and output compare timing jitter.

Output Timing Delay Error — time delay error at the detected midpoint of a 5V transition, with respect to an ideal delay (NIST traceable reference), using any pin, any delay value, any compare timing edge, window or strobe compare mode, expect H or L, positive or negative transition and any test cycle length.

Conditions:

- measured with load circuit "off" or high impedance
- delays normalized to rising edge detected by pin 1, using strobe compare format, expect H, @ 0ns
- error normalized to the average of min & max of the error distribution
- input signal: 50-ohm source, 0–5V step, > 1V/ns, inserted at a zero length interconnect on the DUT side of a standard performance board

Output Compare Timing Jitter — short term (cycle to cycle) instability using any pin, any compare timing edge, window or strobe compare mode, expect H or L. (NOTE: This document does not define a method for Output Compare Timing Jitter.)

Conditions:

- error expressed as RMS value
- physical reference point is a zero length interconnect on the DUT side of a standard performance board
- jitter referenced to an independent synchronous trigger

7.1.3 *Input to Output Timing Accuracy* — relative time difference between the input delay timing and output delay timing.

NOTE 6: This is a generic example of the data table needed to gather the data values for this timing analysis procedure. The actual number of table entries will depend upon the number of tester pins under evaluation. The pins to be tested are represented by the designation “m” to “n”. For Level 1 the application program is expected to fill in the minimum and maximum measurements made for each pin and specified condition. For Level 2 the user will fill-in these data values via manual entry, unless the application and implementation method employ automated/robotic operation.

A2-1 Examples

NOTE 1: This appendix contains Figures A2-1, A2-2, A2-3, and A2-4 created for this method as examples. The purpose of these examples is to show that Drive Input To Compare Output Error (Accuracy) can be determined. Establishing this value requires that two edge timing values be detected: MIN DRIVE VALUE: the earliest occurrence the drive edges with the latest compare edge. That is also referred to here as FIRST PASS. MAX DRIVE VALUE: the latest occurrence of the drive edges with the earliest compare edge. That is also referred to here as LAST FAIL.

NOTE 2: Timing Linearity Test 10.3.1 can provide these values. Examples in this appendix will also show data entry to Table 2 for OTA calculation.

A2-1.1 *Maximum Drive Value and Minimum Drive Value* — To follow this analysis you can refer to the example in Figure 7. In this example drive error and compare error are each 100ps.

NOTE 3: Figures A2-1, A2-2, A2-3, and A2-4 are equivalent and represent complementary examples for the cases where drive error does not have the same error value as compare error.

A2-1.2 Minimum Drive Value is determined by first assuming that all compare edges are programmed at 0ns. You must then take into account the drive to compare error, in this example that value is –50ps (note the sign indicating the shift is in the negative direction). Add the drive to compare error to the compare programming value. That means that the average (mean) compare edge can be thought of as actually occurring at –50ps (versus the programmed value of 0ns). Per this example the compare error is ± 100ps, which means the latest compare edge would occur at + 50ps (–50ps + 100ps). Since the driver edge error is also ± 100ps and is programmed to the reference value of 1000ps, the earliest drive edge occurs at 900ps (1000ps minus 100ps). The MIN DRIVE VALUE is then whatever programming value is needed to get the latest compare edge (at + 50ps) to line up with the earliest drive edge (at 900ps). In this case that's 850ps (the difference between 50ps and 900ps). This value of 850ps is also referred to at the FIRST PASS.

A2-1.3 The same analysis applies when determining Max Drive Value. First assume all compare edges are programmed to 0ns. The drive to compare error must be added-in, in this case –50ps. That puts the mean programmed compare edge at –50ps. Taking into account the compare edge error of 100ps the earliest compare edge would occur at –150ps. The drive edges are programmed to 1000ps. Thus the latest drive edge occurs at 1100ps when the 100ps drive edge error is taken onto account. To get the earliest compare edge to line up with the latest drive edge 1250ps of delay would need to be programmed (the difference between 1100ps and –150ps). This value of 1250ps is referred to as the LAST FAIL.

A2-1.4 *Drive to Compare Edge Error* — By definition DRIVE TO COMPARE EDGE ERROR is the relative time difference between the drive (input) edge error and compare (output) edge error distributions. All drive edges in Level 1 are detected in parallel in pairs. Once the minimum and maximum values of drive edge are determined per procedure 10.3.1 (illustrated in Figures A2-1 through A2-4) determination of drive to compare edge error can be established. As per these examples (Figures 7 and A2-1 through A2-4) the drive to compare edge error is calculated as the reference value minus the average of min and max error values:

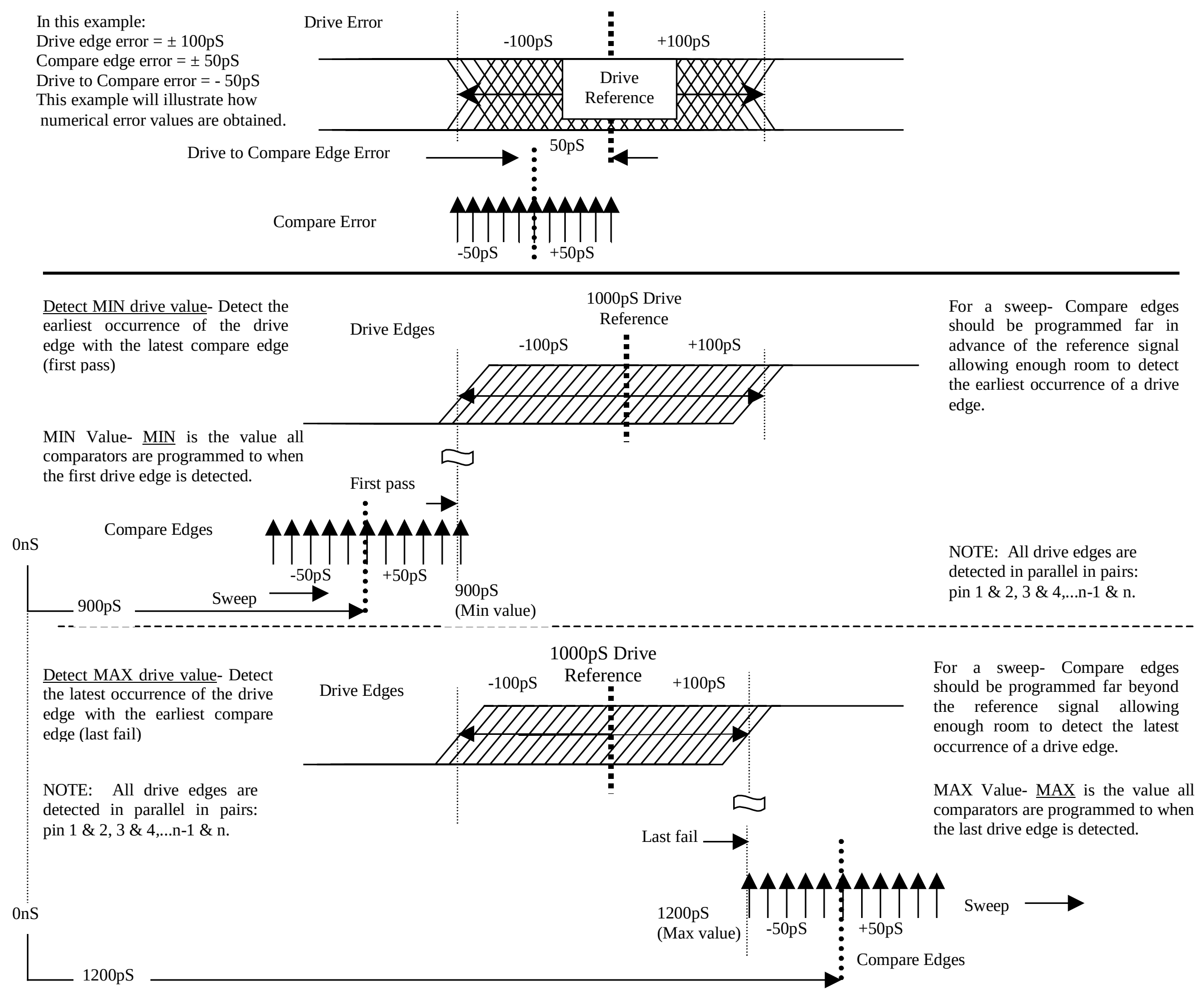
Drive to Compare Error =
Reference-[Min Value + Max Value)/2]

A2-1.5 *Distinguishing Drive and Compare Edge Error Uniquely Is Not Possible with Level 1 Tests* — The user is cautioned that even though drive to compare edge error is known, per this method it is still not possible to distinguish Level 1 drive input error from compare output error. The key to this shortcoming lies in observation of examples shown in Figures A2-1 thorough A2-4. These examples have drive and compare edge error values that are not the same value. That is, drive error is either much greater that compare edge error, or vice versa. In each example drive to compare edge error is established. To establish the point that drive input error cannot be distinguished from compare output error per level 1, the user is asked to look at Figures A2-1 and A2-2. In these two examples it is assumed that the drive error and compare error are different by a factor of two. Because of limited visibility per the level 1 approach it is not possible to determine that the drive error is ± 100ps and the compare error is ± 50ps (example in Figure A2-1), or vice versa. All that can be established is that the positive error is 200ps and the negative error is 100ps. Level 2 tests are required to determine drive input timing error and compare output timing error.

A2-1.6 The same rationale applies for the examples in Figure A2-3 and A2-4 where one component of error is assumed to be 200ps and the other is 100ps, with a 50ps drive to compare error. The drive to compare edge error is determined, but again establishing a unique value for drive or a unique value compare error is not possible in Level 1. All that is known per Level 1 analysis is that the positive error is 350ps and the negative error is 250ps.

A2-1.4 *Positive and Negative Error* — EQUATION 1: Per the examples in this Appendix and data taken out of Table 1:

Positive Error = *Reference* - *Max Value*
Negative Error = *Reference* - *Min Value*



TIMING RELATIONSHIPS, DEFINITIONS & EXAMPLE RESULTS

DEFINITIONS-

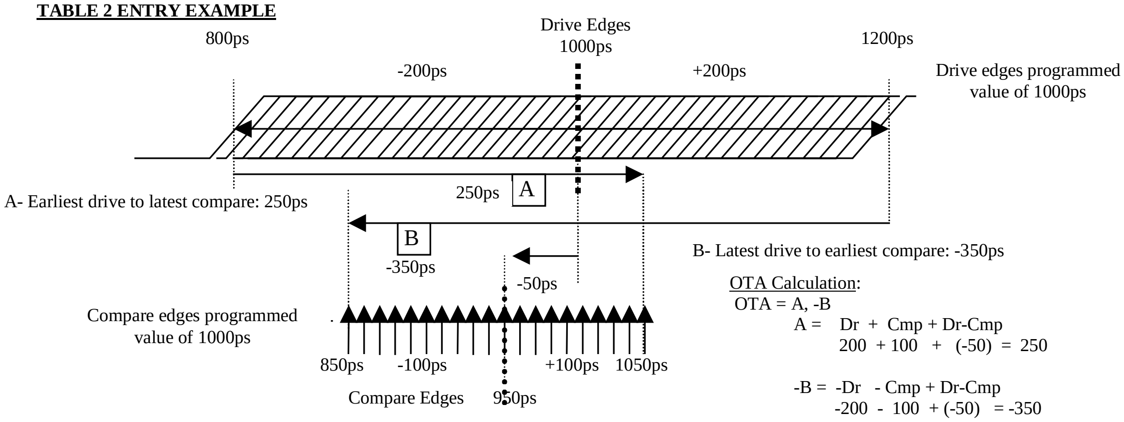
The user of the method is advised to read Section 13, Precautions before filling in this table.

OTA DATA CALCULATION and TABLE 2 ENTRY EXAMPLE



OTA Calculation:
OTA = A, -B
A = Dr + Cmp + Dr-Cmp
200 + 100 + (-50) = 250

-B = -Dr - Cmp + Dr-Cmp
-200 - 100 + (-50) = -350

OTA = 250ps, -350ps

Example A2-6 Test Method Summary for Showing Data Entry to Table 2 for OTA Calculation

LEVEL 1		Single Point Overall Timing Accuracy (OTA) Results *Data to enter here is: A = Dr (item 2) + Cmp (item 3) + Dr-Cmp (item 1)* *-B = -Dr (item 2) - Cmp (item 3) + Dr-Cmp (item 1).* **+350ps, –250ps**			LEVEL 2

A4-1 Jitter Measurement

A4-1.1 If a jitter measurement described here is to be statistically correct the jitter variation in the signal being measured must be Gausian. The measured jitter in this method will be represented as one standard deviation (sigma) of the Gausian distribution, referred to here as the RMS jitter value.

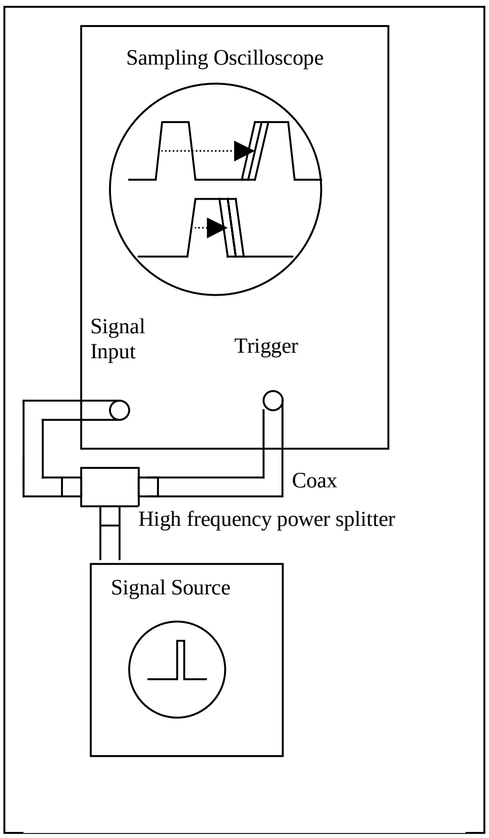

Figure A4-1
Signal Jitter Measurement

A4-1.2 The signal being measured will have some amount of jitter. The instrumentation used to measure the jitter will also have some amount of jitter. To accurately measure the jitter of a periodic signal the jitter component of the instrumentation must be accounted for and subtracted from the signal being measured.

A4-1.3 Two jitter measurements are required. A jitter measurement will be made on the signal of interest. A second jitter measurement will be made to determine the instrumentation jitter. Instrumentation jitter will be subtracted from the signal measurement to obtain the most accurate representation of signal jitter.

A4-1.4 A sampling oscilloscope will have an inherent delay, typically on the order of 20ns. This represents the time difference from the time the oscilloscope is triggered to the time when an input signal can be viewed. The key to extracting the jitter of the measurement instrumentation is providing a setup that allows viewing the trigger on the oscilloscope display. This is accomplished by delaying the oscilloscope trigger to an input channel.

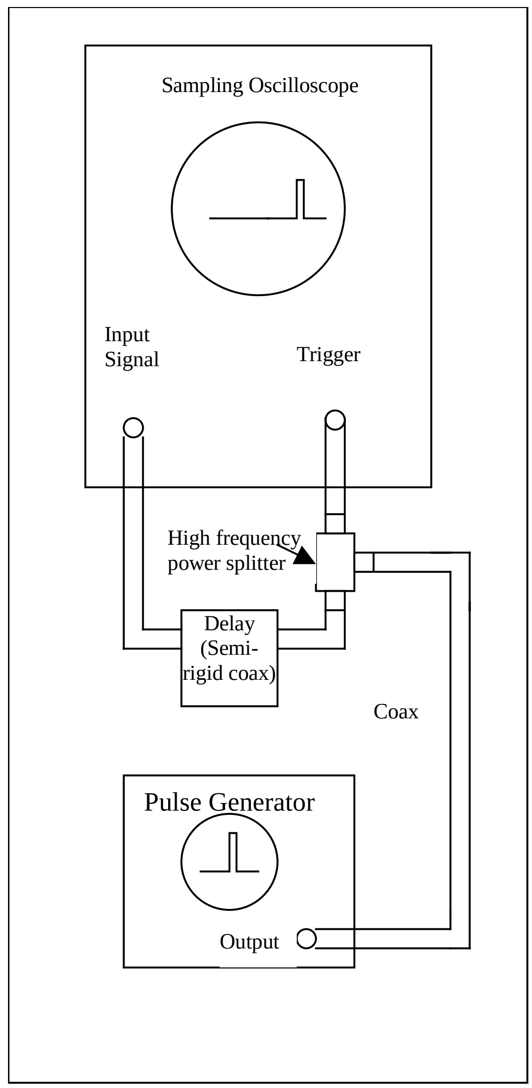

Figure A4-2
Measuring Instrumentation Jitter

A4-1.4.1 The amount of delay to the input channel must be greater than the inherent delay of the oscilloscope.

A4-1.5 A high bandwidth-sampling oscilloscope with statistical calculation capability is recommended. In addition, when making low jitter measurements high quality RF connectors and cables will be required. A setup similar to that shown in Figure A4-2 is adequate for extracting instrumentation jitter.

A4-1.6 Using semi-rigid coax for the delay will minimize loss of signal. The pulse generator should be set to low frequency to maximize the pulse width. A period of 10MHz with a 50ns pulse width is adequate for an oscilloscope with an inherent delay of 20ns . The semi-rigid coax length should be chosen to have a delay slightly larger than the inherent delay of the oscilloscope. The proper amount of delay allows viewing the trigger signal with minimal oscilloscope horizontal delay.

A4-2 *Procedure*

A4-2.1 A signal measurement will be made as indicated in Figure A4-1. The semi-rigid coax (delay) is not used, but the power splitter output will be connected to the oscilloscope input. As well, the input to the power splitter is connected to the signal being measured. The scope is triggered from the input signal, and the signal being viewed is delayed from the trigger by an amount equal to the inherent delay of the oscilloscope. This measurement step provides a value referred to here as MEASURED RMS SIGNAL JITTER, MS.[17]

A4-2.2 An instrumentation jitter measurement is then made as indicated in Figure A4-2. Per this arrangement the signal being displayed is the same signal that triggered the oscilloscope. That connection scheme cannot produce any signal jitter between the trigger and the signal being viewed; thus any jitter shown on the oscilloscope display represents instrumentation jitter. This measurement step provides a value referred to here as MEASURED RMS INSTRUMENTATION JITTER, MI.

A4-2.3 Since the signal jitter being measured is Gausian, the sum of squares relationship is used to subtract out the instrumentation jitter, and thus obtain ACTUAL RMS SIGNAL JITTER, AS.

$$MS = (MI^2 + AS^2)^{1/2}$$

MS- Measured RMS signal jitter.

MI- Measured RMS instrumentation jitter.

AS- Actual RMS signal jitter.

17 Use of a loop-through sampling head is an alternative method for making this measurement.

A4-3 *Example*

A4-3.1 Measured RMS signal jitter MS, the signal being measured, results in a 10ps measurement.

A4-3.2 Measured RMS instrumentation jitter MI, the jitter of the measurement setup, results in a 5ps measurement.

A4-3.3 The actual RMS signal jitter AS is determined from the relationship:

$$MS = MI^2 + AS^2)^{1/2}$$

and calculates to be:

$$10^2 = 5^2 + AS^2$$

$$100 = 25 + AS^2$$

$$75 = AS^2$$

$$75^{1/2} = AS$$

8.66ps = AS (actual RMS signal jitter)

Since the jitter is Gaussian, the max value of jitter is approximately equal to 5 or 6 times the RMS value of the jitter.

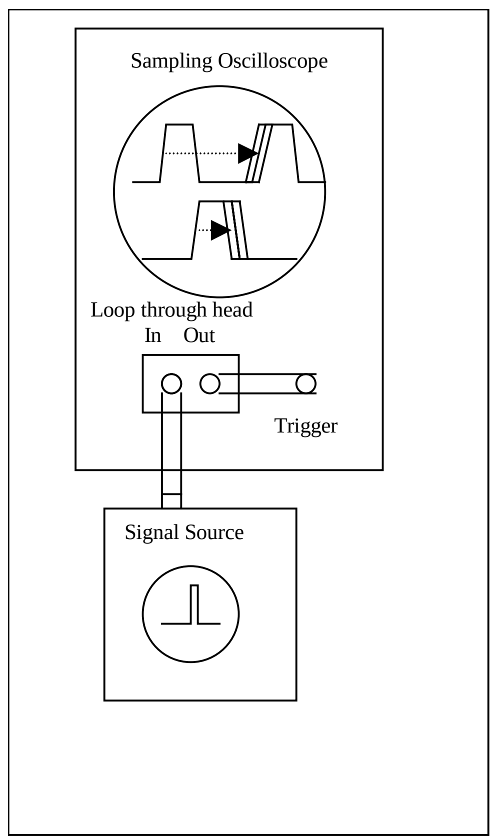

Figure A4-3
Use of a Loop-Through Sampling Head

A4.4 *Use of a Loop-Through Sampling Head*

A4-4.1 This is an alternate approach to measured RMS signal jitter. The input signal is routed through the loop-through sampling head where it is sampled and sent to the output of the sampling head. The head output is connected to the oscilloscope trigger. (See Figure A4-3.)

A4-4.2 *What is Observed When Making MS And MI Measurements* — This dialog is meant to provide further clarification for making jitter measurements. This is an example that applies to a jitter measurement using an oscilloscope with an inherent oscilloscope delay of 20ns. The signal frequency is 100MHz (period of 10ns). The semi-rigid coax delay is set to the inherent oscilloscope delay of 20ns.

A4-4.3 *Measured RMS Signal Jitter, MS* — For the MS measurement the observed edge occurs subsequent to the edge that triggered the oscilloscope:

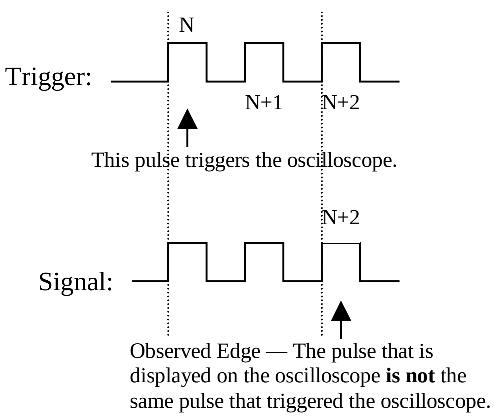

Figure A4-4
Measured RMS Signal Jitter, MS

A4-4.4 The observed edge depends upon the signal frequency; thus what is displayed is subsequent to the trigger pulse permitting signal jitter to be observed.

A4-4.5 *Measured RMS Instrumentation Jitter, MI* — For the MI measurement the observed edge is the same edge that triggered the oscilloscope.

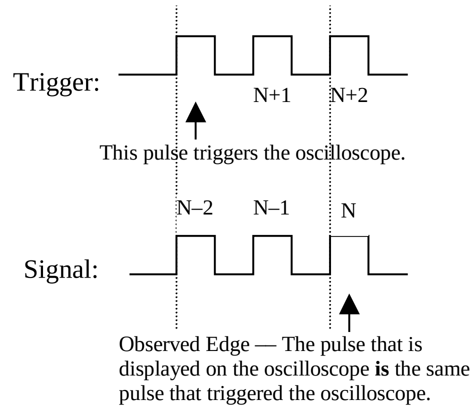

Figure A4-5
Measured RMS Instrumentation Jitter, MI

A4-4.6 There is no repetitive aspect of the signal, thus whatever jitter you observe is strictly instrumentation jitter.

A4-4.7 *Summary* — Jitter is only observable for a periodic signal or repetitive edge. Thus when MS measurements are made signal jitter is observed because a subsequent or repetitive signal is displayed (in addition to instrumentation jitter). When MI measurements are made the input signal is delayed such that you see the same edge that trigger the oscilloscope. That creates a non-repetitive or non-periodic occurrence of the observed signal, thus the jitter observed is strictly due to the instrumentation.

NOTICE: SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI G81-1101
SPECIFICATION FOR MAP DATA ITEMS

This specification was technically approved by the Global Automated Test Equipment Committee and is the direct responsibility of the Japanese Test Committee. Current edition approved by the North American Regional Standards Committee on August 27, 2001. Initially available at www.semi.org September 2001; to be published November 2001. Originally published October 2000.

1 Purpose

1.1 This document describes the data items that relate to electronic substrate mapping.

2 Scope

2.1 This document applies only to substrate map data items.

2.2 This document does not address the transmission, file naming conventions, storage or archiving of substrate maps.

2.3 The specification of which data items are optional and which are required is not specified in this document.

2.4 The size of each data item described in this document is maximum size. The actual size may be further restricted by an application document.

2.5 The order of the data items is not restricted in this document. The order of the data items may be restricted by an application document.

2.6 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 There are no known limitations within the defined scope.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI E5 — SEMI Equipment Communications Standard 2 Message Content (SECS-II)

SEMI T9 — Specification for Marking of Metal Lead-Frame Strips with a Two-Dimensional Data Matrix Code Symbol

4.2 *IEEE Standards*[1]

IEEE 754-1985 — IEEE Standard for Binary Floating–Point Arithmetic

NOTE 1: Unless otherwise indicated, all documents cited shall be the latest published versions.

5 Terminology

5.1 *Definitions*

5.1.1 *bottom side* — the bottom side of the substrate as defined in the corresponding Appendix (Appendix 1, 2, or 3).

5.1.2 *device* — the unit to which the device status code in the map is assigned including, but not limited to: die, multi-chip modules and packages.

5.1.3 *map* — a two-dimensional array of bin codes derived from electrical test data of a substrate including, but not limited to: wafer, tray, strip, or tape.

5.1.4 *substrate* — any carrier of a two-dimensional array of devices including, but not limited to: wafers, trays, strips, tape, panels, or boards.

5.1.5 *top side* — the top side of the substrate as defined in the corresponding Appendix for that substrate (Appendix 1, 2, or 3).

6 Requirements

6.1 This document does not define format of each data item specified in the following chapter. In order to implement this specification, it requires standardized and/or specific format definition documents. Standardized format definition documents are those generic, application specific or equipment specific specification, supplied by SEMI. They may be format specification, static file specification or communication specification, e.g. SEMI E5. Specific format definition documents may de defined by supplier and user.

1 Institute of Electrical and Electronics Engineers, IEEE Operations Center, 445 Hoes Lane, P.O. Box 1331, Piscataway, New Jersey 08855-1331, USA. Telephone: 732.981.0060; Fax: 732.981.1721

6.2 Also this document does not define communication protocol at all. If an implementation requires transfer data items defined in the following chapter, it is necessary to prepare a custom communication protocol document or to comply with the appropriate SEMI communication standards.

6.3 This document places no special requirements on the transmission, file naming conventions, storage, or archiving of substrate maps.

7 Description

7.1 The substrate map data item specifications defined in this document are shown in Table 2. The columns in this table are described in the following sections.

7.1.1 *Item Name Column* — the name by which the data item is referenced.

7.1.2 *Data Type Column* — the type of the data as defined in Table 1.

Table 1 Data Types and Sizes

Type	*Size*	*Definition*
String	0–32767	A string of ASCII characters from zero to “Size” characters in length.
Integer	1,2,4	An integer value that may be represented by “Size” bytes. E.g., if Size = 2 then the value may be –32768 to 32767.
Float	4	IEEE single-precision 32-bit floating point type [IEEE 754-1985]

7.1.3 *Size Column* — the maximum number of characters that may be used to represent the data.

7.1.4 *Description Column* — describes what the data item is and what value restrictions it has.

7.2 *Coordinate System Conventions*

7.2.1 Whenever reference is made to rows, columns, X or Y they are defined as follows.

7.2.2 The X axis is the horizontal axis from left to right when the substrate is rotated according to [Orientation] in Table 2. Columns increase along the X axis. Column zero is the column just before the left (or right, depending on OriginLocation) column containing measured devices.

7.2.3 The Y axis is the vertical axis from bottom to top when the substrate is rotated according to [Orientation] in Table 2. Rows increase along the Y axis. Row zero is the row just before the extreme top (or bottom depending on OriginLocation) row containing measured devices.

7.2.4 Columns increase along the X-axis. Rows increase along the Y-axis.

Table 2 Substrate Map Data Items

Item Name	*Data Type*	*Size*	*Description*
FormatRevision	String	256	Specifies the exact name and revision of the format used to represent substrate map data. This field can be used by a parser to automatically determine the format of the remaining substrate map data.
ProductId	String	256	Product identifier
LotId	String	32	Production lot identifier for this data
Orientation	Integer	2	The orientation of the substrate in relation to the map data. This variable will increase in the right (clockwise) direction from 0°. This item may be used to specify that the map data be rotated. Since the map data is rectangular, only the values 0, 90, 180, and 270 are allowed in that case.
WaferSize	Integer	2	Diameter of Wafer in millimeters.
DeviceSizeX	Float	4	Device size on X axis in microns
DeviceSizeY	Float	4	Device size on Y axis in microns
StepSizeX	Float	4	The distance in microns from a reference point on one device to the same reference point on the adjacent device in the X direction. StepSizeX – DeviceSizeX is equal to the “street” width between device in the X direction.

Item Name	*Data Type*	*Size*	*Description*
StepSizeY	Float	4	The distance in microns from a reference point on one device to the same reference point on the adjacent device in the Y direction. StepSizeY – DeviceSizeY is equal to the "street" width between device in the Y direction.
WaferId	String	32	A character code that may be printed or encoded on the substrate, which uniquely identifies the substrate, and can be used to correlate the map with physical substrate.
FrameId	String	32	A character code that may be printed or encoded on the substrate, which uniquely identifies the substrate, and can be used to correlate the map with physical substrate.
StripId	String	32	A character code that may be printed or encoded on the substrate, which uniquely identifies the substrate, and can be used to correlate the map with physical substrate.
TrayId	String	32	A character code that may be printed or encoded on the substrate, which uniquely identifies the substrate, and can be used to correlate the map with physical substrate.
CassetteId	String	32	A character code that may be printed or encoded on the substrate carrier, which uniquely identifies the substrate carrier.
MagazineId	String	32	A character code that may be printed or encoded on the substrate carrier, which uniquely identifies the substrate carrier.
Rows	Integer	2	The number of rows of (measured) device matrix on substrate, that is the number of devices on the Y-axis of the map data. It is required if the type of the map data is simple array structure.
Columns	Integer	2	The number of columns of (measured) device matrix on substrate, that is the number of devices on the X-axis of the map data. It is required if the type of the map data is simple array structure.
MapType	String	16	Possible variations of data structure, one of which is to be chosen for passing map data. This document allows formats of the three types shown below. [MapType] = 'Row': Row/Column Format Expression using the coordinate showing the head of a row as well as the number of devices in the row and the bin data of the relevant row. Each bin data is attached in succession to each row. Example: X, Y, N, BIN, BIN, BIN, ..., BIN (N: Number of devices) [MapType] ='Array': Array Format All of a substrate's bin data is expressed in a one-dimensional array form. Left to right and top down substrate map data will be set in a one-dimensional array. Example: BIN, BIN, BIN, ... [MapType] = 'Device': Coordinate Format Expressed by XY coordinates of each device on a substrate as well as bin data. Even when using this format, to prevent omission of data, it is best to set bin data for all devices tested in front end processing. Example: X, Y, BIN, ..., X, Y, BIN The MAP coordinates set here are values for the state with the substrate orientation flat rotated to the angle given by [Orientation]. Appendix 1 contains diagrams that illustrate each [MapType]. NOTE: MAP coordinates can also be negative values.
HeadingDeviceX	Integer	2	X coordinate of the heading device of a row in the map data. This item is used when [MapType] = 'Row'
HeadingDeviceY	Integer	2	Y coordinate of the heading device of a row in the map data. This item is used when [MapType] = 'Row'
DeviceRow	Integer	2	Number of the devices on a row in the map data. This item is used when [MapType] = 'Row'
DeviceX	Integer	2	X coordinate of the device in the map data. This item is used when [MapType] = 'Device'
DeviceY	Integer	2	Y coordinate of the device in the map data. This item is used when [MapType] = 'Device'

Item Name	*Data Type*	*Size*	*Description*
BinType	String	16	The format in which the bin code for each device will be represented in the [Map]. The choices are as follows: [BinType]='Ascii': Single ASCII character [BinType]='Decimal': 3 digit integer from 000 to 255 [BinType]='HexaDecimal': 2 digit Hexadecimal value from 00 to FF NOTE 1: For readability when [BinType]='Decimal' there must be spaces added between each device and each row of devices should be on a new line. NOTE 2: When [BinType] = 'Ascii' or 'Hexadecimal' there must not be spaces between each device and for readability, each row should be on a new line.
ReferenceDeviceX	Integer	2	X coordinate of the reference device to align device matrix on physical substrate with the map data
ReferenceDeviceY	Integer	2	Y coordinate of the reference device to align device matrix on physical substrate with the map data
RefDevicePosX	Float	4	Offset in µm of the center of a reference device in the X-direction from the center of substrate.
RefDevicePosY	Float	4	Offset in µm of the center of a reference device in the Y-direction from the center of substrate.
MapName	String	32	A name that describes the purpose of the bin codes in the map. Possible examples include: "CellStatus", "DefectCode", "MarkGrade", "PackageGrade", "SortGrade".
MapVersion	String	32	The version is used to distinguish between multiple versions of maps for the same substrate with the same MapName.
BinCode	Integer	1	A bin category from 0 to 255, other that the value assigned to [NullBin], that may be assigned to a device. It should be represented according to [BinType]. NOTE: BinCode and NullBin may take on values from 0 to 255 is represented as Ascii, Decimal, Hexadecimal, or Binary, according to BinType. See definition of BinType for more information.
BinCount	Integer	4	The number of devices on the substrate with the specified [BinCode]
BinQuality	String	16	Describes the quality of the specified [BinCode]. The following values are reserved for the data item: "Pass" – Indicates a quality that has commercial value "Fail" – Indicates a quality that does not have commercial value Other values defined by an application.
BinDescription	String	256	A description of the specified [BinCode], e.g. "100MHz".
NullBin	Integer	1	Code to indicate no device or not measured device in [Data]. It should be represented according to [BinType].
SupplierName	String	256	Name of the supplier of the substrate.
OriginLocation	Integer	1	Coordinate system on substrate to address devices. Location of the datum point or the origin of the coordinates shall be one of the following: 0 = Center device* – top side 1 = Upper right – top side 2 = Upper left – top side 3 = Lower left – top side** 4 = Lower right – top side 5 = Center device* – bottom side 6 = Upper right – bottom side 7 = Upper left – bottom side 8 = Lower left – bottom side 9 = Lower right – bottom side * Center device is X=(row count+1), Y=(column count+1)/2. ** Default value is 3 (=Lower left – top side) if this item is not present
CreateDate	String	16	Date and time when the map data is acquired: formatted as YYYYMMDDhhmmsscc (year-month-date-hour-minute-second-centisecond)
Status	String	16	Status of map data supplying process or preceding process.
Label	String	256	Name of a special parameter

Item Name	*Data Type*	*Size*	*Description*
SupplierValue	String	16	Value of a special parameter

NOTE 1: A set of above items is prepared for each single substrate to make it possible to consolidate more than one lot in a cassette.

APPENDIX 2
STRIP MAP

NOTE: The material in this appendix is an official part of SEMI G81 and was approved by full letter ballot procedures on August 27, 2001.

A2-1 This appendix shows how the map data items may be applied to strips as well as some additional information specific to this substrate type.

A2-2 The StripID shall follow the SEMI T9 specification, when applicable, or may be user definable by the factory.

A2-3 For any given process there must be a way to ensure correct orientation of the strip. The end user is responsible for providing a master manufacturing drawing showing the top side of the strip. This drawing must show any special markings or patterns that are needed to reliably flip and rotate a physical strip until it is oriented the same as the drawing. Figure A2-1 defines what is meant by top side and hence bottom side. It also defines what is meant by upper, lower and left and right.

A2-4 Each strip type will have a factory defined value for OriginLocation. This is the origin reference for the row 1, column 1 location on the strip. The factory origin, OriginLocation is selected as one of four corners by the factory host system. The row and column index will be referenced from the selected reference. This information will be provided to the equipment by the host in each strip map download scenario.

1 = Upper right (UR) top side

2 = Upper left (UL) top side

3 = Lower left (LL) top side

4 = Lower right (LR) top side

6 = Upper right (UR) bottom side

7 = Upper left (UL) bottom side

8 = Lower left (LL) bottom side

9 = Lower right (LR) bottom side

Factory Origin Settings

APPENDIX 3
TRAY MAP ORIENTATION

NOTE: The material in this appendix is an official part of SEMI G81 and was approved by full letter ballot procedures on August 27, 2001.

A3-1 This appendix shows how the map data items may be applied to JEDEC trays as well as some additional information specific to this substrate type.

A3-2 The X-axis (Column) is assigned to the long axis of the JEDEC tray; the Y-axis (Row) is assigned to the short axis of the tray. This corresponds to Cartesian coordinate “1” (in this way all coordinate positions can be expressed in positive integer values). For the origin of the tray, the pocket nearest the bevel (at the bottom left corner of the tray in Figure A3-1 below) is defined as coordinate location 0,0. (Row/Column).

A3-3 The following values for OriginLocation apply to the JEDEC tray:

1 = Upper right (UR) top side

2 = Upper left (UL) top side

3 = Lower left (LL) top side

4 = Lower right (LR) top side

SEMI G82-0301^E
PROVISIONAL SPECIFICATION FOR 300 mm LOAD PORT FOR FRAME CASSETTES IN BACKEND PROCESS

This specification was technically approved by the Global Assembly & Packaging Committee and is the direct responsibility of the Japanese Packaging Committee. Current edition approved by the Japanese Regional Standards Committee on December 1, 2000. Initially available at www.semi.org December 2001, to be published March 2002.

E This document was editorially modified in November 2001 to correct a cosmetic error. Changes were made to Figure 2.

1 Purpose

1.1 This specification defines dimensional requirements for the load port of frame cassette for 300 mm wafer in backend process equipment. It is intended to promote a uniform physical interface between equipment and the factory, to facilitate the use of automated frame cassette transport systems, and/or to meet ergonomic requirements for manually loaded equipment.

2 Scope

2.1 This is a provisional standard covering equipment for 300 mm frame cassette only. The provisional status is dictated by the immaturity of designs for 300 mm equipment and additional specifications which are not defined yet.

2.2 These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This standard is not intended for use in backend except frame cassette for 300 mm wafers. This standard does not address direct loading/unloading of vacuum load locks. Requirements of such interfaces may differ from those in this document.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI E15 — Specification for Tool Load Port

SEMI E15.1 — Specification for 300 mm Load Port

SEMI E57 — Mechanical Specification for kinematic Couplings Used to Align and Support 300 mm Wafer Carriers

SEMI E64 — Specification for 300 mm Cart to SEMI E15.1 Docking Interface Port

SEMI G77 — Specification for Frame Cassette for 300 mm Wafers

5 Terminology

5.1 Please see SEMI G77 for definitions of the following terms used in this specification:

5.1.1 *bilateral datum plane*

5.1.2 *conveyor rails*

5.1.3 *facial datum plane*

5.1.4 *frame cassette*

5.1.5 *horizontal datum plane*

5.1.6 *tape frame*

5.2 Please see SEMI E15 for definitions of the following terms used in this specification:

5.2.1 *load depth*

5.2.2 *load face plane*

5.2.3 *load height*

5.2.4 *load port*

5.2.5 *spacing*

5.2.6 *tool*

5.3 *frame cassette centroid* — a datum representing the theoretical location of the center of a stack of tape frames in the frame cassette.

6 Ordering Information

6.1 The following items require communication between the tool supplier and user and shall be included in any request for quotation or purchase order:

6.1.1 If the tool has multiple load ports, provide the spacing, S, between frame cassette centroids (see SEMI E15).

6.1.2 Specify what frame cassette (e.g. optional composition, see SEMI G77) is to be accommodated by the load port (see SEMI E15).

7 Requirements

7.1 The dimensional requirements for the load port are given in Table 1 with reference to the figures of this document. Although the frame cassette transport systems shown in these figures appear similar to overhead monorails, they are intended to represent any type of transport system (AGV, PGV, conveyor, overhead track, etc.).

7.2 The dimensional requirements for the placement of the frame cassette on the load port are given in Table 1 with reference to the figures of this document.

7.3 The tape frames are to be oriented horizontally at the time they are placed on the load port.

7.3.1 The frame cassette shall be loaded and unloaded with its front parallel to and away from the load face plane (see Figure 1).

7.4 Dimension H is nominally 900 mm, fully adjustable at installation over the range of 890 to 910 mm. The precision with which the load port height must be maintained is dictated by the needs of the frame cassette delivery system.

7.5 The load port must nominally be at 900 mm, and it must be open from above to facilitate automatic frame cassette delivery from an overhead transport system. The open volume required for vertical delivery is defined by a projection of the load port area, including the area required for C1 and C2 clearances, projected upward to the top of the tool. Note that this condition need only be met when the tool is being loaded. For example, the load port may be formed by a surface that extends outward during loading to provide overhead access.

7.6 As shown in Figure 2, the maximum allowable height of an obstruction on the load port over which the frame cassette must be lifted (before being set down on the kinematic couplings) is H1. Examples of such obstructions include alignment devices and identification tag readers as well as the kinematic couplings themselves. Below H1 above the horizontal datum plane, clearances C1 and C2 no longer apply.

7.6.1 Two exclusion volumes on the left and right side of the load port must also be kept clear so that fork lifts or conveyors may be used. Each exclusion volume extends from the load face plane to D0 beyond the facial datum plane and extends H0 below the horizontal datum plane between W1 and W2 from the bilateral datum plane.

7.6.2 The load port that advances the frame cassette from the undocked position (where the frame cassette is initially delivered to the load port) to the docked position (where the frame cassette is ready for frame extraction or insertion) must reserve an exclusion volume that is intended for (but not limited to) containing automated units that read or write to an ID tag on the rear of the frame cassette in the undocked position (where the frame cassette is initially delivered to the load port). If no reader/writer unit is installed, the exclusion volume may be covered by a panel.

NOTE 1: This section is incomplete and requirements will be added to the standard once the requirements and dimensions have been fully defined.

7.7 Clearances C1 and C2 are defined with respect to the maximum dimensions of the frame cassette (see SEMI G77). To prevent interference with overhead transport systems on the same or adjacent load port, it is recommended that floor-based transport vehicles do not exceed clearances C1 and C2 when picking up or placing the frame cassette on the load port.

7.8 Dimension S specifies the recommended minimum spacing between frame cassette centroids. In any case, if S violates C1, then C1 takes precedence.

7.9 To add clearance for overhead frame cassette transport, no part of the tool in front of the plane defined by C2 may be higher than H2 from the floor. The volume below H2 may contain the frame cassette stored in an internal buffer by the tool.

7.10 The load port must provide the option to use the conveyor rails for frame cassette loading. At the time of frame cassette transfer, the conveyor rails must be positioned at HC3 as shown in Figure 2. When not in use, the conveyor rails must be lowered below the fork lift exclusion zone.

SEMI E1.9 — Provisional Mechanical Specification for Cassettes Used to Transport and Store 300 mm Wafers

SEMI E47.1 — Provisional Mechanical Specification for Boxes and Pods Used to Transport and Store 300 mm Wafers

SEMI E72 — Specification and Guide for 300 mm Equipment Footprint, Height, and Weight

SEMI G74 — Specification for Tape Frame for 300 mm Wafers

Table 1 Dimensional Requirements for 300 mm Load Port

Dimension	*Application*	*Value, mm (in.)*	*Notes*
C1	minimum	75 (3.0)	
C2	minimum	30 (1.2)	
D	range	250^{+0}_{-10} $(9.8^{+0}_{-0.4})$	
D0	minimum	110 (4.33)	
H	nominal	900 (35.4)	1
H0	minimum	15 (0.59)	
H1	maximum	25 (1.0)	
H2	maximum	2600 (102.4)	
HC3	range	$32^{+2.0}_{-0}$ $(1.26^{+0.1}_{-0})$	2
S	minimum	482 (19.0)	3
		555 (21.9)	4
W1	maximum	130 (5.12)	
W2	minimum	205 (8.07)	

NOTE 1: This value is ergonomically compatible with the proposed 13 frame cassette and may not be ergonomically compatible with the proposed 25 frame cassette. The proposed 25 frame cassette may require assisted loading. H to be fully adjustable at installation over the range of 890 to 910 mm (35 to 35.8 inches).

NOTE 2: To avoid confusion, HC3 is used instead of H3 because H3 stands for another dimension in SEMI E15.1.

NOTE 3: Frame cassette (see SEMI G77) without manual side handles

NOTE 4: Frame cassette (see SEMI G77) with manual side handles

9 Table 1 Dimensions Definition

9.1 See SEMI E15 for definitions of the following terms used in this specification:

9.1.1 C1

9.1.2 C2

9.1.3 H

9.1.4 H1

9.1.5 S

9.2 *D* — allowable load depth to frame cassette centroid.

9.3 *D0* — minimum rear clearance of equipment boundary below H1 from facial datum plane.

9.4 *H0* — minimum height from the bottom of equipment boundary below H1 to horizontal datum plane.

9.5 *H2* — maximum overhead track clearance from the floor.

9.6 *HC3* — allowable height of conveyor rail from horizontal datum plane.

9.7 *W1* — maximum side clearance of equipment boundary below H1 from bilateral datum plane.

9.8 *W2* — minimum side clearance of equipment boundary below H1 from bilateral datum plane.

SEMI G83-0301
SPECIFICATION FOR BAR CODE MARKING OF PRODUCT PACKAGES

This specification was technically approved by the Global Assembly & Packaging Committee and is the direct responsibility of the Japanese Packaging Committee. Current edition approved by the Japanese Regional Standards Committee on December 1, 2000. Initially available at www.semi.org January 2001; to be published March 2001.

1 Purpose

1.1 This specification describes the area needed for adding bar codes, the bar code specifications, and the code notation format for direct and indirect material product packages (unit packs) for semiconductor packaging.

1.2 The following are the goals of this specification:

- Quality control using computers
- Prevention of mistakes created by human error
- Material control at the manufacturing site

1.3 The following is not a goal of this specification:

- Purchasing control

2 Scope

2.1 This specification is to be used for direct and indirect materials relating to packaging materials.

2.2 This specification is to be used for product packages only.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate and safety health practices and determine the applicability of regulatory limitations prior to use.

3 Referenced Standards

3.1 *SEMI Standards*

SEMI G71 — Specification for Barcode Marking of Intermediate Containers for Packaging Materials

3.2 *AIM Specifications*[1]

2 American National Standards Institute, 11 West 42nd Street, New York, NY 10036, tel 212.642.4900, fax 212.398.0023

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

4 Terminology

4.1 Many of the items relating to bar code technology are defined in the AIM Glossary of Terms, ANSI X3.182 (Bar code Print Quality Guidelines).

4.1.1 *data field* — field (area) for adding a bar code to a product package.

4.1.2 *direct material* — components and parts that make up a semiconductor package. Examples include lead frames, molding compounds, bonding wires, die bonding materials, etc.

4.1.3 *HRI (Human Readable Identification)* — characters that can be read by a human.

4.1.4 *indirect material* — supplementary materials and parts used during processing but that do not make up a semiconductor package. Examples include bonding capillaries, dicing blades, etc.

4.1.5 *intermediate container* — container that holds one or more product packages for product/order separation in a shipping container or final container.

4.1.6 *product package* — the smallest package format, made by a single material. Also called a unit pack.

4.1.7 *shipping pack* — package or shipping container/final container (see Figure 1) that is strong enough for industrial use for product packaging, storage, and shipping.

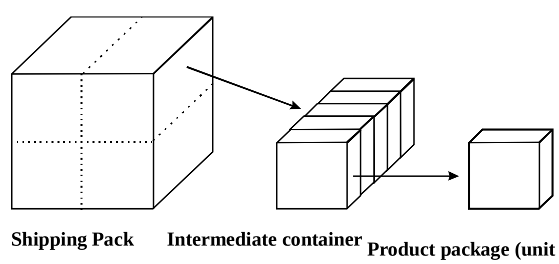

Figure 1
Package Form Regulations

5 Requirements

5.1 *Data Field*

5.1.1 Length is 42 mm or greater, height is 15 mm or greater (see Figure 2 and Table 2).

5.1.2 The noted content bar code is HRI.

5.2 *Bar Code*

5.2.1 *Bar code character* — Bar code characters specified by AIM USS-39 or AIM USS-128 shall be used.

5.2.2 *Printing quality* — according to ANSI X3.182 Bar code Print Quality Guidelines.

5.2.3 *Code dimensions* — the bar code dimensions will be as listed in Table 1.

5.2.4 *Restrictions on use of Code 128* — use only code set B. Also, do not use shift characters within data.

5.2.5 The data digit count will be from 15 to 26 (excluding start/stop characters and check characters).

5.2.6 Use check character.

5.3 *HRI (Human Readable Identification)*

5.3.1 Just below the bar code located in the data field, a field for HRI characters is noted.

5.3.2 The HRI height will be 3.0 mm or greater.

5.3.3 The space between the HRI and bar code shall be 1.0 mm or greater (see Figure 2 and Table 2).

5.4 *Data Contents*

5.4.1 Includes items listed in Table 3.

5.4.2 The sequence, from left to right is as follows: the product recognition number, manufacturing date, sub-lot number, and lot number.

5.4.3 Product recognition number and lot number shall be included.

5.4.4 Manufacture date and sub-lot number shall be written in fixed digits. Remaining unused digits shall be filled by minus codes "-".

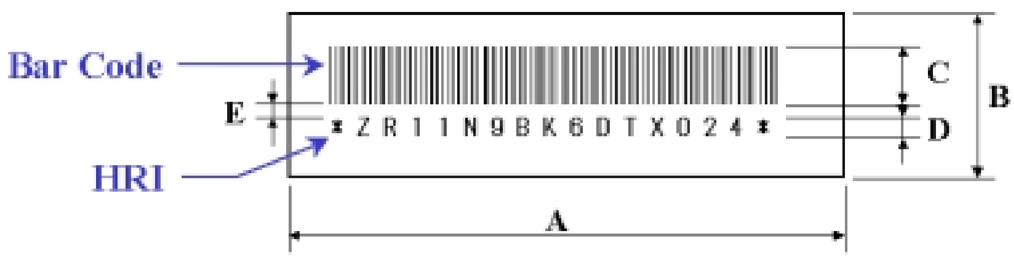

Figure 2
Data Field Dimensions and Placement

Table 1 Code Dimensions

Code 39, Code 128	Dimensions
Minimum element width	0.15 mm or greater.
Code 39 wide bar width	Greater than 2 times, but less than 3 times the minimum element width.
Gap between characters	Minimum element width or greater.
Character height	8.0 mm or greater.
Quiet zone	10 times or greater than the minimum element size (before and after the bar code).

Table 2 Data Field Dimensions

Item	*Dimensions*
Data field length	A ≥ 42 mm
Data field height	B ≥ 15 mm
Bar code height	C ≥ 8 mm
HRI character height	D ≥ 3 mm
Space between bar code and HRI	E ≥□ 1 mm

Table 3 Data Contents (see Appendix 1)

Field Name	*Product Recognition No.*	*Manufacturing Date*	*Sub-Lot No.*	*Lot No.*
Meaning	Code used by user mainly to characterize products.	Date the material was manufactured	Code for characterizing the product package	Code used by supplier mainly to characterize products
Number of digits	5 to 12	3	2	5 to 9
Note	No regulations.	1st digit: Last digit of Gregorian calendar year. 2nd digit: Month indication, note that A = October, B = November, C = December. 3rd digit: Day indication, note that A = the tenth, B = the eleventh, C = the twelfth, ... U = the thirtieth, V = the thirty-first.	No regulations.	No regulations.

APPENDIX 1

NOTE: The material in this appendix is an official part of SEMI G83 and was approved by full letter ballot procedures on December 1, 2000 by the Japanese Regional Standards Committee.

This information explains AIM Specifications listed in Section 3.1 and examples of Data Contents specified in Table 3.

SEMI G84-1101
SPECIFICATION FOR STRIP MAP PROTOCOL

This specification was technically approved by the Global Automated Test Equipment Committee and is the direct responsibility of the North American Automated Test Equipment Committee. Current edition approved by the North American Regional Standards Committee on August 27, 2001. Initially available at www.semi.org September 2001; to be published November 2001.

1 Purpose

1.1 The purpose of this specification is to provide definition that will enable the implementation of strip mapping throughout the assembly and test process. This document will enable standardization of the strip map format and execution method throughout the factory floor.

1.2 This document describes the format and methods in which strip map information shall be formatted and used to transfer information about a strip to and from equipment using the SECS/GEM interface standard (see SEMI E5).

2 Scope

2.1 This specification will identify the messages within the SECS/GEM message set used in the implementation of strip mapping.

2.2 This specification will identify the Map Data Items (MDI) that are required or optionally may be used in the implementation of strip mapping.

2.3 This document will provide basic application notes to aid in the proper implementation of strip mapping.

2.4 This document will not address application or implementation for wafer test process.

2.5 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This document does not address the transmission, file naming conventions, storage or archiving of strip maps.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI E5 — SEMI Equipment Communications Standard Message Content (SECS II)

SEMI G81 — Specification for Map Data Items

SEMI T9 — Specification for Marking of Metal Lead-Frame Strips with a Two-Dimensional Data Matrix Symbol.

NOTE 1: Unless otherwise indicated, all documents cited shall be the latest published versions.

5 Terminology

5.1 *assembly site* — the sub-contractor, supplier's facility or department that will be responsible for the assembly of IC devices.

5.2 *bottom-side* — the bottom of the strip as defined by the customer based on the customer master manufacturing drawing.

5.3 *cell* — a term used to represent the mapping item on a strip – unit, package, device, multi-chip module, etc.

5.4 *strip* — a leadframe, board, panel or other container which hold locations for semiconductor devices to be manufactured upon.

5.5 *strip map* — a record of data in a file that contains quality and historical information about each individual strip in a manufacturers lot.

5.6 *supplier* — a supplier of inspected / tested substrates (strips) and strip maps to the assembly site.

5.7 *substrate* — a board or panel containing locations for semiconductor devices to be manufactured upon. Also referred to as strip, board or PCB.

5.8 *top-side* — the top of the strip as defined by the customer based on the customer master manufacturing drawing.

6 Ordering Information

None.

7 Convention

7.1 The following conventions are used to represent data format. Each format is represented by an alphabetic character and optional data size given by "byte" unit. Exceptions are "*" and "List of". Refer to SEMI E5 for details.

7.1.1 A — ASCII character(s), may not be required terminal character such as null (00_{16})

7.1.2 B — Binary

7.1.3 I — Integer number

7.1.4 U — Unsigned Integer number

7.1.5 List of — Combined item format consisting of one or more items; array (items of the same type) or structure (items of different types)

7.1.6 * — Any format as above or those allowed in SEMI E5.

8 Object Definitions

8.1 The implementation of Strip Mapping defines one standard object, the Strip Map.

8.1.1 *Strip Map Object Definition* — The Strip Map is a dynamic object created and modified through the assembly and test process. Each Strip Map Object is a logical representation of a manufacturing lead frame or substrate and maintains the current processing state for the group of die attached to that physical leadframe or substrate. Each Strip Map Object uniquely identifies a manufacturing leadframe or substrate using the ObjID (StripID) object attribute. The object attribute notation used in Table 1 is described in Conventions, Section 7.

9 Requirements

9.1 *Equipment Communication*

9.1.1 Communication of strip maps between host and equipment shall use the SECS I or HSMS protocols. Otherwise, some other general protocols, which are widespread in the data communication field, could be used as an alternative. However, these are not covered in this specification.

9.2 *Map Data Items*

9.2.1 The Standard Map Data Items in Table 1 contain the standard data items that shall be used in all strip mapping implementations.

9.2.2 The Strip Map Data Items in Table 2 are the data items and object attributes that will be used in the implementation of strip mapping via the SECS/GEM interface as needed by each equipment type and process step.

Table 1 Standard Data Item/Object Description and Settings

Data Item	*Description / Settings*	*Format*
SMORLOC	0 = Error 1 = Upper right 2 = Upper left 3 = Lower left 4 = Lower right > 4 = Error 5-63 Reserved	U1
ERRCODE1	Expected error codes 0 = Unknown strip map ID 1 = Column Count conflict with existing strip map 2 = Row Count conflict with existing strip map 3 = Conflict in Map size and Row/Column count	U2
ERRTEXT	Error text, according to Errcode “Unknown strip map ID” “Column Count conflict with existing strip map” “Row Count conflict with existing strip map “ “Conflict in Map size and Row/Column count”	A
OBJACK	Strip map acknowledge 0 = successful 1 = failed	B
ATTRID	Object attribute ID	A
ATTRDATA	Object attribute data	*
ACKC6	Strip map acknowledge 0 = successful 1 = failed	B
OBJSPEC	A text string that has an internal format and that is used to point to a specific object instance.	A

Data Item	Description / Settings	Format
	The string is formed out of a sequence of formatted substrings, each specifying an object's type and identifier. The substring format has the following four fields: object type, colon character ":", object identifier, greater than symbol ">", where the ":" is used to terminate an object type and the ">" is used to terminate an identifier field. The object type may be omitted where it may be otherwise determined. The final ">" is optional. The OBJSPEC for the StripMap Object is a zero-length item. No specifier required.	
OBJTYPE	Identifier for a group or class of objects. All objects of this type must have the same set of attributes. Available object types: "StripMap"	A
OBJID	Object Identifier	A

Table 2 Strip Map Data Item/Object Description and Settings

Attribute Name	*Definition*	*Access*	*Required*	*Format*
ObjType	The object type, "StripMap"	RO	Y	A = "StripMap"
ObjID	The object. This is the StripID, FrameID or equivalent.	RO	Y	A
CellStatus	Cell Status is an array of values indicating the value of each unit/package/device on a strip. 0 = Functional Good Cell; Good die placed on Good cell. 1 = Unknown Cell Status. 2 = Defect/Non-functional Cell; the cell is marked as defect by previous steps. CellStatus shall be sent in an array of size Rows × Columns in row major format with respect to the OriginLocation. CellStatus may be provided by the host to the equipment as well as from the equipment to the host. Used in: Strip Map Upload and Strip Map Download	RW	Y' Either CellStatus or CellGrade or both are required if mapping is to be used.	List of U1
CellGrade	CellGrade is an array of values indicating the classification of each unit/package/device/cell on a strip. The process and equipment using a 'grading' scheme determine this classification and the associated values. Examples of a CellGrade are test bins, sort grades, package grade, marking grades etc. CellGrade shall be sent in an array of size Rows × Columns in row major format with respect to the OriginLocation.	RW	Y' Either CellStatus or CellGrade or both are required if mapping is to be used.	List of U1
Columns	The number of columns of (measured) device matrix on substrate, that is the number of devices on the X-axis of the map data. It is required if the type of the map data is simple array structure.	RO	Y	U4

Attribute Name	*Definition*	*Access*	*Required*	*Format*
OriginLocation	Coordinate system on substrate to address devices. Location of the datum point or the origin of the coordinates shall be one of the following: 0 = Not currently supported 1 = Upper right – top side 2 = Upper left – top side 3 = Lower left – top side* 4 = Lower right – top side 5 = Not currently supported 6 = Upper right – bottom side 7 = Upper left – bottom side 8 = Lower left – bottom side 9 = Lower right – bottom side * Default value is 3 (=Lower left – top side) if this item is not present. Typically Used in: Strip Map Upload and Strip Map Download	RO	Y	U1
Rows	The number of rows of (measured) device matrix on substrate, that is the number of devices on the Y-axis of the map data. It is required if the type of the map data is simple array structure.	RO	Y	U4
SubstrateID	A character code that may be printed or encoded on the substrate, which uniquely identifies the substrate, and can be used to correlate the map with physical substrate. SubstrateID is either StripID or FrameID.	RW	Y	A
BinGrade	A BinCode (see SEMI G81) is a value describing the grading of a die. BinGrade is an array of bin codes used to describe each die on the wafer. BinCodeList shall be sent in an array size Rows x Columns in row major format with respect to the OriginLocation. Typically used in: Strip Map Upload	RW	N	U1
DefectCode	DefectCodes are a set of codes representing defects that are detected at each process step by equipment or a human. DefectCodes shall be sent in an array of size Rows × Columns in row major format with respect to the OriginLocation. If there is no defect, the DefectCode is 0 (Zero) Typically Used in: Strip Map Upload and Strip Map Download	RW	N	List of U1
LotID	Production lot identifier for this data.	RW	N	A

Attribute Name	Definition	Access	Required	Format
ContainerID	A character code that may be printed or encoded on the substrate carrier, which uniquely identifies the substrate carrier. ContainerID can be MagazineID, CarrierID or CassetteID.	RW	N	A
WaferID	A character code that may be printed or encoded on the wafer, which uniquely identifies the wafer. Used when equipment reports wafer id with or in parallel with strip map data.	RW	N	A
XYPosition	XYPosition represents the X and Y coordinate position of the die on the wafer. XYPosition must be in (X,Y) order multi-item and shall be made up of data items DieX and DieY (See SEMI G81). For each XYPosition a WaferID is given. This information is used when wafer id and die location on the wafer is to be associated with the strip id and location of the unit/package/device/cell on a strip. XYPosition is set to 32767, 32767 when a strip is removed from the equipment. This represents no wafer die information. Valid range for X and Y is 1..32767	RW	N	List of I2

9.3 *Map Data Protocol*

9.3.1 The strip mapping standard implementation shall use the SECS/GEM standard Object Services (F14,F1/F2) and standard Collection Event S6,F11/F12 Streams and Functions for the transfer of Strip Maps to and from equipment (see SEMI E5).

9.3.2 The use of object services will allow the equipment to request the type of information from the host with predefined attributes. The host will then reply with the list of attributes requested. This will enable application specific behavior of the mapping process by equipment types.

9.3.3 The use of the Collection Event Streams and Functions will allow event-based communication from the equipment to the host on the status of the strip mapping process.

9.3.4 *Strip Map Download*

9.3.4.1 The equipment shall request a strip map download from the host using the Standard Object Services (OSS) command, S14,F1 GetAttribute Request (GAR). Please refer to Section 9.2.1.

9.3.4.2 The equipment shall include all mandatory data attributes in GAR request as well as any optional information required by the particular equipment to implement the strip mapping capability.

9.3.4.3 The host will respond to the GetAttribute Request with an S14,F2, Get Attribute Data (GAD).

9.3.5 *Strip Map Upload*

9.3.5.1 The equipment will provide updates to the strip map via the S6,F11 event.

9.3.5.2 All mandatory data items are required to be included in the upload event along with any optional equipment specific data items. Please refer to Section 9.2.2 for examples.

10 Description

10.1 See SEMI G81 for further definitions of the strip map required items.

10.2 *Strip Map Required Attributes*

10.2.1 The following set of Data Items are mandatory in the uploads and downloads scenarios for strip maps.

- Strip ID
- Rows
- Columns
- OriginLocation
- CellStatus | CellGrade

10.2.2 Each equipment shall have an attribute for the product or strip type that will describe the standards process direction and physical origin of the strip. If the physical origin and the factory defined origin are not the same, it is the responsibility of the equipment to perform the appropriate translations to maintain integrity of the strip map information.

10.3 *Strip Map Data Protocol Examples*

10.3.1 *Strip Map Download (Example)*

S14,F1 GetAttr Request (GAR) S,H<-E

10.3.1.1 Description: This message is used to request a set of specified attributes for one or more objects.

Structure: L,5

1. <OBJSPEC = ‘’>
2. <OBJTYPE = ‘StripMap’>
3. L,1
   1. <OBJID1 = StripID = ‘A1000001’>
4. L,0 (always zero list, no filters defined)
5. L,5 (any length and order of data items)
   1. <ATTRID = OriginLocation >
   2. <ATTRID = ‘Rows ' >
   3. <ATTRID = ‘Columns ' >
   4. <ATTRID = ‘CellStatus' >
   5. <ATTRID = ‘LotID' >

NOTE: This is an example only. Each equipment must request all mandatory data items and can additionally request any optional data items that it needs to fully implement strip mapping capability.

S14,F2 GetAttr Data (GAD) M,H->E

10.3.1.2 Description: This message is used to transfer the set of requested attributes for the specified object(s). The order of attributes is retained from the primary message.

Structure: L,2

1. L, 1
   1. L,2
      1. <OBJID = StripID = ‘A1000001’>
      2. L,5
         1. L,2
            1. <ATTRID = ‘OriginLocation’ >
            2. <ATTRDATA = ‘0’>
         2. L,2
            1. <ATTRID = ' Rows’>
            2. <ATTRDATA = 6>

3. L,2
1. <ATTRID = '   Columns ' >
2. <ATTRDATA = 24>
4. L,2
1. <ATTRID = '   CellStatus' >
2. <ATTRDATA = 6>
5. L,2
1. <ATTRID = '   LotID ' >
2. <ATTRDATA = ' Lot1>
2. L,2
1. <OBJACK = 0>
2. L,0

10.3.2 *Strip Map Upload (Example)*

S6,F11   Event Report   M, H<-E

10.3.2.1 Description: This message is used to report the current map status. This event will occur at the end of a strip as well as at any point during the processing of the strip when the equipment enters a condition where an operator may have the opportunity to handle the strip or the equipment has an opportunity for error. This event shall always be sent with the current status of the map at the time the equipment gets changed from local to remote.

10.3.2.1.1 For a description of filters, see S6,F11.

Structure: L,3
1. <DATAID>
2. <CEID>
3. L,1
1. L,2
1. <RPTID>
2. <L,n
1. <xxxx>
n. <yyyy>

S6,F12   Event Report Acknowledge   H->E

Description: Acknowledge or Error

Structure: <ACKC6>

11 Application Scenarios

11.1 *Strip Map Download*

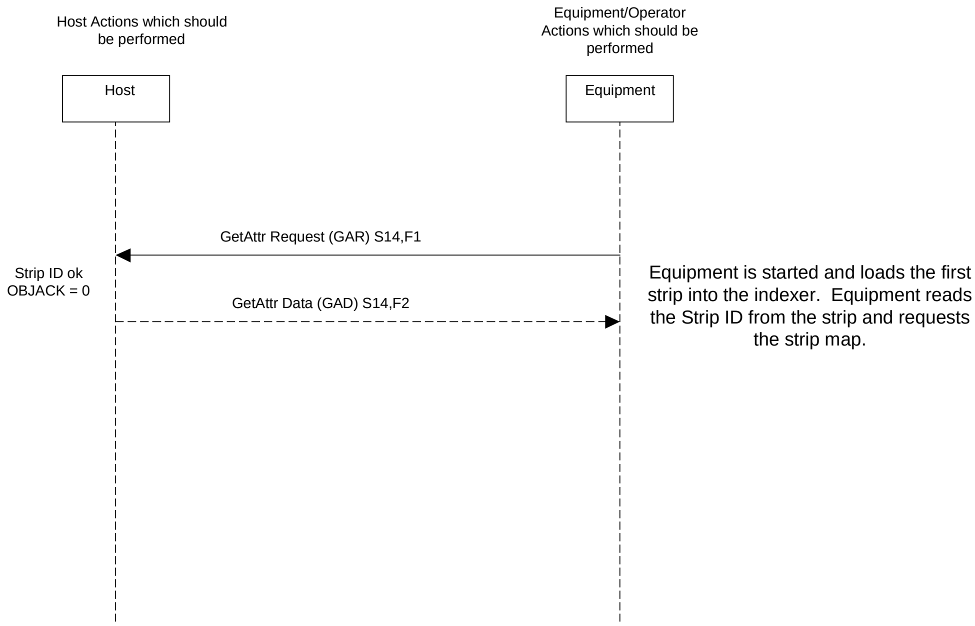

Figure 1
Strip Map Download

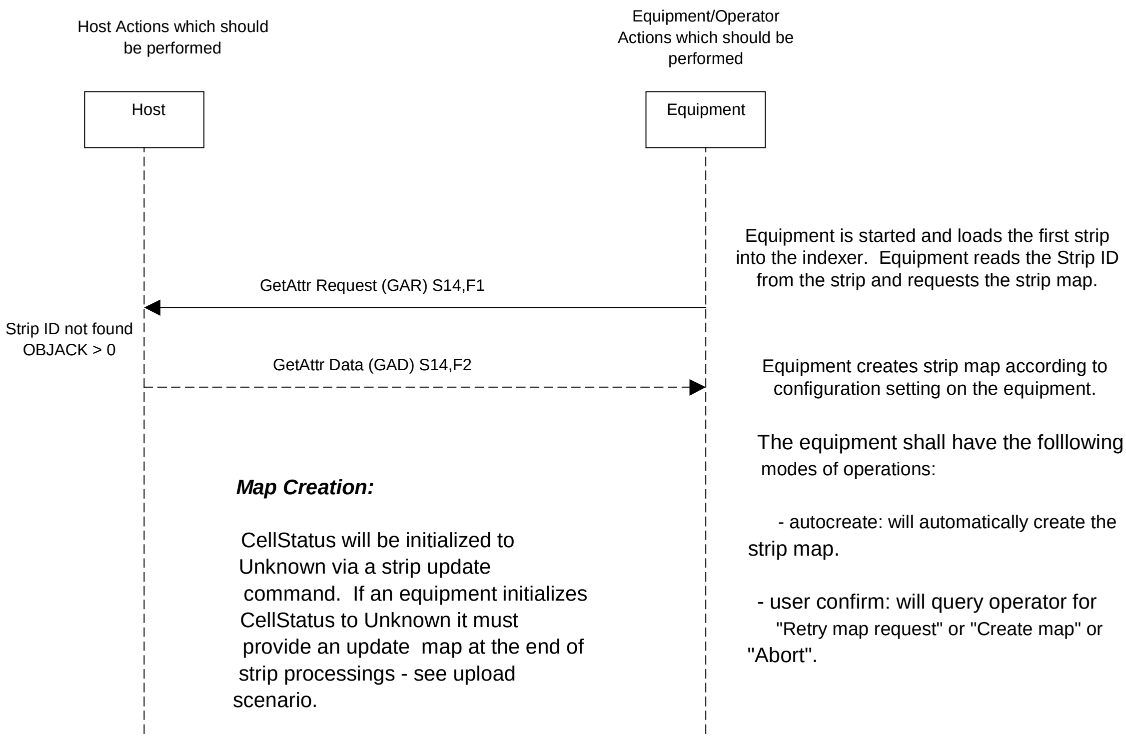

Figure 2
Strip Map Create

11.1.1 A typical equipment scenario is that for each strip arriving at the equipment input, a strip map request (S14,F1) and subsequent download (S14,F2) will occur. See Figure 1. Depending on the equipment type, there may be some variations on the optional attributes requested, the timing of events and exception handling.

11.2 *Strip Map Creation*

11.2.1 A map must exist before it can be sent to an equipment type. Some equipment may be required to support the creating of the map for the first time. See Figure 2. For these equipment two modes are identified, “autocreate” and “user confirm”. To use these modes the equipment shall behave as indicated below.

11.2.2 If equipment supports an “autocreate” mode the equipment will process the strip as normal when a new strip arrives. The equipment will assume each location on the strip has an unknown status. Should the equipment be required to send a strip map during processing due to equipment errors, the strip map shall contain the unknown CellStatus value whenever the status is unknown. All other CellStatus indicators shall be “Good” or “Bad”. See Upload scenario.

11.2.3 If equipment supports a “user confirm” mode, the equipment shall request operator intervention to decide how to deal with a missing strip map. The options are “Create map” or “Abort”. If the operator selects “Create map” the above scenario will be valid. If the operator selects “Abort”, the equipment shall send an alarm to the host and not process the strip. The strip will not be processed unless the equipment is removed from the “strip map” mode.

11.3 *Strip Map Upload*

11.3.1 For equipment with the capability of detecting defective units on a strip, a strip map upload is required. The upload will report new definitions of each “cell”.

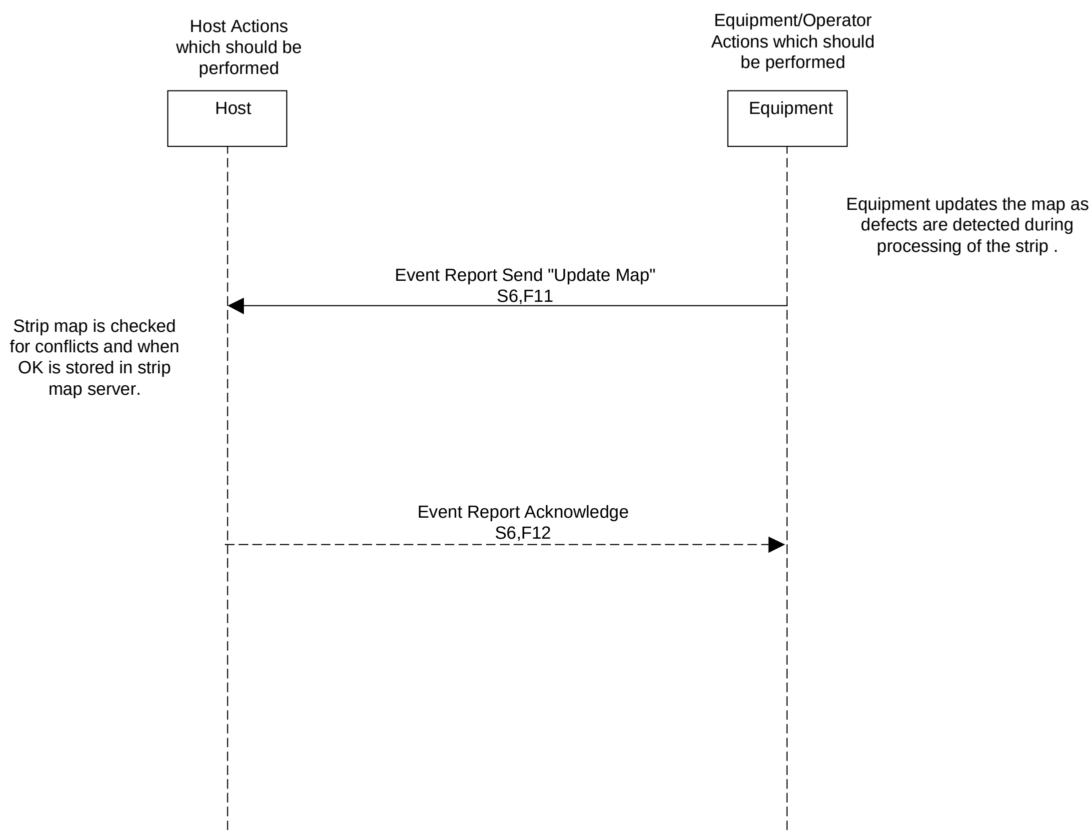

Figure 3
“Update Map” Event

11.3.1.1 An Event Report “Update Map” will be sent if new defects have been detected and not previously logged to the host for the following conditions. See Figure 3.

1. At the end of processing current strip if new defects have been detected
2. Whenever the equipment changes state from Remote to Local
3. Whenever the equipment interlocks are triggered
4. Whenever the equipment stops and requires operator intervention.

11.3.2 *Unsuccessful Transaction*

11.3.2.1 Equipment will stop and signal an alarm to the host if the equipment detects that a strip map has not been successfully uploaded to the host.

11.3.2.2 When possible, the equipment shall support intervention by the Operator with the following corrective actions:

1. “retry upload”
2. “abort upload”

11.3.2.3 If the “retry upload” is selected the Upload Event will be resent to the host.

11.3.2.4 If “abort” is selected by the operator an appropriate Event shall be sent with the strip map ID to indicate to the host that the strip map has been aborted. The equipment will not process the strip unless the equipment is removed from “strip map” mode.

11.4 *Strip End Event*

11.4.1 At the end of each strip, a strip end event shall be sent to the host which indicates that the strip has successfully completed the activity at that equipment.

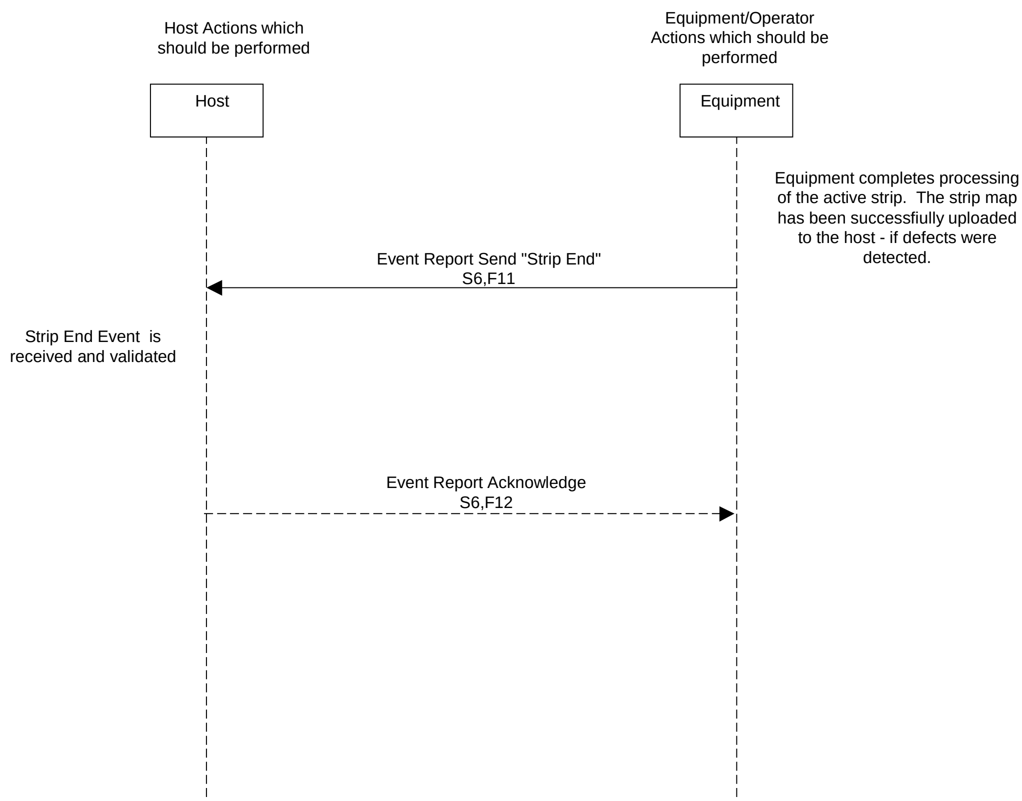

Figure 4
“Strip End” Event

11.5 *In Process Strip Map Related Errors*

11.5.1 Each equipment type shall define the type of errors that can occur during processing which could cause strip map integrity problems and provide documented scenarios of how the equipment will handle each situation.

11.5.2 Some potential erroneous situations:

- Equipment lost strip map while processing
- Strip is removed prior to completing processing strip
- Strip jams before being moved out of equipment – no Strip Map End Event occurred

APPENDIX 1
STRIP MAP

NOTE: The material in this appendix is an official part of SEMI G84 and was approved by full letter ballot procedures on August 27, 2001.

A1-1 This appendix shows how the map data items may be applied to strips as well as some additional information specific to this substrate type.

A1-2 The StripID shall follow the SEMI T9 specification, when applicable, or may be user definable by the factory.

A1-3 For any given process there must be a way to ensure correct orientation of the strip. The end user is responsible for providing a master manufacturing drawing showing the top side of the strip. This drawing must show any special markings or patterns that are needed to reliably flip and rotate a physical strip until it is oriented the same as the drawing. Figure A1-1 defines what is meant by top side and hence bottom side. It also defines what is meant by upper, lower and left and right.

A1-4 Each strip type will have a factory defined value for OriginLocation. This is the origin reference for the row 1, column 1 location on the strip. The factory origin, OriginLocation is selected as one of four corners by the factory host system. The row and column index will be referenced from the selected reference. This information will be provided to the equipment by the host in each strip map download scenario.

1 = Upper right (UR) top side

2 = Upper left (UL) top side

3 = Lower left (LL) top side

4 = Lower right (LR) top side

6 = Upper right (UR) bottom side

7 = Upper left (UL) bottom side

8 = Lower left (LL) bottom side

9 = Lower right (LR) bottom side

SEMI G85-1101
SPECIFICATION FOR MAP DATA FORMAT

This specification was technically approved by the Global Automated Test Equipment Committee and is the direct responsibility of the North American Automated Test Equipment Committee. Current edition approved by the North American Regional Standards Committee on August 27, 2001. Initially available at www.semi.org September 2001; to be published November 2001.

1 Purpose

1.1 This document describes in detail how the data items that relate to electronic mapping are to be represented in a file format.

1.2 Although the examples given in this document are for wafers, the map data format described can be applied to any substrate including, but not limited to; wafer, tray, strip or tape.

2 Scope

2.1 This document applies to format of map data items. This document does not address the transmission, file naming conventions, storage or archiving of maps.

2.2 The semantics of the map data items are not specified in this document.

2.3 The specification of which data items are optional and which are required is not specified in this document.

2.4 The size of each data item is not specified in this document.

2.5 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This document is limited to representing maps for MapType =”Array”. See SEMI G81 for a definition of MapType.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI G81 — Specification for Map Data Items

4.2 *World Wide Web Consortium Documents*[1]

Extensible Markup Language (XML) 1.0 (Second Edition. Namespaces in XML)

NOTE 1: Unless otherwise indicated, all documents cited shall be the latest published versions.

5 Terminology

5.1 *map* — a two dimensional array of bin codes derived from electrical test data of a two dimensional substrate including, but not limited to; wafer, tray, strip or tape.

6 Ordering Information

None.

7 Description

7.1 XML Notation Extensible Markup Language is the universal language for data on the Web. It gives developers the power to deliver structured data from a wide variety of applications to the desktop for local computation and presentation. XML allows the creation of unique data formats for specific applications. It is also an ideal format for server-to-server transfer of structured data.

7.2 XML consists of nodes (referred to as ‘items’ in the remainder of this document) that may have attributes and nested items.

7.2.1 Example:

```
<Map xmlns:semi="http://www.semi.org" >
  <Device>
  </Device>
</Map>
```

defines a Map item with the attribute xmlns:semi="http://www.semi.org" which defines a namespace and the governing body for that namespace. This is in accordance with the “Namespaces in XML” specification (see references). Specifying the

1 World Wide Web Consortium Documents are available from Massachusetts Institute of Technology Laboratory for Computer Science, 200 Technology Square, Cambridge, MA 02139, USA Telephone: + 1.617.253.2613, Fax: + 1.617.258.5999, http://www.w3.org/TR/REC-xml

namespace ensures that the names within the Map node are distinguishable from the same names in other non-SEMI XML documents.

7.2.2 The Map item contains a nested item called Device.

7.3 The listing below is an example[2] of a well-formed map data file for a single map with all the map data items except for Label and SupplierValue. The elements of this template will be described in the sections that follow. Examples of map data files with data are shown in the appendices.

```
<?xml version="1.0"?>
<Map
 xmlns:semi="http://www.semi.org"
 WaferId=" "
 FormatRevision=" ">
 <Device
  ProductId=""
  LotId=" "
  Orientation=""
  DeviceSizeX=""
  DeviceSizeY=""
  Rows=""
  Columns=""
  BinType=" "
  FrameId=" "
  NullBin=""
  SupplierName=""
  OriginLocation=""
  CreateDate=""
  Status="">
  <ReferenceDevice
   ReferenceDeviceX=""
   ReferenceDeviceY=""
   RefDevicePosX=”"
   RefDevicePosY=""
  />
  <Bin
   BinCode=""
   BinQuality=""
   BinDescription=""
  />
  <SupplierData
   MyData=" "
  />
  <Data MapName=" " MapVersion="">
    <Row><! [CDATA[]]></Row>
  </Data>
 </Device>
</Map>
```

2 This example is for a wafer map identified by WaferId. Other substrate types may also be represented. See Table 1.

7.3.1 The order of attributes and sub items within their parent item is not significant but the parent child relationship is. One exception is the Row items which must match the actual rows on the substrate being mapped.

7.4 Every map file starts with the declaration:

```
<?xml version="1.0"?>
```

This line informs the parser that the data that follows conforms to the XML Version 1.0 specification.

7.5 The data for each wafer is enclosed within the map data item…

```
<Map xmlns:semi="http://www.semi.org"
WaferId=”ZSDGS88DF”>
</Map>
```

7.5.1 The attribute setting, xmlns:semi=“http://www. semi.org” informs the parser that the item and attribute names within this item are unique within the namespace identified as SEMI.

7.5.2 All the attributes within the Map item are defined in the SEMI G81.

7.5.3 All the items within the Map Item are defined in this document except for the sub items of the SupplierData item.

7.5.4 Some of these attributes and items are mandatory and some are optional as defined in Table 1.

7.5.5 One or more maps can be represented in a single file by simply repeating the <Map> tag. Each map can be distinguished based on an identifier attribute as shown in the following example:

```
<Map xmlns:semi="http://www.semi.org"
WaferId="ZSDGS88DF" >
</Map>
<Map xmlns:semi="http://www.semi.org"
WaferId="JDUJ102MJS" >
</Map>
```

7.6 The Map item contains one or more Device items. This allows multiple overlaying maps of different device types to be represented. The Device item contains a number of attributes and some sub items.

7.6.1 The ReferenceDevice item contains attributes which describes a single reference device. Several ReferenceDevice items may be represented by repeating this item with different attribute values.

7.6.2 The Bin item contains attributes which describes a single bin code. Several Bin items may be represented by repeating this item with different attribute values.

7.6.3 The SupplierData item contains attributes which are defined by the supplier of the map.

7.6.4 The Data item contains attributes and a list of Row items. Several Data items may be represented by repeating this item with different attribute values. This might be used for example to represent versions of the map after each process step.

7.6.5 The Row items are defined as XML CDATA section. The example below shows the Data item for a binary map with two rows and two columns.

```
<Data>
    <Row><! [CDATA[FFFF]]></Row>
    <Row><! [CDATA[FF14]]></Row>
</Data>
```

7.6.5.1 A CDATA section contains data that should not be parsed by the XML parser. After <! [CDATA[, only the string]]> will be interpreted by the XML parser. If this string occurs in the actual data (for example in an ascii map) then it must be replaced by the string]]> so that the XML parser will not interpret it as the end of the CDATA section.

7.6.5.2 Each Row item specifies the BinCode for each column in the row in a format that depends on the BinType attribute.

7.6.5.3 The Row items must match the actual rows on the substrate being mapped. The first row is the topmost row as viewed with the substrate oriented according to the value of Orientation.

7.6.5.4 The number of Row items must match the Rows attribute if specified.

7.6.5.5 The number of columns in each Row item must match the Columns attribute if specified.

Table 1 Items and Attributes Used

Name	*Item or Attribute*	*Defined In*	*Mandatory or Optional*	*Default Value*
xmlns	Attribute	Map Data Format	Mandatory	Must be “http://www.semi.org”
WaferId	Attribute	Map Data Items	Mandatory	No default
StripId	Attribute	Map Data Items	Mandatory	No default
TrayId	Attribute	Map Data Items	Mandatory	No default
NullBin	Attribute	Map Data Items	Mandatory	No default

APPENDIX 1
EXAMPLE MAP DATA FILES[4]

NOTE: The material in this appendix is an official part of SEMI G85 and was approved by full letter ballot procedures on August 27, 2001.

A1-1 Simple Ascii Wafer Map

A1.1 This example illustrates the simplest possible wafer map. It uses ascii bin codes and contains only the required data items.

```
<?xml version="1.0"?>
<Map xmlns:semi="http://www.semi.org"
WaferId="ZSDGS88DF" >
  <Device
    NullBin=" "
    <Data >
      <Row><! [CDATA[  2C  ]]></Row>
      <Row><! [CDATA[ ~2C2 ]]></Row>
      <Row><! [CDATA[222A1~]]></Row>
      <Row><! [CDATA[21~C22]]></Row>
      <Row><! [CDATA[ ~2C2 ]]></Row>
      <Row><! [CDATA[  2C  ]]></Row>
    </Data>
  </Device>
</Map>
```

A1-2 Detailed Binary Wafer Map

A1-2.1 The example below illustrates the use of binary bin codes and contains not only the required data items, but also some data items provided by the supplier.

```
<?xml version="1.0"?>
<Map xmlns:semi="http://www.semi.org"
WaferId="ZSDGS88DF" FormatRevision="SEMI
Draft Document #3157A">
  <Device
    ProductId="854CS1C"
    LotId="wksfd87dcj37"
    Orientation="0"
    DeviceSizeX="343.8"
    DeviceSizeY="373.1"
    Rows="6"
    Columns="6"
    BinType="HexaDecimal"
    FrameId="KJKSDFK45"
    NullBin="FF"
    SupplierName="Company X"
    OriginLocation="1"
    CreateDate=""
    Status="Product">
    <ReferenceDevice
      ReferenceDeviceX="2"
      ReferenceDeviceY="-3"
      RefDevicePosX="2"
      RefDevicePosY="2"
    />
    <ReferenceDevice
      ReferenceDeviceX="4"
      ReferenceDeviceY="-5"
      RefDevicePosX="2"
      RefDevicePosY="2"
    />
    <Bin
      BinCode="02"
      BinQuality="Pass"
      BinDescription="500MHz"
    />
    <SupplierData
      Origin="USA"
      Destination="Asia"
```

4 These examples are for a wafer map identified by WaferId. Other substrate types may also be represented. See Table 1.

```
  />
  <Data MapName="SortGrade" Version="1">
   <Row><! [CDATA[FFFF020CFFFF]]></Row>

SEMI INTERNATIONAL STANDARDS

PROCESS CHEMICALS

Semiconductor Equipment and Materials International

SEMI C1-1101
SPECIFICATIONS FOR REAGENTS

This specification was technically approved by the Global Process Chemicals Committee and is the direct responsibility of the North American Process Chemicals Committee. Current edition approved by the North American Regional Standards Committee on August 27, 2001. Initially available at www.semi.org September 2001; to be published November 2001. Originally published in 1980; previously published in July 2001.

1 Preface

1.1 In the 1950's, chemicals purchased by the electronics industry were of a quality defined by the Committee on Analytical Reagents of the American Chemical Society, or of lesser quality. With recognition of the importance of impurity content of chemicals in the manufacture of semiconductors, suppliers responded by introducing products with improved analytical characterization, notably for trace elements.

1.2 The SEMI Committee on Standards for Chemical Reagents began its efforts in the fall of 1975. With this publication, the Committee establishes the definitions, general procedures, specifications, and analytical procedures for the chemicals listed in the index.

1.3 Products within all of the requirements can be described as "meeting SEMI specifications."

1.4 Where an analytical procedure different from that provided is substituted by a supplier or user, the burden of proof is on said supplier or user to confirm the equivalency.

1.5 The committee is continuing work on improvement of specifications and procedures and addition of other reagents and systems such as mixed etchants. The committee welcomes comments, suggestions, and recommendations.

1.6 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

2 Definitions

2.1 *Accuracy and Tolerances in Measurements* — In a test procedure, unless otherwise specified, the accuracy required in the amount of sample taken shall be understood to be within 2.0% of the stated amount, whether a weight or a volume. Where a dilution is performed to a stated volume or a stated volume of a solution is taken, that volume shall be within 2.0% of the stated amount. Unless otherwise stated, a transfer by pipet shall be made by means of a volumetric pipet conforming to the tolerances established by *National Bureau of Standards Circular* 602, April 1, 1959.

2.2 *Abbreviations and Signs* — In this work abbreviations and signs used shall be restricted to those listed in Table 2. Most of the abbreviations are identical to those used in publications of the American Chemical Society as of 1982.

2.3 *Acidity and Alkalinity* — A test for acidity or alkalinity, or both, of organic liquids is common.

2.3.1 In the *acidity test,* usually a stated volume of water (commonly 25 mL) is shaken in a glass-stoppered flask with a stated volume of sample (commonly 10 mL). Then 0.1 mL of phenolphthalein indicator solution is added and 0.01 *N* sodium hydroxide until a slight pink color persists after shaking for 30 seconds. Next, a stated amount of sample is added and mixed, and a titration is performed with 0.01 *N* sodium hydroxide until the pink color is reproduced; the volume of titrant required is recorded.

2.3.2 In the *alkalinity test*, a stated amount of sample is mixed with a stated volume of water (commonly 25 mL). Now 0.05 mL of methyl red indicator solution is added and the mixture is titrated with 0.01 *N* hydrochloric acid until a slight pink color is reached; the volume of titrant required is recorded.

2.3.3 The result of such tests has often been expressed qualitatively as "passes test" or quantitatively as the content of an acid (or base) known or assumed to be present. In this work, the maximum specification limit shall be expressed in microequivalents of acid (or base) per gram of sample (μeq/g). The maximum allowed volume of titrant in a test procedure shall correspond to that specification limit.

2.4 *Apparatus* — Apparatus, unless otherwise qualified, shall be that commonly employed in the conduct of the relevant test.

2.5 *Atomic and Formula Weights* — Atomic weights (that is, atomic masses) used shall be those of the latest report of the International Commission on Atomic Weights. Formula weights shall be calculated from a given empirical (molecular) formula by addition of the stated multiples of the atomic weights. Unless otherwise stated, formula weights shall be rounded to 2 significant figures to the right of the decimal point (see Rounding of Numbers, Section 2.18). All relevant factors given in this work are based on the 1975 Table of Atomic Masses.

2.6 *Blank Preparation* — Where a "blank" is specified to be run, unless otherwise stated, it shall be performed with the same quantities of the same reagents and in a manner identical to that followed with the sample portion under test, but with the material itself omitted.

2.7 *Comparison of Analytical Results with Specification Limits* — In the comparison of an analytical result for a test with the numerical limit associated with the specification, the result shall be rounded to the number of significant figures indicated for that limit. (See Rounding of Numbers, Section 2.18.). Consequently, a specification stated at 96% *minimum* will be met by a result as small as 95.5%, and that stated as 96.0% *minimum* will be met by a result as small as 95.95%. A specification of 0.1% *maximum* will be met by a result as large as 0.14%, and that of 0.10% *maximum* by a result as large as 0.105%. In those specifications given with no digit following the decimal point, such as 10. ppb maximum, a test result as large as 10.5 ppb will meet the specification. This use of a decimal point is made to clarify the difference between converting 0.01 ppm to 10 ppb and converting 0.010 ppm to 10. ppb.[1]

2.8 *Density* — The density of a liquid shall be determined for the compound in air at 25°C and be expressed in grams/milliliter (g/mL). Where the specific gravity, with respect to water, is determined, it shall be expressed as density by the use of tabular values for the density of water at the relevant temperature(s).

2.9 *Desiccator* — A desiccator shall imply a tightly closed container charged with a suitable desiccant (commonly calcium chloride or sulfate) that allows an atmosphere of low humidity to be maintained.

2.10 *Drying or Igniting to Constant Weight* — A statement "dried to a constant weight" or "ignited to a constant weight" shall imply that two separate weighings differ by no more than ± 0.4 mg (unless otherwise specified), where the second weighing follows a second drying (for one hour (unless otherwise stated) or ignition for 15 minutes (unless otherwise stated), respectively.

2.11 *Expression of Content and Concentration* — Unless otherwise stated, a specification limit and experimental results related to it shall be expressed in units of weight by weight. The concentration of a solution of a test reagent shall be expressed either in molarity or normality or as percent weight by volume. A redox normality value shall always be followed, parenthetically, by the relevant molarity. ln the approximate dilution of reagents, a parenthetical expression of two numbers with an intervening "plus" sign shall imply that the relative volume of the stated reagent given by the first number shall be admixed with the relative volume of water given by the second number. Thus, "dilute" sulfuric acid (1 + 3) directs that one volume of reagent grade sulfuric acid be added to 3 volumes of water and the mixture stirred to form a uniform solution.

2.12 *Filtration* — A statement to "filter," unless qualified, shall imply filtration through suitable filter paper until the filtrate is clear.

2.13 *Heavy Metals (as Pb)* — The test described as "Heavy Metals (as Pb)" responds to many of the metals precipitated by hydrogen sulfide. Unless otherwise stated, the test shall involve a visual comparison of the color developed by the sample preparation and a lead standard ("control"), upon treatment with hydrogen sulfide at pH 3 to 4. The color comparison shall be made with matched 50 mL Nessler tubes with vertical viewing over a white background. The treatment of the sample shall be specified in detail in the test procedure. Unless otherwise stated, the heavy metals standard shall be prepared by diluting a solution containing 0.02 mg of lead with water to 25 mL, adjusting the acidity of this solution to pH 3 to 4 (using a pH meter), and then diluting with water to 40 mL, and mixing. The test shall then be conducted by adding to that standard and to 40 mL of the stated sample solution 10 mL of freshly prepared hydrogen sulfide water with mixing. The test shall have been passed if the sample solution is no darker than the standard. This test is proximate in nature and does not imply that lead is present either alone or with other heavy metals.

2.13.1 For sodium hydroxide and potassium hydroxide, this test becomes "Heavy Metals (as Ag)," and silver replaces lead in the standard. This change is appropriate as silver and silver-clad equipment are often used in the manufacture of these caustics.

2.14 *Physical Properties* — Physical properties shall not usually be employed for specification purposes; for information, however, representative values for a particular chemical, as supplied, may be included as item 2 in the monograph for that chemical. Where relevant, physical properties shall be specified for 25°C.

2.15 *Reagent Chemicals* — Unless otherwise stated, reagents to be used in tests shall conform to the minimum standards of quality set forth in the 8th Edition of *Reagent Chemicals*, published by the American Chemical Society, and any revisions thereto.

2.16 *Residue after Evaporation* — A "residue after evaporation" test is often used in the assessment of organic liquids. (See Determination of Residue after Evaporation, Section 3.3.)

1 H.A. Flachka, A.J. Barnard Jr., P.E. Sturrock. Quantitative Analytical Chemistry, Willard Grant Press, 2nd ed., 1980, p 4.

2.17 *Residue after Ignition* — A "residue after ignition" test serves to assess the amount of nonvolatile inorganic matter present in a sample. Unless otherwise stated, the ignition shall be performed at 800° ± 25°C for 15 minutes. Where the addition of sulfuric acid is specified, the result corresponds to what is often termed "sulfated ash." The calculation of the result, expressed in parts per million (µg/g), takes the form:

$$\text{ppm Residue after Ignition} = \frac{\text{Net weight of residue (g)} \times 10^6}{\text{Weight of sample (g)}}$$

2.18 *Rounding of Numbers* — The following rules for "rounding" of measured or calculated values shall be employed:

1. When the figure next beyond the last place to be retained *is less than 5*, leave unchanged the figure in the last place retained.
2. When the figure next beyond the last place to be retained *is greater than 5*, increase by 1 the figure in the last place retained.
3. When the figure next beyond the last place to be retained is *5 and there are no figures beyond this 5 or only zeroes*, (a) increase by 1 the figure in the last place retained if it is odd, or leave the figure unchanged if it is even.
4. When the figure next beyond the last place to be retained is *5 and there are figures other than zeroes beyond this 5*, increase by 1 the figure in the last place retained.
5. Obtain the rounded value in one step by direct rounding and not in two or more steps of successive roundings.

2.19 *Samples and Sampling* — For chemicals provided in small containers, one (or more) shall be freshly opened for testing, thereby reducing possi-bilities for contamination or change in composition (for example, by moisture pickup). Where the chemical is provided in larger bulk quantities, one or more drums or other containers shall be sampled appropriately, and the combined sample shall be placed in a labeled, well-cleaned container that shall be tightly closed and transferred expeditiously to the testing laboratory.

2.20 *Specifications and Specification Limits* — The specifications provided by this work are intended to serve for chemicals to be used in the manufacture and processing of semiconductors and advanced electronic devices and circuits. The specifications and the associated test procedures are based on the experience of suppliers and users and also on published studies relating to chemicals of the required quality. The function of the specifications is to establish *minimum* standards of quality.

2.20.1 Where feasible, a specification of content shall be expressed as a numerical limit in units of weight by weight. For a specification that cannot be assigned such a limit, the expression "To pass test" shall be used.

2.20.2 For a major component, the value (assay, purity, etc.) shall be expressed as a *minimum* permissible limit. For an impurity, the value shall be expressed as a *maximum* permissible limit.

2.20.3 A chemical conforming to the specification will commonly contain more of the major component than the minimum permissible limit or contain less of an impurity (or several impurities) than the maximum permissible limit. In neither case shall the chemical be considered as of higher quality than that defined by the specification.

2.20.4 It is manifestly impossible in the specifications and procedures for a chemical to consider every impurity or contaminant that might be present. For certain applications, it is recognized that more stringent or additional specifications and procedures might be required. The intent of these specifications and the associated procedures is, on one hand, to assure that a chemical is suitable for the common uses to which it may be put in the manufacture and processing of semiconductor devices and, on the other hand, to be consistent with contemporary manufacturing processes for that chemical.

2.21 *Specification Parameters* — In this work, the order of statement of specification parameters in Item 1 of the monograph for a particular chemical shall be, as far as practical: 1) assay or other test assessing the content of the major component(s); 2) appearance or color; 3) acidity or alkalinity, or both, or pH range of solution; 4) residue after evaporation or ignition; 5) water content; 6) diverse general tests, arranged alphabetically; 7) tests for stated anions, arranged alphabetically (bromide, chloride, phosphate, sulfate, sulfite, etc.); 8) ammonium; 9) heavy metals; 10) arsenic and antimony; 11) tests for specific trace metals, arranged alphabetically by name. The metals for grade specifications higher than Grade 2 are Aluminum, Antimony, Arsenic, Barium, Boron, Cadmium, Calcium, Chromium, Copper, Iron, Lead, Lithium, Magnesium, Manganese, Nickel, Potassium, Sodium, Tin, Titanium, Vanadium, and Zinc.

2.21.1 All major words in a specification parameter shall have their initial letters capitalized.

2.21.2 Following the statement of a specification parameter, where relevant, the species on which the calculation of the result is based shall be expressed parenthetically as the atomic symbol or empirical formula.

2.22 *Tared Containers* — Where the use of a tared container is specified, it shall be carried through operations identical to those used in the test procedures, including drying or ignition, or both, cooling in a desiccator, and weighing. When a new container is placed in service, special measures may be required to assure that it is brought to constant weight by the operations.

2.23 *Temperature* — Temperature values shall be expressed in degrees Celsius (°C).

2.24 *Water* — References to water in the testing procedures are understood to mean 18.2 Mohm-cm water that is of the appropriate grade for the intended purpose. Depending on the grade of chemical being tested, water meeting the requirements for Types E-1, E-1.1, and E-1.2 18.2 Mohm-cm water in ASTM Standard Guide D5127 may be used. In tests for nitrogen compounds, water should be “ammonia-free” or “nitrogen-free.” For some tests, freshly boiled water must be used in order to ensure freedom from material absorbed from the air such as ammonia, carbon dioxide, or oxygen.

2.25 *Water by Karl Fischer Titration* — The Karl Fischer method for the determination of water involves a titration with the so-called Karl Fischer reagent, consisting of iodine, sulfur dioxide, pyridine, and methanol. For most relevant chemicals intended for use in semiconductor manufacture and other electronics applications, the water content is small and electrometric detection of the end point is preferred. Details of this method are provided by ASTM E 203 and in *Reagent Chemicals*, published by the American Chemical Society.

2.26 *Water and Steam Baths* — A water bath, unless otherwise stated, shall imply a bath of vigorously boiling water. A steam bath (at 1 atmosphere pressure), unless otherwise qualified, shall imply either exposure to flowing steam or to another source of heat at the temperature of flowing steam.

2.27 *Weights and Measures* — The weights and measures used shall be, to the extent possible, those of the International System (SI), adopted by the General Conference of Weights and Measures of 1960. Some relevant quantities are listed below:

Physical Quantity	*Name*	*Symbol*	*Expression in SI Base Units*
length	meter	m	(base)
mass	kilogram	kg	(base)
time	second	s	(base)
electric current	ampere	A (See NOTE 1.)	(base)
amount of substance	mole	mol	(base)
electric conductance	siemens	S	$m^{-2} \bullet kg^{-1} \bullet s^{3} \bullet A^{2}$
electric potential difference	volt	V	$m^{-2} \bullet kg \bullet s^{-3} \bullet A^{-1}$
electric resistance	ohm	Ω	$m^{2} \bullet kg \bullet s^{-3} \bullet A^{-2}$
energy, work quantity of heat	joule	j	$m^{2} \bullet kg \bullet s^{-2}$
force	newton	N	$m \bullet kg \bullet s^{-2}$
frequency	hertz	Hz	s^{-1}
power, radiant flux	watt	W	$m^{2} \bullet kg \bullet s^{-3}$
pressure	pascal	Pa	$m^{-1} \bullet kg \bullet s^{-2}$
quantity of electricity, electric charge	coulomb	C	$s \bullet A$

NOTE 1: In this work, the ampere is abbreviated amp to avoid confusion with absorbance.

3 General Procedures and Guidelines to Certain Methods

3.1 *Guidelines for Assay by Wide Bore Column Gas Chromatography* — The theory of gas chromatography is given in many monographs, reviews, etc. The purpose here is to delineate some practical aspects for the assessment of volatile organic reagents by gas chromatography. A complete detailed procedure for the gas chromatographic assay is not given since available instruments vary from laboratory to laboratory.

However, the use of wide bore capillary columns is recommended to replace conventional packed columns. Capillary columns, constructed of fused silica onto which is bonded a liquid phase, have greater resolving power and chemical inertness.

3.1.1 *Equipment* — A standard gas chromatograph equipped with capillary wide bore column adaptors of isothermal and multi-step linear and temperature programmed operation is recommended.

3.1.2 *Sample* — Direct flash vaporization or on-column injection of the sample with standard gauge needles can be used with wide bore columns. On column injection can minimize sample degradation while increasing the reproducibility of results. On column injection is ideal to use with very volatile materials such as the reagents assayed in this monograph.

3.1.3 *Columns* — Many types of columns exist and can be used. Until recently, packed columns in which a liquid phase is coated on a porous solid support were extensively used for assay of reagents. The introduction of wide bore capillary columns having an i.d. of typically 530 microns and a thick film of liquid phase from 1 to 5 microns allows a laboratory to use a standard packed column instrument and conditions, while gaining the advantages of capillary technology.

Columns can be used either in the high resolution capillary mode (low carrier gas flow rates) to achieve optimum resolution of sample components, or at higher flow rates (20–30 mL/min) where they will perform packed column-like separations in a shorter time. Packed columns require a multitude of stationary phases to accomplish typical separations performed in an analytical laboratory. The increased length of capillary columns allows for better separation of components so that three columns of low (Type 1, METHYL SILICONE), moderate (Type 2, MIXED CYANO, PHENYL, METHYL SILICONE), and high (Type 3, CARBOWAX) polarity can handle the majority of analytical requirements. Columns which have been found acceptable for assay of the reagents in this manual are listed in Table 1.

3.1.4 *Conditions* — Appropriate conditions will vary from one gas chromatographic system to another. Conditions which have been found acceptable are listed under each individual standard. When using packed column in the isothermal mode, the temperature of the column is usually maintained at 10° to 20°C below the boiling point of the reagent. The efficient mass transfer associated with wide bore capillary columns may necessitate initial column temperatures to be more than 20°C below the boiling point of the reagent of interest. Temperature programming may be used to improve the shape of eluting peaks and to shorten analysis times. The remaining two heated zones (injector and detector) should be maintained at as low a temperature as possible to lessen thermal decomposition effects. Typically, for the injector this is 50°C above the boiling point of the material of interest; the detector is held 25°C above the highest temperature reached by the column, but never less than 100°C. The split or splitless mode of injection can be used depending on the chromatographic equipment available. The use of a wide bore capillary column simplifies conversion of a packed column to a capillary instrument.

3.1.5 *Detector* — Use of a thermal conductivity detector minimizes the need to correct for detector response to differences in chemical composition and is usually sufficient for determining reagent assay. To qualify trace impurities, the more sensitive flame ionization detector is recommended. The detector output, after amplification, is used to produce the chromatogram, a plot of component quantity versus elution time. Modern systems digitize the analog output, allowing direct printout of peak areas and retention times.

3.1.6 *Calculation of Results* — Results from a chromatogram, used to determine the assay of a reagent, are expressed in area percent normalized to 100%. A response factor correction for each component is required for the most accurate results, especially when the sample components differ markedly in their detector response. An internal standard reduces error due to variations in injection quantities, column, and detector conditions. The use of control charts, to aid the analyst in visualizing chromatographic variability, is suggested. To verify that assay results are valid, use of a system suitability test is recommended.

Table 1

Reagent	*Recommended[1] Column*	*Alternate[2] Column*
Acetone	III	II, I
n-Butyl Acetate	I	II
Dichloromethane	I	II
Methanol	I	
Methyl Ethyl Ketone	I	
2-Propanol	I	III
Tetrachloroethylene	I	
Toluene	I	III
Trichloroethylene	I	
Trichlorotrifluoroethane	I	
Hexamethyldisilizane[3]	I	
1-Methyl-2-Pyrrolidone	I	
1,1,1 Trichloroethane	I	

Type I Column — Methyl Silicon Bonded Phase
Type II Column — Mixed Cyano, Phenyl, Methyl Silicon Bonded Phase
Type III Column — Carbowax Bonded Phase
1. Satisfactory for both assay and SEMI-specified impurity determinations.
2. Column will separate all SEMI-specified impurities from assay component. Elution order will differ from typical given in individual reagent procedures.
3. Presilanized column recommended.

3.2 *Color*

3.2.1 *Color (APHA)* — For the rapid assessment of "colorless" liquids for contamination by colored materials, visual comparison with platinum-cobalt solution standards is appropriate, following the methodology of the American Public Health Association (APHA) established for the evaluation of the color of water.

3.2.2 *Preparation of Platinum-Cobalt Stock Solution (APHA No. 500)* — Dissolve 1.246 g of reagent grade potassium chloroplatinate, K_2PtCl_6, and 1.000 g of cobalt chloride hexahydrate, $CoCl_2 \bullet 6H_20$, in water. Add 100 mL of reagent grade hydrochloric acid (~37%) and dilute with water to exactly 1,000 mL. Store in a tightly closed bottle.

3.2.3 *General Procedure for "Color (APHA)" Test* — For the working standard, dilute one or more suitable aliquots of the Platinum-Cobalt Stock Solution (APHA

No. 500) with water to 100 mL. In 100 mL Nessler tubes, compare the working standard with an equal volume of the liquid under assessment. View each tube vertically over a white background. The color of the liquid should not exceed the maximum APHA standard value allowed by the specification for that liquid. On the dilution to 100 mL, aliquots of the stock standard of 1, 2, 3 . . . mL correspond to APHA 5, 10, 15, etc.

Table 2 Abbreviations and Signs

A	absorbance
Å	angstrom (s) [NOTE 1]
a.c.	alternating current
amp.	ampere(s) [NOTE 2]
addn.	addition [NOTE 3]
alc.	alcohol(ic) [NOTE 3]
amt.	amount [NOTE 3]
approx.	approximate(ly)
aq.	aqueous [NOTE 3]
atm.	atmosphere(s)
av.	average [NOTE 3]
b.p.	boiling point [NOTE 3]
ca.	circa (i.e., about or approximately)
cal.	calorie(s)
cc	cubic centimeter(s) (mL)
c.d.	current density [NOTE 3]
cm	centimeter(s)
cm^2	square centimeter(s)
compd.	compound [NOTE 3]
compn.	composition [NOTE 3]
concn.	concentration [NOTE 3]
d	density (or difference in statistical analysis)
d.c.	direct current
diam.	diameter [NOTE 3]
dil.	dilute [NOTE 3]
EDTA	ethylenediaminetetraacetate (i.e., [ethylenedinitrilo] tetraacetate)
equiv.	equivalent(s)
f.p.	freezing point [NOTE 3]
FW	formula weight
g	gram(s)
GC	gas chromatography (or chromatographic)
GLC	gas-liquid chromatography (or chromatographic)
hr.	hour [NOTE 3]
I.D.	inside diameter [NOTE 3]
insol.	insoluble [NOTE 3]
ir	infrared [NOTE 3]
kg	kilogram(s)
L	liter(s)
m	meter(s) or milli (10)
M	molar or molarity
ma	milliampere(s)
max.	maximum (or maxima)
meq	millequivalent(s)
mg	milligram(s)
min	minute(s)
min.	minimum
mixt.	mixture [NOTE 3]
mL	milliliter(s)
mm	millimeter(s)
mM	millimolar (or millimolarity)
mmol	millimole
mol	mole [NOTE 3]
m.p.	melting point [NOTE 3]
mv	millivolt(s)
mμ	millimicron(s) (=nm) [NOTE 4]
N	normal or normality
n	nano (10^{-9})
ng	nanogram(s)
nm	nanometer(s)
no.	number [NOTE 3]
O.D.	outside diameter [NOTE 3]
p	pico (10)
pg	picogram(s)
powd.	powdered [NOTE 3]
ppb	part(s) per billion (=ng/g or ng/mL) [NOTE 5]
ppm	part(s) per million (= μg/g or μg/mL)
ppt.	precipitate [NOTE 3]
prepn.	preparation [NOTE 3]
psi	pounds per square inch
PTFE	poly (tetrafluoroethylene) (e.g., Teflon®)
satd.	saturated [NOTE 3]
SCE	saturated calomel electrode [NOTE 3]
s	second(s)
sepn.	separation [NOTE 3]
soln.	solution [NOTE 3]
soly.	solubility [NOTE 3]
std.	standard [NOTE 3]
T	transmittance
temp.	temperature [NOTE 3]
TLC	thin-layer chromatography (or chromatographic)
titrn.	titration [NOTE 3]
UV	ultraviolet [NOTE 3]
v	volts [NOTE 3]
vol.	volume [NOTE 3]
W	watts [NOTE 3]
wt.	weight [NOTE 3]
μ	micron(s) (=μm) or micro (10) [NOTE 4]
μa	microampere(s)
μeq	microequivalent(s)
μg	microgram(s)

μL	microliter(s)
μm	micrometer(s)
μM	micromolar
μmol	micromole(s)
Ω	ohm(s)
°C	degrees Celsius
~	circa (about or approximately)
%	percent
>	greater than
≥	greater than or equal to
<	less than
≤	less than or equal to

NOTE 1: The angstrom does not conform to the SI program, and its use is restricted to emission spectrographic data (1 Å = 0.1 nm).
NOTE 2: The International System (SI) symbol, A, for ampere(s) is avoided, owing to possible confusion with absorbance.
NOTE 3: Abbreviation is not recommended for text, but only for formulas, equations, tables, specification statements and illustrations where brevity is required.
NOTE 4: The units micron and millimicron do not conform to the SI program, and the use of the equivalent terms micrometer (mm) and nanometer (nm), respectively, is recommended.
NOTE 5: A "billion" is interpreted differently in various countries and the term "parts per billion" is therefore not recommended by the International Union of Pure and Applied Chemistry (IUPAC). The term should only be used where it is defined parenthetically in the same text passage, e.g., as ng/g or ng/mL.

3.3 *Determination of Residue after Evaporation*

3.3.1 *Introduction* — The residue after evaporation is defined as the relative amount of residue remaining after evaporation of a sample of solvent followed by heating of the residue at 105°C for 30 minutes. Drying to constant weight is not utilized since protracted heating may lead to slow volatilization of high-boiling matter.

3.3.1.1 For the determination of the residue after evaporation at the level of 5 parts per million (μg/g) or below, determinate errors must be kept extremely small and random errors should be minimized. In the procedure given below, the positive error due to exposure to airborne particulate matter is reduced by the use of the closed system afforded by the Thiers assembly. Possible negative errors associated with losses caused by transfer of a concentrated sample or the residue are avoided by effecting the evaporation and weighing in a single dish. The determinate and random errors associated with the weighing operations are reduced by using an aluminum dish for most solvents, weighing on a semi-microbalance, eliminating any static electricity, and conducting all heating and cooling steps in a reproducible manner.

3.3.2 *Equipment* — The Thiers assembly is fashioned from a crystallizing dish. (See Figure 2.) The aluminum dishes of 250 mL capacity are prepared by cutting out a 30 cm circle of aluminum foil, rinsing it with the solvent, and, using gloves, pressing it around the base of an 800 mL beaker. The balance is a semi-micro type, and the static electricity eliminator is a low-level, radioactive type available from supply houses.

3.3.3 *Procedure*

3.3.3.1 Rinse the 250 mL aluminum dish (or platinum dish in the case of halogenated solvents) with a portion of the sample. Heat the dish at 105°C in an oven for 30 min and cool for 30 min (1 hr for platinum) in a desiccator charged with calcium chloride and placed near the balance. Discharge static electricity using the eliminator and weigh the dish on a semi-microbalance to the nearest 0.01 mg.

3.3.3.2 Start the flow of filtered nitrogen gas through the side arm of the Thiers assembly and place the dish inside. Raise the cover briefly to add the specified amount of solvent from a clean, graduated cylinder. Adjust the nitrogen stream so that the surface of the solvent is barely rippled. Also, adjust the heat lamp and hot plate so that the evaporation rate does not exceed 8 mL/min and that no sample condenses on the top inner surface of the assembly.

3.3.3.3 When all of the sample has evaporated, heat the dish for 30 min in an oven at 105°C. Cool as given above, discharge the static electricity, and reweigh. Calculate the residue as parts per million (ppm).

$$\frac{[\text{wt of dish plus residue (g) - wt of dish (g)}] \times 10^6}{\text{sample wt (g)}}$$

NOTE 1: For best results, room temperature should be kept constant to ± 5°C.

3.4 *General Procedure for Trace Arsenic (and Antimony) Determination*

3.4.1 *Introduction* — This photometric procedure is based upon the color reaction of silver diethyldithiocarbamate with arsine (and stibine). It provides for measurement of the absorbance of the sample and standards with subsequent calculation of the arsenic and antimony content of the sample, expressed as arsenic. The procedure given below differs from conventional ones by the omission of potassium iodide and stannous chloride. By this omission, antimony is evolved as stibine and reacts with the silver diethyldithiocarbamate solution. The color development is consequently due to both arsenic and antimony. The test sensitivity for arsenic is greater than for antimony.

3.4.2 *Apparatus* — The apparatus (see Figure 2) consists of a 125 mL arsine generator (a) fitted with a scrubber unit (c) and an absorber tube (e), with a 24/40 standard-taper joint (b) and a ground glass ball-and-socket joint (d), secured with a No. 12 clamp, connecting the units. In order to insure a more uniform rate of flow of gas into the absorbing solution, various modifications may be employed, such as the use of a fritted-glass disk sealed into the tapered end of the absorption tube.

3.4.3 *Reagents*

3.4.3.1 *Arsenic Stock Solution* — (1.00 mg/mL of arsenic) — Transfer 0.66 g of arsenic trioxide to a 500 mL volumetric flask and dissolve with 5 mL of 50% sodium hydroxide solution. Neutralize with 5 *N* sulfuric acid, add an excess of 5 mL, dilute to the mark with water, and mix thoroughly.

3.4.3.2 *Arsenic Working Solution* — (1.0 µg/mL of arsenic) — Transfer exactly 0.5 mL of the arsenic stock solution to a 500 mL volumetric flask, and 5 mL of 5 *N* sulfuric acid, dilute to the mark with water, and mix thoroughly. Prepare immediately before use.

3.4.3.3 *Lead Acetate Solution* — Dissolve 10 g of lead acetate trihydrate in 100 mL of water.

3.4.3.4 *Silver Diethyldithiocarbamate Solution* — Dissolve 1 g of diethyldithiocarbamic acid, silver salt, in 200 mL of pyridine and filter the solution. (The pyridine is best purified by passage through an alumina column.) Store this solution in a light-resistant container and use within 1 month. Silver diethyldithiocarbamate as a dry solid is yellow in color. Discard material that is markedly off color or develops a strong odor; alternatively, recrystallize from 1:1 pyridine-water and dry *in vacuo* at room temperature.

3.4.4 *Sample Solution Preparation* — Prepare the sample solution as specified in the procedures for the individual chemical.

3.4.5 *Procedure*

3.4.5.1 Treat the sample as described in the procedure for the individual chemical and transfer the resulting solution to the generator flask. Swirl the flask, add 5 mL of 20% sulfuric acid, and allow to stand at room temperature for 15 minutes.

3.4.5.2 Pack the scrubber tube (c) with two pledgets of lead acetate-impregnated glass wool previously moistened with lead acetate solution freed from excess solution by squeezing and dried in a vacuum. Allow a small space between the two pledgets. Place 3.0 mL of silver diethyldithiocarbamate solution in the absorber tube (e), add 3 g of zinc (granular) to the generator flask (a), and immediately connect the scrubber-absorber assembly to the flask.

3.4.5.3 Place the generator flask in a water bath maintained at 25° ± 3°C and swirl the flask gently at 10 minute intervals. (The addition of a small volume of 2-propanol to the generator flask may make the gas evolution more uniform.) After 45 minutes, disconnect the tubing from the generator flask, transfer the silver diethyldithiocarbamate solution to a 1 cm photometer cell, and measure the absorbance at 525 nm versus the water blank.

3.4.5.4 Carry a water blank and standard through the procedure, using the identical quantities of the same reagents. The standard consists of a volume of the arsenic working solution corresponding to the amount of arsenic stated in the procedure for the individual chemicals. Any red color in the silver diethyldithiocarbamate solution from the sample preparation should be no greater than that obtained with the standard.

3.5 *Guidelines for Determination of Trace Elements by Emission Spectrography* — For organic solvents, acids, and some other volatile chemicals used in semiconductor device fabrication, assessment of the contents of over twenty trace elements is required. For such purposes, dc-arc emission spectroscopy is the survey method of choice. The detection limits achievable can be improved by preconcentration of a large sample by volatilization. The loss of trace elements in this enrichment process can be reduced by the use of graphite as a collector and often by the presence of additives. The evaporation must be conducted under “clean air” conditions, and reliability should be assured by the frequent conduct of “blank” determinations. In this edition of “SEMI” Specifications and Procedures for electronic-use chemicals, no procedure for emission spectrography is included since the practices established and the spectrographic capabilities available vary from laboratory to laboratory. Some of the practical considerations involved, however, are delineated below.

3.5.1 *Spectrograph* — A grating instrument with photographic recording is required with sufficient resolution to separate the typical spectral lines of the elements listed in Table 3. In some laboratories, a 3 -meter instrument with a grating dispersion of 5.56 A per mm has proved satisfactory.

3.5.2 *Excitation Conditions* — A dc-arc emission source, total burn conditions, and a controlled atmosphere (70:30 argon-oxygen) are recommended. In this way, quantification for a single burn can be achieved for both easily volatilized and refractory elements. As the spectrographic emulsion, Kodak SA-1 or equivalent is recommended. As the electrodes, ASTM S-13 and C-8 types are used.

Table 3 Analytical Lines for Various Elements

Element	*Analytical Line Å*
Aluminum (Al)	3082.16
Barium (Ba)	3071.58

Element	Analytical Line Å
Boron (B)	2497.73
Cadmium (Cd)	3466.20
Chromium (Cr)	2835.63
Cobalt (Co)	3405.10
Copper (Cu)	3247.54
Gallium (Ga)	2943.64
Germanium (Ge)	3039.06
Gold (Au)	2675.95
Iron (Fe)	3020.64
Lithium (Li)	3232.61
Magnesium (Mg)	2852.13
Manganese (Mn)	2794.82
Nickel (Ni)	3414.76
Potassium (K)	3446.72
Silicon (Si)	2881.58
Silver (Ag)	3280.68
Sodium (Na)	3302.32
Strontium (Sr)	3464.46
Tin (Sn)	2839.99
Zinc (Zn)	3345.00

3.5.3 *Standards* — For the precision required, visual comparison with a set of standard plates suffices for most elements. Preferably a commercial seven-step multielement standard in graphite is employed having an internal standard such as indium incorporated. Even when densitometry is not used, inspection of the intensity of a line for the internal standard can assure that a significant portion of sample has not been lost mechanically. For an element not present in that standard (e.g., gold and palladium), the detection limit can be based on a literature value for total burn conditions in a graphite matrix.

3.5.4 *Evaporation of Sample*

3.5.4.1 In general terms, the sample size selected will depend on the detection limits required, the optics of the spectrograph used, and the excitation conditions. In many laboratories a sample weight of 50 to 100 grams is taken routinely. The evaporation in performed with 10 mg of spectrographic grade graphite added as a collector. An acid-leached Teflon evaporating dish is used, and the evaporation itself should be carried out under "clean air" conditions. These can be achieved either by use of the Thiers assembly (see Figure 2) or equivalent or within a "clean air" station fitted with a fume exhaust system. Where a 50 gram sample is used, the concentration factor is 5000; that is, the nominal values for the set of standards are divided by that number.

3.5.4.2 In the evaporation, additives may be present to improve the retention of some elements. In brief, a drop of sulfuric acid is added to hydrochloric and citric acids, and a crystal of oxalic acid to nonoxygenated solvents. The addition of mannitol is recommended in the evaporaiton of hydrofluoric and hydrochloric acids to retain boron and possibly tin and antimony.

3.5.5 *Remarks* — For further information on the evaporation and spectrographic assessment of acids, the paper of Kershner, Joy, and Barnard, *Appl. Spectroscopy*, 25, 542 (1971), may be consulted.

3.6 *Guidelines for Determination of Trace Elements by Atomic Absorption Spectrometry* — The principles of analysis by atomic absorption spectrometry are given in monographs. The purpose here is to describe in general terms how the technique should be used when specified in the procedures for an individual chemical to assure that the specifications for one or more stated elements are met. No general procedure is given since operating details will vary with instrument design; consequently, the manufacturer's manual should be followed.

3.6.1 *Equipment* — The source is a hollow cathode lamp, or equivalent, for the relevant element. The burner is slotted and will vary in design and path length according to the gas(es) to be used. The monochromator should have a resolution of at least 0.1 nm. The signal from the photomultiplier tube detector is read from a meter, digital display, or recorder tracing. A deuterium background corrector should available.

3.6.2 *Flame and Burner Conditions* — The flame gases to be used are specified in the procedure for the individual chemical. The burner position and gas flow rates should be optimized for a given determination.

3.6.3 *Solution Conditions* — The solutions are prepared as given in the procedures for the individual chemical.

3.6.4 *Working Standard Solutions* — Working standard solutions should be prepared on the day of use by dilution of a stock standard solution.

3.6.5 *Quantitation* — Commonly, the method of standard addition is employed. It is applicable at low concentrations where a linear relationship exists between signal and concentration. By this technique the standards have a matrix similar to the sample. It is essential that the sample solution, along with the additions, has absorbance in the range for which linearity is expected: routinely, 0.1 to 0.5 absorbance. The use of standard additions does not eliminate interferences, but assures that the element of interest behaves similarly in the sample preparation and those with additions. Background correction is usually required, and additives may be called for (see below).

3.6.5.1 For specific tests, the signals are measured for five solution preparations: the reagent blank (which may be only water), the sample solution, and three made by standard additions to the sample solution. The signal for the reagent blank preparation is subtracted from the signals for each of the four other preparations. These four signals are used graphically or mathematically to determine the content of the element in the sample. Where several elements are to be determined, they are added simultaneously to the third, fourth, and fifth preparations. Commonly, the additions correspond to one-half the specification limit, equal to the limit, and twice the limit.

3.6.5.2 A calibration line obtained for aqueous standards can be used if its slope and the slope of the standard addition line are identical. In that event, chemical (matrix) effects are negligible.

3.6.6 *Background Correction* — Where spurious absorption or other background correction is required, details are given in the procedure for an individual chemical. For an element with the stated resonance line in the ultraviolet region (< 350 nm), the correction should be performed with a deuterium discharge lamp. For an element with the stated line in the visible region (> 350 nm), the adjacent line technique should be employed. In this method, the background absorption is determined at a wavelength adjacent, ± 5 nm, to the line being used for the element of interest; that is, it is measured at a wavelength where significant atomic absorption by that element is absent.

3.6.7 *Additives* — Where additives are included in the solution preparations, including an ionization suppressant, details are provided in the procedures for the individual chemical.

3.6.8 *Remarks* — The manufacturer's manual should be consulted for details on the venting of burner gases and for safety precautions in the operation of the instrument and burner. The user should check the performance of an instrument from time to time to assure that adequate sensitivity is being attained for the needs of the particular determination.

3.7 *Guidelines for Determination of Trace Elements by Flame Emission Spectroscopy* — The principles of analysis by flame emission spectroscopy are given in many monographs. The purpose here is to describe in general terms how the technique should be used when specified in the procedures for an individual chemical to assure that the specifications are met for one or more stated elements (commonly sodium or potassium, or both). No general procedure is given since operating details will vary with instrumental design; consequently, the manufacturer's manual should be followed.

3.7.1 *Equipment* — The flame photometer should have a monochromator with a resolution of at least 1 nm. The detector should have a red-sensitive phototube, a filter to remove the sodium D-line for potassium determinations, and a photomultiplier. (Instruments having a photomultiplier specially sensitive to the potassium line do not need a red-sensitive phototube.) The slit width must be adjustable. A sensitivity control should be available. Also, the burner should have controls for adjusting its position and gas flow rates. The read-out device may be a meter, digital display, or recorder.

3.7.2 *Flame and Burner Conditions* — The flame gases to be used are specified in the procedure for the individual chemical. The burner position and gas flow rates should be optimized for a given determination.

3.7.3 *Solution Conditions* — The solutions are prepared as given in the procedures for the individual chemical.

3.7.4 *Standards* — A stock standard solution for each relevant element should be accurately prepared, usually at a concentration of 0.1% wt/vol, as given either in the procedure for the individual chemical or in Section 4. Working standard solutions should be prepared on the day of use by dilution of a stock standard solution.

3.7.5 *Quantitation* — Commonly, a single addition of standard is employed. It is applicable at low concentration where a linear relationship exists between signal and concentration. By this technique, the standard has a matrix similar to the sample.

3.7.5.1 The amount of standard to be added to the sample to make the standard solution is given in the procedures for the individual chemical, and corresponds to the specification value of the element being determined.

3.7.5.2 For specific tests, the signals are measured for the sample solution and the standard solution. The instrument is optimized with the standard solution at the wavelength specified. It is then zeroed with water, and the sample is aspirated into the flame and its signal read. Without changing the slit, the wavelength is changed to a nearby setting and the background value determined. The difference between the background value and the value for the sample should not exceed the difference between the values obtained for the sample and standard solutions.

3.7.6 *Remarks* — The manufacturer's manual should be consulted for details on the venting of burner gases and for safety precautions in the operation of the instrument and burner. The user should check the performance of the instrument from time to time to assure that adequate sensitivity is being attained for the needs of the particular determination.

3.8 *Guidelines for Use of a pH Meter* — The principles of pH measurement are given in monographs and instrument manuals. The purpose here is to describe in general terms how the technique is used with the procedures for individual chemicals, either to assure that a "pH of Solution" specification is met or to adjust the acidity or alkalinity of a solution as required in the conduct of a procedure.

3.8.1 *Equipment* — The pH meter should be capable of reading to 0.02 pH units and should best be equipped for temperature compensation. The electrodes should be calomel and glass and should be kept in appropriate solutions when not in use, following the supplier's recommendations.

3.8.2 *Standardization* — At time of use, the pH meter and electrodes should be standardized against two pH standard buffers that preferably should bracket the expected pH of the solution to be measured. The meter with the electrodes immersed in the first buffer should be adjusted to the stated value for that buffer. The electrodes should then be rinsed, and the meter, with the electrodes immersed in the second buffer, should be adjusted to the stated value for that buffer. This adjustment procedure should be repeated until two consecutive measurements for one of the buffers gives the same value within ± 0.02 pH units. Where a temperature is specified for an individual chemical, either as part of the specification parameter or the relevant procedure, that temperature should be maintained in the standardization with the corresponding assigned pH values for the pH standard buffers being employed. During measurements, each buffer should be magnetically stirred at the same constant rate.

3.8.3 *Quantitation* — For the measurement of the pH of a solution, the meter and electrodes should be standardized as given above. The electrodes should then be rinsed with water and immersed in the solution (held at the specified temperature), and the pH read once the reading has stabilized. The solution should be magnetically stirred at the same rate as used in the standardization. If the reading does not stabilize within 1 minute, the cause should be found and eliminated. Any water used to dilute a sample for the "pH of Solution" test should be carbon dioxide-free.

3.9 *Calibration and Measurement Method for Particles in Liquids* — This standard describes the apparatus and methods used to calibrate optical particle counters (OPCs) and to count hard particles in liquid reagents. The procedures in this standard provide a means of comparison of particle levels in various reagents using pressurized sampling and counted using the various available instruments. While the procedures in this standard are primarily directed at off-line sampling or sampling from containers, OPCs can also be used for continuous on-line particle measurement. While some substantial technical difficulty may accompany the implementation of the pressurized sampling technique for containers of more than 10 L, the method should be followed as closely as possible to maximize the integrity of the data. The following procedures are partially based on the publications in the attached bibliography which should be consulted for further details.

3.9.1 *Apparatus* — The apparatus used to measure the concentration of particles in reagents is comprised of a sample supply system, a particle counter, and a flow measurement and control system. Two manual flow measurement and control systems are presented in Figures 4 and 5. Several manufacturers have developed automated pressurized sampling systems.

3.9.2 *Discrete Sample Supply System* — In the method specified in this standard, the pressure in the reagent container is raised sufficiently above atmospheric pressure to produce the required flow and to reduce microbubble formation, which causes falsely high counts. Pressurizing containers of reagents presents a substantial safety hazard. Several systems have been developed for pressurizing the contents of a reagent container without placing a pressure differential across the reagent container wall. A pressurized sampling system is required for all reagents.

3.9.2.1 The reagent container is placed in a canister suitable for use as a pressure vessel at 4 bar (60 psi), such as a large steel filter housing. The interior of the canister should be resistant to corrosion by the reagents being tested. This canister is fitted with a relief valve set at 3.5 bar (50 psi), a nitrogen inlet, and a sealed feed-through for the sample tube. The reagent container is fitted with a perfluoroalkoxy (PFA) cap to which is attached a hydrophobic polytetrafluoroethylene (PTFE) nitrogen inlet filter. This permits the nitrogen pressures inside and outside the reagent container to equilibrate when the vessel is pressurized and prevents particles from the pressure canister from entering the sample reagent container.

3.9.2.2 Either of two sample and dip tube configurations may be used. In the first, a PFA dip tube, which extends to 5 cm from the bottom of the reagent container, is attached to the cap. The sample tube, which consists of a single continuous piece of PFA tubing to reduce the chance of incidental contamination during measurement, is connected to the cap and the particle counter. This configuration has the advantage that it allows the sample tube to be disconnected from the cap and dip tube, reducing the risk of splashing and of cross-contaminating samples. The disadvantage of placing a fitting between the sample and the counter is that the fitting may compromise the integrity of the sample.

3.9.2.3 In the second configuration, a single tube, without valves, fittings, or discontinuities extends from the counter, through the cap to 5 cm from the bottom of the reagent container. This has the advantage that it ensures the integrity of the sample but the disadvantage is that the risk of splashing and cross-contamination is increased.

3.9.3 *Particle Counter* — Laser light scattering OPCs from any of several suppliers may be used provided they are in calibration, and used subject to the limitations described in Section 3.9.3.1.

3.9.3.1 *Limitations on Counting Particles in Liquid Reagents using OPCs* — OPCs are calibrated using polystyrene latex (PSL) beads suspended in high-purity water. The optical properties of naturally occurring particles in liquid reagents are different from the optical properties of PSL and water. OPCs detect "light-scattering centers" and calculate particle size and concentration based on the assumption that the light-scattering centers are equivalent to PSL in water. In reality, light scattered by a particle is dependent upon particle size, particle shape and the difference between the particle's refractive index and the refractive index of the surrounding medium. When properly calibrated OPCs from different manufacturers are used to measure particles in high-purity water, they give comparable size and concentration data.

3.9.3.1.1 Commercially, OPCs are manufactured with different illuminating wavelengths and a variety of optical arrangements for collecting light scattered by particles. Because of the significant difference in the refractive index of particles relative to the refractive index of water, the resulting scattered light profile is readily detected by all OPCs. Hence there is relatively good comparative agreement between OPCs when used to detect particles in high-purity water.

3.9.3.1.2 When calibrated OPCs are used to measure particles in semiconductor liquid reagents, a totally different situation is encountered. The refractive index of liquid reagents varies significantly from water and is, in general, greater than water. While the refractive index of reagents is known and can be adjusted for, the refractive index of particles is unknown and, in many circumstances, is expected to be very close to the refractive index of reagents. Particles therefore have a tendency to become invisible to an OPC. The degree of invisibility will depend on the optical arrangement of each OPC. A study carried out in 1999[2] found that particle concentrations reported by different sensors varied significantly. Chemical-to-chemical comparison indicated that there was no sensor that consistently reported higher or lower concentrations than other sensors.

3.9.3.2 *Using OPCs in Semiconductor Liquid Reagents* — OPCs have a critical role to play in monitoring particles in liquid reagents. OPCs can detect low concentrations of small particles in real-time and can be easily calibrated using PSL beads. However, the current state of OPC technology limits their use to claim that a liquid reagent meets a standard particle concentration at a particular particle size.

3.9.3.2.1 When a supplier of a liquid reagent uses an OPC to specify that reagent's particle concentration, for example on a Certificate of Analysis, the make and model of OPC must also be specified. If the customer of the liquid reagents wishes to check whether the incoming reagent meets the claimed level of cleanliness, the customer must use an OPC of the same make and model number. However, it has also been shown that even two calibrated "identical" OPCs can differ by 10–20% when measuring particles in liquid reagents.

3.9.4 *Flow Control and Measurement System* — A discrete or a continuous method may be used to control and measure the flow of the sample through the particle counter. In both procedures, a needle valve, downstream of the counter, is used to control the flow rate. In the discrete procedure, a measured volume of fluid is counted and collected in a graduated container. Automatic level detection may be used to start and stop the counter. In the continuous procedure, the flow rate is set and the count is accumulated for a measured time period.

3.9.5 *Calibration* — Each particle counter (sensor and signal analysis unit) must be calibrated at least once every twelve months.

3.9.5.1 It is recommended that the calibration be performed by the instrument manufacturer or a metrology laboratory certified by the instrument manufacturer. Calibration is performed by counting polystyrene latex (PSL) beads suspended in water. PSL beads of known size (characterized by transmission electron microscopy -TEM) and concentration (characterized by a scanning electron microscope -SEM) must be used. In addition most instrument manufacturers use a working standard or "gold

2 Carrieri, D., D.C.Grant and W.Kelly, "A Comparison of Optical Particle Sensors Used to Measure Particle Concentration in High-Purity Process Chemicals" Proceedings SEMICON West 1999

standard" OPC as a reference against which all OPCs of the same Model are compared.

3.9.5.2 The determination of size correction factors for particle counters is not recommended. Particle counters should be calibrated with PSL beads in accordance with the manufacturer's recommendation.

3.9.6 *Coincidence Correction Factors* — The determination of coincidence correction factors for particle counters is not recommended. Particle counters should be calibrated with PSL beads as per the manufacturer's recommendation. Coincidence correction factors are only valid for monodispersed concentration of particles.

3.9.7 *Efficiency Correction Factors* — The determination of efficiency correction factors for particle counters is not recommended. Particle counters should be calibrated with PSL beads as per the manufacturer's recommendation.

3.9.8 *Monthly Check* — It is desirable to check the OPCs size calibration once a month. PSL beads of known size and approximate concentration can be purchased from several suppliers. Prepare a stock suspension of a combination of about 10^7 particles/L of each of the three sizes of PSL beads. Several solutions have been found to provide acceptably stable suspensions. Among them are: 25:1 ethanol/:water, and water with 0.01% surfactant and 0.05% bactericide. Dilute 10 mL of stock suspension to 1 L and measure the particle concentration using the procedure specified for reagents. If the results of this check are not within 10% of the expected PSL bead size, the OPC shall be recalibrated.

3.9.9 *Measurement Procedure*

3.9.9.1 *Setup* — Gently invert the sample reagent container three times to homogenize the particle distribution, then set it aside for 30 minutes to remove the bubbles formed during mixing. Under no circumstances must the sample reagent container be vigorously shaken or sonicated as this would generate numerous particles.

3.9.9.2 The smallest particle counter threshold should deliver at least 50% particle counting efficiency at the control size limit. The control size limit is the particle size agreed upon between supplier and customer that represents an acceptable size level. In general this size will be between 0.1 and 0.5 µm.

3.9.9.3 Attach the cap with the gas inlet filter and sample tube to the reagent container to be sampled. Place the reagent container in the canister, and seal the canister so that it may be pressurized. With the sample flow control valve open, gradually (< 3 bar/min) pressurize the sample to 3 bar for H_2O_2 and NH_4OH or as necessary to obtain the required flow for other fluids. Allow at least 250 mL of the sample to pass through the sensor before counting.

3.9.9.4 For each sample, after 5 aliquots have been measured, perform a chi-squared test to determine if the data are statistically valid. If the chi-squared test fails, examine the apparatus for defects, such as loose or cracked fittings, repair as necessary, and repeat the counting of 5 aliquots. If the sample fails both the second and third chi-squared tests, it is considered to be immeasurable and should be discarded. If a second sample gives similar results, the apparatus, including the OPC, may be defective and should be checked with a well-characterized sample and repaired if necessary.

3.9.10 *Measurement*

3.9.10.1 *Discrete Sampling* — Measure multiple aliquots of the same sample. The flow rate must be the same as that at which the instrument was calibrated.

NOTE 2: The statistical significance of any count data must be taken into consideration. Some OPCs inspect as little as $1/1000^{th}$ of the available sample flow, and may require a greater number of aliquots and larger sampling volume to ensure good statistics. For example, to obtain a coefficient of variation (standard deviation/mean) of 10%, it is necessary that at least 100 particles greater than the control size limit be counted.

3.9.10.2 *Continuous Sampling* — If continuous sampling apparatus is being used, adjust the needle valve on the rotameter to obtain a flow rate consistent with the instrument manufacturer's recommendations. This flow rate must be the same as that at which the instrument was calibrated. Correct the indicated value for the effect of the fluid density and viscosity on the rotameter reading. Allow the first minutes' fluid to flow to drain, then count the particles in each of five, 15 second intervals.

NOTE 3: The statistical significance of any count data must be taken into consideration. Some OPCs inspect as little as $1/1000^{th}$ of the available sample flow, and may require a greater number of aliquots and larger sampling volume to ensure good statistics. For example, to obtain a coefficient of variation (standard deviation/mean) of 10%, it is necessary that at least 100 particles greater than the control size limit be counted.

3.9.11 *Shutdown* — As in all portions of this procedure, appropriate safe chemical handling practices must be used. In particular, attention should be paid to the reactions between different reagents and between reagents and diluents, including water, and to the inherent hazards of these materials.

3.9.11.1 After the measurement has been completed, vent the pressure vessel to atmospheric pressure through an appropriate scrubber or exhaust hood, then flush the vessel with nitrogen to remove residual reagent vapors.

3.9.11.2 Flush the OPC and sample system with water or an appropriate solvent to remove the remaining fluid.

3.9.12 *Coincidence and Efficiency Corrections* — The determination of coincidence and efficiency correction factors for particle counters is not recommended. If an OPC's maximum concentration is exceeded, a different OPC should be selected, or the sample diluted. However any sample dilution will impose additional error and is not recommended.

3.9.13 *Index of Refraction Correction* — The determination of an index of refraction correction factor for particle counters is not recommended, as the refractive index of the contaminating particle is unknown.

3.10 *Guidelines for Determination of Trace Elements by Plasma Emission Spectrometry* — The principles of analysis by Plasma Emission Spectrometry are given in many monographs. The purpose here is to describe in general terms how the technique should be used when specified in the procedures for an individual chemical to assure that the specifications for one or more stated elements are met. No general procedure is given since operating details will vary with instrument design; consequently, the manufacturer's manual should be followed.

3.10.1 *Equipment* — A grating instrument with sufficient resolution to separate the typical spectral lines of the elements stated in the specification for an individual chemical. The signal from the detector is processed by a computer system and displayed on a recorder with graphics capability. A background correction technique is required.

3.10.2 *Operating Conditions* — Sensitivity, instrumental detection limit, precision, linear dynamic range, and interference effects must be investigated and established for each individual analyte line on that particular instrument. Types of interferences other than the simple overlap of a concomitant line on an analyte line must be considered.

3.10.3 *Solution Conditions* — The solutions are prepared as given in the procedures for the individual chemical.

3.10.4 *Working Standard Solutions* — Working standard solutions should be prepared on the day of use by dilution of a stock standard solution. For best results, standards should be matrix-matched.

3.10.4.1 Multi-element standards may be prepared. The components should be selected to provide stable standards within the required concentration range.

3.10.5 *Quantitation* — Commonly, the samples are measured against matrix-matched calibration standards; however, whenever a new or unusual matrix is encountered, the method of standard addition is employed. The standard addition does not detect coincident spectral overlap; an alternate wavelength or an alternate method is recommended for verification.

3.10.5.1 A calibration obtained with aqueous standards may be used if its slope and the standard addition method slope are identical.

3.10.5.2 *Evaporation of Sample* — The detection limits achievable can be improved by preconcentration of a large sample by evaporation. Through volatilization there may be a loss of trace elements, and recovery study data must be obtained. The loss of trace elements in this enrichment process can be reduced, often by the presence of additives. The evaporation must be conducted under "clean air" conditions, and reliability should be assured by use of a "blank" or control sample determination. The sample size will depend on the detection limits required and the capability of the instrument used.

3.10.6 *Background Correction* — A background correction technique is required for variable background contribution to the determination of trace elements. The correction interval should be selected such that the intensity of the background at that wavelength is equal to the background intensity under the analyte peak.

3.10.7 *Additives* — The procedures for the individual chemical will provide detailed instructions for required additives in the sample solution.

3.10.8 *Remarks* — The manufacturer's manual should be consulted for proper use of the instrument. The user should check the performance of the instrument from time to time to assure that adequate sensitivity is being attained for the needs of the particular determination.

Table 4 Suggested Plasma Emission Analytical Lines

Element		*Line*
Aluminum	(Al)	396.15
Barium	(Ba)	455.40
Beryllium	(Be)	313.04
Bismuth	(Bi)	223.06
Boron	(B)	249.77
Cadmium	(Cd)	214.44
Calcium	(Ca)	393.27
Chromium	(Cr)	205.55
Cobalt	(Co)	228.63
Copper	(Cu)	324.75
Gallium	(Ga)	294.36
Germanium	(Ge)	209.43
Gold	(Au)	267.60
Iron	(Fe)	238.20
Lead	(Pb)	220.35
Lithium	(Li)	670.78
Magnesium	(Mg)	279.55
Manganese	(Mn)	257.60
Molybdenum	(Mo)	202.02
Nickel	(Ni)	231.60
Niobium	(Nb)	309.42
Potassium	(K)	766.49
Silicon	(Si)	212.41
Silver	(Ag)	328.07
Sodium	(Na)	589.59
Strontium	(Sr)	407.77
Tantalum	(Ta)	240.06
Thallium	(Tl)	276.79
Tin	(Sn)	189.99
Titanium	(Ti)	334.94
Vanadium	(V)	292.40
Zinc	(Zn)	213.86
Zirconium	(Zr)	343.82

NOTE 4: The following guideline will replace Section 3.1 of this standard when all assay methods for existing specifications have been reviewed.

3.11 *Guidelines for Determination of Various Ions by Ion Chromatography* — The theory of ion chromatography is given in many monographs, reviews, etc. The purpose here is to delineate some practical aspects for the determination of various ions by Ion Chromatography. A complete detailed procedure for the ion chromatographic determination is not given since available instruments vary from laboratory to laboratory.

3.11.1 *Equipment* — A standard ion chromatograph equipped with ion suppression is recommended. Single column ion chromatography can also be used. The choice of reagents and columns is determined by the ions of interest.

3.11.2 *Sample* — Sample preparation varies depending upon the matrix effects of the chemicals being analyzed. Standard sample preparation techniques that may be used are (this list is not all inclusive):

- Evaporation of the reagent to remove the matrix and then diluting the residual with the appropriate grade of 18.2 Mohm-cm water that meets ASTM Standard Guide D5127,
- Diluting the reagent with the appropriate grade of 18.2 Mohm-cm water that meets ASTM Standard Guide D5127 to lessen the matrix effects, and
- Direct injection of the reagent.

3.11.3 *Columns* — Many types of columns exist and can be used. Typical selection criteria for columns consist of ion or ions of interest, the matrix of the reagent and eluent to be used.

3.11.4 *Conditions* — Appropriate conditions will vary from one ion chromatographic system to another. Conditions which have been found acceptable using ion suppression are listed under each individual standard. The two broad classifications of ions are anions and cations. A typical eluent used in the analysis of anions by ion suppression is a sodium carbonate and sodium bicarbonate in a solution with the appropriate grade of 18.2 Mohm-cm water that meets ASTM Standard Guide D5127. A typical eluent used in the analysis of cations is a dilute solution of hydrochloric acid in a solution with the appropriate grade of 18.2 Mohm-cm water that meets ASTM Standard Guide D5127.

3.11.4.1 Eluent concentration, eluent flow rate, and system pressure are variables which affect the chromatography. Each must be determined for the chromatographic system being used.

3.11.5 *Detector* — A conductivity detector is used to monitor the changes in the eluent conductivity due to ions in the sample. An ultraviolet absorbance detector can be used for detection of some ions. The detector output, after amplification, is used to produce the chromatogram, a plot of component quantity versus elution time. Modern systems digitize the analog output allowing direct printout of peak heights, peak areas, and retention times.

3.11.6 *Calculation of Results* — Ion Concentration =

$$\frac{(\text{Pk. Ht. S}_I - \text{Pk. Ht. B}_I)(\text{Conc. of Std}_I)}{\text{Pk. Ht. Std}_I - \text{Pk. Ht. B}_I} \times \text{Dilution Factor}$$

Pk. Ht. S_I = Peak Height of Sample Ion

Pk. Ht. B_I = Peak Height of Blank Ion

Pk. Ht. Std_I = Peak Height of Standard Ion

Conc. of Std_I = Concentration of Standard Ion

Peak area may be used instead of peak height. Calibration linearity must be established before use.

3.12 *Guidelines for Determination of Trace Elements by Graphite Furnace Atomic Absorption Spectroscopy* — The principles of analysis by Graphite Furnace Atomic Absorption Spectroscopy are given in numerous monographs. The purpose here is to describe in general terms how the technique should be used when specified in the procedures for an individual chemical to assure that the specifications for one or more stated elements are met. No general procedure is given since operating details will vary with instrument design; consequently, the manufacturer's manual should be followed.

3.12.1 *Equipment* — The source is a hollow cathode lamp, or equivalent, for the relevant element. The furnace will contain a pyrolytic coated graphite tube that has been conditioned according to manufacturer's instructions. The monochromator should have a resolution of at least 0.1 nm. The signal from the photomultiplier tube detector is read from a meter, digital display, or recorder tracing. Zeeman or deuterium background correction can be used. An autosampler is suggested in order to obtain better reproducibility.

3.12.2 *Operating Conditions* — Use an acceptable flow rate (300 mL per minute) argon as the inert carrier gas, with no flow during the atomization portion of the program. The temperature programs outlined by the instrument manufacturers should be checked using known standards, and adapted as necessary for optimum performance for a specific instrument. Calibrate the temperature controller for the different atomization temperatures used for each element. The conditions for iron, potassium, calcium, and sodium are included in Table 5.

Table 5

Element	*Iron*	*Potassium*	*Calcium*	*Sodium*
Wavelength (nm)	248.3	766.5	422.7	589.1
Bandwidth (nm)	0.2	1.4	2.0	0.2
Current (mA)	30	6	8	8
L'vov Platform?	Yes	Yes	Optopma;	Yes
Sample Size (μL)	20	10	10	10

3.12.3 *Solutions Conditions* — The solutions are prepared as given in the procedures for the individual chemical. All solutions will be prepared in a clean environment as defined in the SEMI guidelines.

3.12.3.1 *Working Standard Solutions* — Working standard solutions should be prepared on the day of use by dilution of a stock standard solution.

3.12.3.2 *Sample Preparations* — Sample preparation will be analyzed neat, with pre-concentration, or by dilution, according to the individual procedure.

3.12.3.3 *Quantification* — Results shall be reported as the result of three replicate analyses. Each replicate is the result of an 8-second integration of the peak area with the instrument in concentration mode. Recording should commence 5 seconds before the atomization, and baseline should be established 2 seconds prior to atomization. Reading should commence 1 second prior to atomization. Alternate integration schemes for the analytical peak shall be performed in a manner that captures all of the signal, as appropriate for the instrument.

3.12.4 *Calibration* — Calibrate the instrument using a standard prepared in the appropriate grade of 18.2 Mohm-cm water that meets ASTM Standard Guide D5127, over a concentration range appropriate for the analysis. The blank must also be contained in the appropriate grade of 18.2 Mohm-cm water that meets ASTM Standard Guide D5127.

3.13 *Guidelines for the Determination of Trace Elements by Inductively Coupled Plasma Mass Spectrometry* — The determination of trace elements in process chemicals which are commonly used in advanced semiconductor manufacturing requires a sensitive technique with the ability to perform simultaneous analysis for multiple elements. For such analyses, inductively coupled plasma mass spectrometry is the survey method of choice. Achievable detection limits are adequate for sample analysis with little sample preparation prior to analysis. Chemical matrix reduction needed to perform routine analysis is often achieved by dilution of the sample. Water used for dilution should be the appropriate grade of 18.2 Mohm-cm water that meets ASTM Standard Guide D5127. Matrix removal methods which require sample evaporation should be performed under HEPA filtered air such that reproducible blank samples are obtained at or less than one half the specified limit of trace elements for the sample. No specific procedure for inductively coupled plasma mass spectrometry is included since instrumentation and practices vary among laboratories. Some practical considerations relevant to the method are outlined below.

3.13.1 *Mass Spectrometer* — A mass spectrometer with a resolution of at least 1 amu at 5% of peak height is required to allow sufficient isotopic analysis over the entire mass range from 5 to 250 amu.

3.13.2 *Sample Introduction* — Conventional glassware used for sample introduction is in most cases appropriate for process chemical analysis. Process chemicals containing hydrofluoric acid require a special introduction system unless the hydrofluoric acid matrix is removed prior to the analysis.

3.13.3 *Ionization Source* — An inductively coupled plasma using argon as the support gas has proven to be satisfactory as a ionization source for the method. Ionization conditions present in the argon plasma are highly dependent on the various argon gas flow rates used to support the plasma. Sample introduction techniques used to induce the sample into the plasma are important to the analysis of the samples and must be optimized to allow successful analysis. In particular, sample uptake and nebulizer gas flow require special attention and should be treated carefully in order to optimize instrument performance for each of the various process chemicals.

3.13.4 *Evaporation of Samples* — Several of these chemicals require that the chemical matrix be removed in order to achieve good instrument performance and eliminate the problem of mass spectral interferences which occur either in the argon plasma, or are resultant from the plasma sampling process. If no steps are taken to remove the chemical matrix, severe problems will occur with the analysis of several important elements such as titanium, zinc, vanadium, and magnesium. For more information on the evaporation of samples, see Section 3.5.4 "Evaporation of Sample" in the general procedures.

3.13.5 *Solution Conditions* — The solutions are prepared as given in the procedures for the individual chemicals or elements.

3.13.6 *Working Standard Solutions* — Working standard solutions are prepared daily by dilution of stock standard solutions. The internal standard solutions are prepared similarly.

3.13.7 *Quantification* — Commonly, standards and samples are matrix matched to assure that plasma conditions during the analysis are similar for both standards and samples. This is often done by the use of ultrapure reagent chemicals in the preparation of the working standard solutions. For those chemicals which require matrix removal, the preferred matrix after preparation is dilute nitric acid (typically 1–3%.) The working standard solutions are prepared to cover the expected range of trace element concentration which is routinely from 0.0 to 20.0 ng/mL for process chemicals specified in this book. Background correction by use of a reagent blank solution is required for sample analysis by this technique.

3.13.7.1 An internal standard (such as indium or rhodium) must be used during the analysis.

3.13.8 *Remarks* — The manufacturer's manual should be consulted for details specific to the operation of the instrument. Performance checks on the instrument should be made from time to time to assure adequate mass resolution, performance, and sensitivity.

3.14 *Method Validation* — Analytical methods for trace metals or trace anions, require that performance parameters be assessed and compared to the standard and guideline requirements. The following performance parameters should be reviewed and reported with each method:

- accuracy
- precision measures
- interferences

3.14.1 *Accuracy*

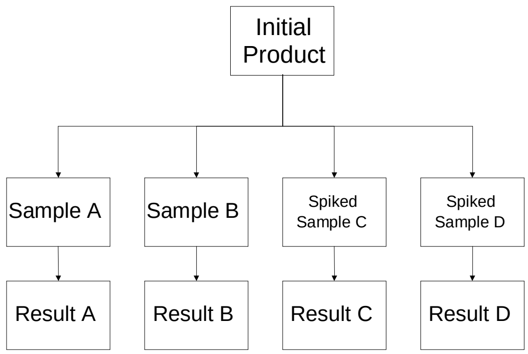
3.14.1.1 Method accuracy is a figure of merit that compares the data generated from the determined concentration of a sample to its "known" concentration. In some cases, a traceable standard may not be available and a "best available standard" may be substituted.

3.14.1.2 Determine the accuracy of a test method by utilizing a standard reference material as a sample and analyze it using the proposed test method. Report the test method accuracy as percent (%) bias:

$$\%\ \text{bias} = \frac{X_{\text{"found"}} - X_{\text{"true value"}}}{X_{\text{"true value"}}} \times 100$$

3.14.1.3 If no suitable traceable standard exists for the “true value,” describe the procedures used to qualify the “best available standard.”

3.14.1.4 Spiked recovery determinations are used to make a limited assessment of accuracy. Method validation is based on the analysis of a minimum of two samples and a minimum of two spiked samples (Figure 1).



NOTE: Samples A, B, C, and D are originally from the same initial product.

Figure 1
Data Collection Structure

3.14.2 *Precision Measures*

3.14.2.1 Typically a repeatability and reproducibility study is done, where samples are analyzed over a period of multiple days.

3.14.2.2 Measures of Method Precision target incorporation of all major method variability sources (such as sample preparation, calibration, and instrumental performance) into their definitions. A limited assessment of method precision is provided by both the % Recovery Range and the Method Detection Limit (Tables 6 and 7).

3.14.2.3 Measurement Repeatability targets how well measurements can be repeated and should be reported as percent (%) relative standard deviation (Tables 6 and 7).

3.14.3 *Interference Checks*

3.14.3.1 List all interferences that were examined during the course of method validation. Also note any known potential interferences.

3.14.4 *Data Reporting Requirements*

3.14.4.1 Table 6 along with Figure 1 illustrates the minimal data structure and analysis required to support method validation.

Table 6 Data Reporting Requirements

Sample A	Result A
Sample B	Result B
Average	Average of Result A and B
Spike	The amount of spike equivalent to 50% of the specified value for trace impurity, and it should be added to the sample prior to any sample preparation (ex., sample dilution, evaporation, etc.)
Spike Sample C	Result C
Spike Sample D	Result D
Recovery 1	Result C – Average
% Recovery 1	(Recovery 1 / Spike) × (100)
Recovery 2	Result D – Average
% Recovery 2	(Recovery 2 / Spike) × (100)
Average % Recovery	(% Recovery 1 + % Recovery 2) / 2
% Recovery Range	Max. % Recovery – Min. % Recovery
Result Standard Deviation	When applicable, report the Std. Dev. of multiple measurements for each Result
Relative Standard Deviation	When applicable, report the Relative Std. Dev. of multiple measurements for each Result

3.14.4.2 In cases where more samples are measured, statistical quantities analogous to the above should be constructed. For methods where automatic consecutive measurements can be obtained from the instrument, Results A, B, C, and D should be the mean of five or more instrumental measurements.

3.14.5 *Summary of Criteria for Success* — The success of the criteria for each figure of merit depends on the specification, the matrix of the analyte, and levels of detection required.

Table 7 Method Success Criteria

Figure of Merit	*Criteria for Successful Method*
Accuracy Spiked Recovery Study	 75–125% Spiked Recovery for each spiked sample.
Method Precision Spiked Recovery Study	 % Recovery Range less than or equal to 35%.
Measurement Precision	Maximum RSD = 20% of the concentration of each spiked sample where: $\text{RSD} = \frac{\text{Std. Dev. Result}}{\text{Conc. of Spiked Sample}} \times 100$
Method Detection Limit	As per SEMI C10: *Guide for Determination of Method Detection Limits*; Method Detection Limits can not exceed the specification.
Interference Checks	If interferences were examined or potential interferences exist, list them.

3.14.6 *Applicability to Existing Specifications* — The current implementation of Method Validation only applies to new or revised specifications. Any prior method validated by SEMI to support a given specification still remains applicable to that specification.

3.14.7 *Example* — Suppose that repeat measurements from four samples; A, B, C and D were available as follows:

Sample A: 0.19, 0.21, 0.25, 0.15, 0.23

Sample B: 0.31, 0.21, 0.17, 0.22, 0.26

Spiked Sample C: 0.83, 0.62, 0.76, 0.79, 0.80

Spiked Sample D: 0.77, 0.87, 0.69, 0.83, 0.84

Table 8 illustrates the calculations required as per Table 6.

Table 8 Data Reporting Example

Sample A	(0.19 + 0.21 + 0.25 + 0.15 + 0.23) / 5 = 0.206
Sample B	(0.31 + 0.21 + 0.17 + 0.22 + 0.26) / 5 = 0.234
Average	(0.206 + 0.234) / 2 = 0.220
Spike	The spike level is to be ½ the relevant specification. If the specification is 1 ppb, then the spike would be 0.5 ppb.
Spike Sample C	(0.83 + 0.62 + 0.76 + 0.79 + 0.80) / 5 = 0.760
Spike Sample D	(0.77 + 0.87 + 0.69 + 0.83 + 0.84) / 5 = 0.800
Recovery 1	(0.760 – 0.220) = 0.540
% Recovery 1	(0.540 / 0.5) = 108
Recovery 2	(0.800 – 0.220) = 0.580
% Recovery 2	(0.580 / 0.5) = 116
Average % Recovery	(108 + 116) / 2 = 112
% Recovery Range	(116 – 108) = 8
Result Standard Deviation	Since repeat measurements were available in this example, report the sample standard deviations. Sample A: 0.038 Sample B: 0.053 Sample C: 0.082 Sample D: 0.071
Relative Standard Deviation (as a %)	Since repeat measurements were available in this example, report the relative sample standard deviations. Samp. A: 100 × (0.038 / 0.220) = 17.5 Samp. B: 100 × (0.053 / 0.220) = 24.2 Samp. C: 100 × (0.082 / 0.720) = 11.4 Samp. D: 100 × (0.071 / 0.720) = 9.9 Note use of the average of 0.220 and the sum of the average + spike (0.720) above.

This example provided the data for the first three success criteria found in Table 7 as well as providing other required summary statistics. Table 9 summarizes performance relative to the success criteria.

Table 9 Method Success Criteria

Figure of Merit	*Criteria for Successful Method*
Accuracy	Both Recovery 1 (108%) as well as Recovery 2 (116%) were in the required 75–125% Spiked Recovery range.
Method Precision	The % Recovery Range was 8% and met the requirement of not exceeding 35%.
Measurement Precision	Maximum RSD for the spiked recoveries was 11.4% which is less than the maximum allowable 20%. Note that the RSDs calculated for Samples A and B are not relevant for this requirement.
Method Detection Limit	Not illustrated in this example, an example is provided with SEMI C10. The Method Detection Limit must be less than or equal to the specification.
Interference Checks	List as necessary.

4 Reagent and Standard Solutions

4.1 *Ammonium Molybdate Reagent Solution* — Dissolve 50 g of ammonium molybdate, $(NH_4)_6Mo_7O_{24}$•$4H_2O$, in 1 *N* sulfuric acid and dilute with 1 *N* sulfuric acid to 1000 mL.

4.2 *Ammonium Thiocyanate Reagent Solution* — Dissolve 150 g of ammonium thiocyanate, NH_4SCN, in water and dilute with water to 500 mL.

4.3 *Antimony Standard Solution* — Dissolve and dilute 0.275 g of potassium antimony $KSbO(C_4H_4O_6)$• $1/2H_2O$ with water to 1000 mL (1.0 mL = 0.1 mg of antimony (Sb)).

4.4 *Arsenic Stock and Working Solution* — See Section 3.4.

4.5 *Barium Chloride Solution* — Dissolve 60 g of barium chloride dihydrate, $BaCl_2$•$2H_2O$, in water and dilute with water to 500 mL.

4.6 *Boron Standard Solution* — Dissolve 0.572 g of boric acid, H_3BO_3, in water and dilute to 1000 mL with water. Then dilute 10 mL of this solution with water to 1000 mL (1.0 mL = 0.001 mg of boron (B)).

4.7 *"Bromine Water" Reagent Solution* — Add sufficient liquid bromine to water in a bottle so that undissolved bromine remains as a separate phase when the mixture is shaken.

4.8 *Brucine Sulfate Solution* — Dissolve 0.6 g of brucine sulfate, $(C_{23}H_{26}N_2O_4)_2$•H_2SO_4•$7H_2O$, in dilute sulfuric acid (2 + 1), previously cooled to room temperature, and dilute to 1000 mL with the dilute acid. The sulfuric acid should be nitrate-free acid prepared as follows: Dilute the concentrated sulfuric acid (about 96% H_2SO_4) to about 80% H_2SO_4 by adding it to water, heat to dense fumes of sulfur trioxide, and cool. Repeat the dilution and fuming three or four times.

4.9 *Carminic Acid Reagent Solution* — Dissolve 0.05 g of carminic acid in 100 mL of sulfuric acid and shake until dissolution is complete.

4.10 *Chloride Standard Solution* — Dissolve 0.165 g of sodium chloride, NaCl, in water and dilute with water to 100 mL. Then dilute 10 mL of this solution with water to 1000 mL (1.0 mL = 0.010 mg of chloride (Cl) ion).

4.11 *Dimethylglyoxime Reagent Solution* — Dissolve 1.0 g of dimethylglyoxime in 100 mL of 95% EtOH (ethanol) reagent alcohol.

4.12 *Hydrogen Sulfide Water* — Immediately before use, saturate water with hydrogen sulfide gas.

4.13 *Hydroxylamine Hydrochloride Reagent Solution* — Dissolve 10 g of hydroxylamine hydrochloride, NH_2OH•HCl, in water and dilute with water to 100 mL.

4.14 *Iron Standard Solution* — Dissolve 0.702 g of ferric ammonium sulfate hexahydrate, $Fe(NH_4)_2(-SO_4)_2$ •$6H_2O$, in 10 mL of 10% sulfuric acid and dilute with water to 100 mL. Then to 10 mL of this solution, add 10 mL of 10% sulfuric acid and dilute with water to 1000 mL (1.0 mL = 0.010 mg of iron (Fe) ion).

4.15 *Lead Standard Solution* — Dissolve 0.160 g of lead nitrate, $Pb(NO_3)_2$, in 100 mL of dilute nitric acid (1 + 99) and dilute to 1000 mL with water. Dilute 10 mL of this solution with water to 100 mL immediately before use (1.0 mL = 0.010 mg of lead (Pb) ion).

4.16 *Mercury Standard Solution* — Dissolve 0.677 g of mercuric chloride, $HgCl_2$, in water. Add 8 mL of hydrochloric acid and dilute with water to 500 mL. To 50 mL of this solution add 8 mL of hydrochloric acid and dilute with water to 1000 mL (1.0 mL = 0.05 mg of mercury (Hg) ion).

4.17 *Methyl Orange Indicator Solution* — Dissolve 0.1 g of methyl orange in 100 mL of water.

4.18 *Methyl Red Indicator Solution* — Dissolve 0.1 g of the hydrochloride salt form of methyl red in 100 mL of 95% EtOH (ethnol) reagent alcohol.

4.19 *p-(Methylamino)phenol Sulfate Reagent Solution* — Dissolve 0.2 g of p-(methylamino)phenol sulfate in 100 mL of water and add 20 g of sodium bisulfite. The performance of the resulting reagent solution in the determination of trace phosphate can be verified by the following test:

4.19.1 Place 25 mL of 0.5 *N* sulfuric acid and 1 mL of ammonium molybdate reagent solution in each of four test tubes. Add 1 mL of the reagent solution to each of the tubes. To the tubes add, respectively, zero, 0.005, 0.010, and 0.020 mg of phosphate ion (PO_4). After two hours at room temperature, an increasing intensity of blue color should be visible in the series.

4.20 *Nickel Standard Solution* — Dissolve 0.448 g of nickel sulfate hexahydrate, $NiSO_4$•$6H_2O$, in water and dilute with water to 100 mL. Then dilute 10 mL of this solution with water to 1000 mL (1.0 mL = 0.010 mg of nickel (Ni) ion).

4.21 *Nitrate Standard Solution* — Dissolve 0.163 g of potassium nitrate, KNO_3, in water and dilute with water to 100 mL. Then dilute 10 mL of this solution with water to 1000 mL (1.0 mL = 0.010 mg of nitrate (NO_3) ion).

4.22 *Nitrogen Standard Solution* — Dissolve 0.382 g of ammonium chloride, NH_4Cl, in water and dilute with water to 100 mL. Then dilute 10 mL of this solution with water to 100 mL (1.0 mL = 0.010 mg of nitrogen (N)).

4.23 *Phenolphthalein Indicator Solution* — Dissolve 1 g of phenolphthalein in 100 mL of 95% EtOH (ethanol) reagent alcohol.

4.24 *Phosphate Standard Solution* — Dissolve 0.143 g of monobasic potassium phosphate, KH_2PO_4, in water and dilute to 100 mL with water. Then dilute 10 mL of this solution with water to 1000 mL (1.0 mL = 0.010 mg of phosphate (PO_4) ion).

4.25 *Platinum-Cobalt Stock Solution (APHA 500)* — (See Section 3.2.)

4.26 *Potassium Iodide Reagent Solution* — Dissolve 10 g of potassium iodide, KI, in 100 mL of water. Prepare immediately before use.

4.27 *Potassium Standard Solution* — Dissolve 0.191 g of potassium chloride, KCl, in water and dilute with water to 1000 mL. Dilute 100 mL of this solution with water to 1000 mL (1 mL = 0.010 mg of potassium (K) ion).

4.28 *Silver Nitrate Reagent Solution* — Dissolve 1.7 g of silver nitrate, $AgNO_3$, in water and dilute with water to 100 mL.

4.29 *Sodium Carbonate Reagent Solution* — Dissolve 1.0 g of anhydrous sodium carbonate, Na_2CO_3, in water and dilute with water to 100 mL.

4.30 *Sodium Arsenite Reagent Solution (5%)* — Dissolve 1.0 g of anhydrous sodium arsenite, $NaAsO_2$, in water and dilute with water to 100 mL.

4.31 *Sodium Hydroxide Reagent Solution* — Dissolve 50 g of sodium hydroxide, NaOH, pellets in water and dilute with carbon dioxide-free water to 500 mL.

4.32 *Sodium Standard Solution* — Dissolve 0.254 g of sodium chloride, NaCl, in water and dilute with water to 1000 mL. Then dilute 100 mL of this solution with water to 1000 mL (1 mL = 0.010 mg of sodium (Na) ion).

4.33 *Stannous Chloride Reagent Solution* — Dissolve 20 g of stannous chloride dihydrate, $SnCl_2 \bullet 2H_2O$, in hydrochloric acid and dilute with hydrochloric acid to 100 mL.

4.34 *Starch Indicator Solution* — Mix 1 g of soluble starch for iodometry with 10 mg of red mercuric iodide, HgI_2, and enough cold water to form a thin paste. Add 200 mL of boiling water and boil for 1 minute with stirring. Cool and transfer to a storage bottle that has been well rinsed with hot water.

4.35 *Sulfate Standard Solution* — Dissolve 0.148 g of anhydrous sodium sulfate, Na_2SO_4, in water and dilute with water to 100 mL. Then dilute 10 mL of this solution with water to 1000 mL (1.0 mL = 0.010 mg of sulfate (SO_4) ion).

4.36 *Thymolphthalein Indicator Solution* — Dissolve 0.10 g of thymolphthalein in 100 mL of 95% EtOH (ethanol) reagent alcohol.

5 Safety

5.1 Because of the continuing evolution of safety precautions, it is impossible for this publication to provide definite statements related to the safe handling of individual chemicals. The user is referred to product labels, product data sheets, government regulations, and other relevant literature.

6 Referenced Standards

6.1 *ASTM Standards*[3]

ASTM D5127 — Standard Guide for Ultra Pure Water Used in the Electronics and Semiconductor Industry

SEMI C2-95
SPECIFICATIONS FOR ETCHANTS

1 Preface

1.1 The SEMI Committee on Chemical Reagents began its efforts on etchants in 1979. With this publication, the Committee establishes definitions for three major types of etchant mixtures; mixed acid etchants, buffer oxide etchants, and phosphoric etchants. Specifications and analytical procedures are introduced for each type.

1.2 Etchants within all of the requirements can be described as "meeting SEMI specifications."

1.3 Where an analytical procedure different from that provided is substituted by a supplier or user, the burden of proof is on said supplier or user to confirm the equivalency.

2 Definitions

2.1 All definitions set forth in SEMI C1, Section 2 are adopted for SEMI C2.

2.2 *Etchant* — The exact definition of an etchant mixture shall be set forth as the initial paragraph of its Standard. The composition shall be expressed as a ratio of the relative volumes taken of the components in an assigned order. In the expression, all the relative volumes shall be reduced to a ratio of the smallest whole numbers. If a component is absent, its relative volume shall be taken as zero.

2.3 *Composition* — The content of each component of an etchant shall be expressed on a weight/weight basis of the 100% component (for example, 100% HF, not 49% HF). Any tolerance allowed for the content of a component shall be expressed on a weight/weight basis of that 100% component.

3 General Procedures and Guidelines to Certain Methods

3.1 The general procedures and guidelines for certain methods set forth in SEMI C1, Section 3 are adopted for SEMI C2.

3.2 *Determination of Nitric Acid by Ultraviolet Absorption Spectrophotometry*

3.2.1 *Introduction* — The photometric determination of nitric acid in various etchant mixtures is based on the strong absorption of the nitrate ion in the ultraviolet region. For this spectral region fused silica (quartz) cells are required.

3.2.2 *Preparation of Calibration Curve* — Secure a bottle of nitric acid (70%) and determine its assay in duplicate. Accurately weigh 2.8 to 3.0 g dilute with 100 mL of water, add 10 drops of phenolphthalein indicator solution to each solution, and titrate with standardized 1 *N* sodium hydroxide solution to a pink end-point.

$$\%\text{ Nitric Acid }(w/w) = \frac{\text{mL} \times N \text{ of NaOH} \times 6.302}{\text{Weight of Sample (g)}}$$

If the results do not differ by more than 0.2%, average them. Otherwise, repeat the analysis.

3.2.3 In five previously tared weighing bottles, accurately weigh about 1.0, 1.2, 1.4, 1.6 and 1.8 g of the previously assayed 70% nitric acid. Calculate the weight, in grams, of 100% nitric acid present in each of these five standards. Quantitatively transfer each standard to a separate 100 mL volumetric flask, dilute to volume with water, and mix thoroughly.

3.2.4 Following the manufacturer's directions, ready a spectrophotometer and set the wavelength to 302 nm. Measure the absorbance of each standard versus water using a 1 cm fused silica cell. On (linear) coordinate graph paper plot the absorbance versus the weight, in grams, of 100% nitric acid for each standard. Draw the best-fitting straight line through the points.

3.2.5 *Application to Acid Etch Mixtures* — Proceed as given under the Standard for the relevant etchant.

4 Reagent and Standard Solutions

4.1 The reagent and standard solutions set forth in SEMI C1, Section 4 are adopted for SEMI C2.

4.2 *Acetate Buffer for Hydrofluoric Acid Determination* — Dissolve 106 g of sodium acetate trihydrate, $CH_3COONa{\bullet}3H_2O$, and 137 g of ammonium acetate, CH_3COOHN_4, in about 700 mL of water. Add 5.1 mL of glacial acetic acid, adjust to pH 5.5-6.6 with dilute ammonium hydroxide (10% NH_3) or dilute acetic acid (20%), and dilute to 1000 mL with water.

4.3 *Aluminum Chloride Standard Solution Preparation* — Dissolve 40.0 g of aluminum chloride hexahydrate, $AlCl_3{\bullet}6H_2O$, in about 700 mL of water and 0.5 mL of hydrochloric acid contained in a 1000 mL volumetric flask; dilute to volume with water, and mix thoroughly.

4.3.1 *Standardization* — Transfer 1.5 mL of hydrofluoric acid to a 250 mL polyethylene beaker containing 50 mL of water. Add 10 drops of phenolphthalein indicator solution. With magnetic stirring, titrate with standarized 1*N* sodium hydroxide solution to a pink endpoint. Record the volume of base delivered (A). Add 25 mL of Acetate Buffer for Hydrofluoric Acid Determination and 1 g of Eriochrome Cyanine R indicator mixture; mix thoroughly. With magnetic stirring, titrate with the aluminum chloride solution to a pink-purple endpoint. Record the volume of this solution delivered (B).

$$\text{HF Factor} = \frac{\text{A} \times N \text{ of NaOH} \times 2.001}{\text{B of AlCl}_3 \text{ soln.}}$$

4.4 *Eriochrome Cyanine A Indicator Mixture* — Using a mortar and pestle, thoroughly grind and mix 0.1 g of Eriochrome Cyanine R (C.I. 43820) with 100 g of potassium nitrate.

5 Safety

Because of the continuing evolution of safety precautions, it is impossible in this publication to provide definite statements relating to the safe handling of individual etchants. The user is referred to product labels, product and safety data sheets, government regulations, and other relevant literature.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI C10-0299
GUIDE FOR DETERMINATION OF METHOD DETECTION LIMITS

NOTE: The document that was previously designated as SEMI C10 (Guide for Determination of Method Detection Limits for Trace Metal Analysis by Plasma Spectroscopy) has been redesignated as SEMI C10.1. Because the Guide for Determination of Method Detection Limits is the parent document, it has been designated as SEMI C10.

1. Purpose

1.1 To provide a minimal set of guidelines for the quantitative determination of a method detection limit (MDL) from data supporting a SEMI Process Chemicals or Gases specification.

2. Scope

2.1 This guide applies to trace contaminants specified in SEMI Process Chemicals or Gases standards and guidelines. All relevant trace contaminants should have an MDL determined from a regression analysis of a calibration curve that is equal to, or less than, their specifications. This guide is intended for use in both establishing new specifications within SEMI as well as verification of performance to SEMI specifications.

3. Referenced Documents

3.1 *SEMI Standard*

SEMI C16 — Guide for Precision Reporting/Data Traceability

3.2 *Other Document*[1]

Applied Regression Analysis, 2nd Edition, Norman Draper and Harry Smith, John Wiley and Sons, © 1981

4. Terminology

None.

5. Boundary Conditions

NOTE: A series of boundary conditions is required of the data from which the MDL is to be determined from.

5.1 Data should be collected on at least two standards at different concentration levels, not including the blank.

5.2 The concentration levels investigated must either span the relevant specification or include it as a level. For this purpose, the calibration range can be adjusted for instrument sensitivity by pre-concentration or dilution, if applicable.

5.3 A minimum of three independent sample determinations should be taken on each concentration level of the standard investigated.

5.4 *Matrix Effects*

5.4.1 The blank and the standards should be matrix-matched with the sample when testing a specification and run under the same conditions, both during calibration and sample analysis.

5.4.2 If external standards in a different matrix are used for calibration, the user must compensate for matrix effects using suitable internal standards.

5.5 Where applicable, this guide supersedes the earlier related SEMI Guide: SEMI C16.

5.6 The frequency of the MDL determination should be part of the quality assurance program for the laboratory.

6. Procedure

NOTE: The determination of the MDL should be performed under the same conditions that samples will normally be run. All appropriate precautions to avoid contamination should be followed.

[1] *John Wiley & Sons, Inc., 605 Third Avenue New York, NY 10158-0012, 212.850.6000*

6.1 *Reagents and Standards* — Reagents and standards used should be of the same high-purity as used in the analysis of samples. Accurate standard solutions of trace contaminants are needed for the preparation of the calibration standards. Commercially available standard solutions are suitable. These solutions should be traceable to NIST standards. Working standard solutions should be prepared on the day of use by dilution of the stock standard solution. Standards and blanks should be matrix-matched to the sample to be analyzed.

6.2 *Operating Conditions*

6.2.1 *Instrumental* — Principles of instrumental analysis are provided within many monographs. No general operating conditions are given here since these will vary with the instrument type and design; consequently, the manufacturer's manual should be followed.

6.2.2 *Standard and Sample Preparation* — With certain methods, the achievable MDL can be improved by pre-concentration. Some methods require matrix dilution to run some analyses and may also affect the MDL.

6.2.3 *Calibration* — Calibrate the instrument for all specified trace contaminants using measurement and preparation protocols identical to those used in sample preparation and measurement, wherever appropriate. The calibration data structure used to determine the MDL should be as close to identical as possible to the data structure normally used for calibration in the laboratory. Minimum data requirements should be determinations at, at least, two concentration levels (standards), each independently sampled 3 times. The lowest concentration standard should be at, or below, the specification and give a measurable signal. The blank may be used in the calculation of the MDL if its variability is judged to be representative of that of a very low-level standard. All instrument response data used in the analysis should be measurable. The calibration range can be adjusted for instrument sensitivity by pre-concentration or dilution to match with how the samples are analyzed. Use the data collected to calculate the MDL using the formulas in the next section.

6.3 *Quantification of the MDL*

6.3.1 The MDL is calculated by using the results from a *regression analysis* of the calibration data to obtain a 3 sigma equivalent (in probability) upper confidence limit of individual measurements. Two alternative computational methods are provided for linear calibration models. One provides the MDL based on an ordinary least squares (OLS) regression analysis; the other on a weighted least squares (WLS) based regression analysis. These two computational alternatives **do not** provide the same MDL. The OLS algorithm is appropriate when signal uncertainty remains relatively constant over the window of calibration; otherwise, the WLS algorithm is more appropriate. A third alternative allows the use of similar regression-based approaches for MDL determination in the presence of a more complex calibration model (e.g., nonlinear, multivariate), or when distributional assumptions of the other alternatives are not appropriate. Many software packages perform regression analysis, and their use is recommended.

6.3.2 *Statistical Definitions*

6.3.2.1 *Method detection limit (MDL)* — The level at which the errors in the *measurement method* become large enough such that the preset maximum acceptable risk of seeing the quantified level, when none of the contaminant in question is present in the sample, is exceeded.

6.3.2.2 *risk* — This guide uses 0.13% as the maximum acceptable risk. This is the probability of observing a given result from a normal distribution that is 3 or more standard deviations above the average. Risk is set on a per-contaminant basis.

6.3.2.3 *calibration curve* — An estimate of the relationship between concentration and instrument response (signal intensity). A line, which has not been constrained to pass through the origin, is implicitly assumed in the subsequently provided formulae.

6.3.2.4 *regression analysis* — A curve-fitting technique from which the calibration curve can be estimated.

6.3.2.5 *Ordinary least squares (OLS)* — A curve-fitting criterion which, for a given calibration model, minimizes.

$$\sum_{i=1}^{n}\left(Y_i - \text{Pr}\mathit{edicted}\ Y_i\right)^2$$

Appropriate use of this criterion implicitly assumes that, on average, each determination is made with equal reliability.

6.3.2.6 *Weighted least squares (WLS)* — A curve-fitting criterion which, for a given calibration model, minimizes.

$$\sum_{i=1}^{n} w_i \left(Y_i - \text{Predicted } Y_i\right)^2$$

where, w_i is the weight assigned to the i^{th} data point.

Appropriate use of this criterion implicitly assumes that all w_i are strictly inversely proportional to each point's standard deviation (measure of variation).

6.3.2.7 *t-statistic* — Student's *t* is used instead of the Z-statistic (normal distribution) when the standard deviation is estimated from relatively small quantities of data. It is used herein to explicitly control the risk at 0.13%, regardless of sample size.

- *X's* — The concentrations of the standards used in quantifying the MDL.
- *Y's* — The instrument's response (signal intensity) to each of the *X*'s in question.

6.3.3 *Calculations — OLS and Linear Calibration Model*

6.3.3.1 A line, which is not constrained to pass through the origin, is used as the calibration model. OLS is used to estimate the model. The MDL is located by determining the 3 sigma equivalent Upper Confidence Limit at $X = 0$ and using a linear calibration model to convert this result into the corresponding concentration (MDL).

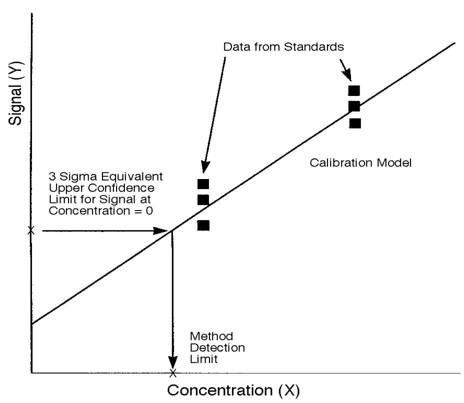

Figure 1
Graphical Visualization of MDL Determination Process

$$MDL = \frac{(UCL - b)}{m}$$

(1) where,

- m = slope determined by OLS analysis (equation 2)
- b = intercept determined by OLS analysis (equation 3)
- UCL = 3 sigma equivalent Upper Confidence Limit at $X = 0$ (equation 4)

$$m = \frac{SS_{xy}}{SS_{xx}}$$

(2), where *SS* stands for Sum of Squares and

$$SS_{xy} = \Sigma_i \left(X_i - \bar{X}\right)\left(Y_i - \bar{Y}\right) = \Sigma_i X_i Y_i - \frac{\left(\Sigma_i X_i\right)\left(\Sigma_i Y_i\right)}{n}$$

where n = total number of observations and i is an index which ranges from 1 to n by 1 in the summations and

$$SS_{xx} = \Sigma_i \left(X_i - \bar{X}\right)^2 = \Sigma_i \left(X_i^2\right) - \frac{\left(\Sigma_i X_i\right)^2}{n}$$

$$b = \bar{Y} - m\bar{X}$$

(3), where

$$\bar{X} = \frac{\Sigma_i X_i}{n}$$

and

$$\bar{Y} = \frac{\Sigma_i Y_i}{n}$$

$$UCL = b + t_{n-2,\ 0.0013}\left(1 + \frac{1}{n} + \frac{(\bar{X})^2}{SS_{xx}}\right)^{1/2} s$$

(4), where

$t_{n-2,\ 0.0013}$ is a t-statistic (from Table 1) with $n-2$ degrees of freedom and 0.0013 as the desired risk of detecting a false positive signal (one-sided, 3 sigma equivalent) and

s = standard deviation of regression model

$$= \left(\frac{\sum_i \left(Y_i - Y_i^*\right)^2}{n-2} \right)^{1/2}$$

where, $Y_i^* = mX_i + b$

Table 1. 3-Sigma Equivalent *t*-Table

n-2	*t*	*n-2*	*t*	*n-2*	*t*
4	6.62	10	3.96	16	3.54
5	5.51	11	3.85	17	3.51
6	4.90	12	3.76	18	3.48
7	4.53	13	3.69	19	3.45
8	4.28	14	3.64	20	3.42
9	4.09	15	3.59		

6.3.3.2 Such analyses should be performed by using a spreadsheet or computer program. It is not recommended to do them by hand. The previous equations neither require nor prevent use of data from blank quantification. In order to use blank data in the MDL quantification with OLS, the blank should be measurable, be likely to give a response which is consistent with the pattern in the other calibration data, and provide a similar level of variability to that obtained from the investigated standards.

6.3.4 *Calculations — WLS and Linear Calibration Model*

6.3.4.1 A line which is not constrained to pass through the origin is used as the calibration model. WLS is used to estimate the model in which the weights are determined as a function of the observed variability at each concentration level. The MDL is located by determining the 3 sigma equivalent Upper Confidence Limit at X = 0 and using a linear calibration model to convert this result into the corresponding concentration (MDL). While the names of many quantities are the same as in the OLS analysis (e.g., $\bar{X}$, $\bar{Y}$, SS_{xx}, and SS_{xy}), the calculations are not.

$$MDL = \frac{(UCL - b)}{m}$$

(5), where

- m = slope determined by WLS analysis (equation 6)
- b = intercept determined by WLS analysis (equation 7)
- UCL = 3 sigma equivalent Upper Confidence Limit at $X = 0$ using WLS (equation 8)

For each of the j levels of concentration, determine the variance of the k determinations (where k can differ for each concentration level, but must be at least 3) as :

$$S_j^2 = \frac{\sum_{l=1}^{k}\left(Y_{j,l} - \bar{Y}_j\right)^2}{(k-1)} \quad \text{where,}$$

$\bar{Y}_j = \dfrac{\sum_{l=1}^{k} Y_{j,l}}{k}$ is used to determine the normalized weight w_j, for any determination at the j^{th} level of concentration as :

$$w_j = \frac{n}{\sum_j \left(\frac{1}{S_j^2}\right)} \frac{1}{S_j^2}, \text{ then}$$

$$m = \frac{SS_{xy}}{SS_{xx}}$$

(6), where

SS stands for Sum of Squares and

$SS_{xy} = \sum_i w_i \left(X_i - \bar{X}\right)\left(Y_i - \bar{Y}\right)$, where n = total number of observations and i is an index which ranges from 1 to n by 1 in the summations and

$$\bar{X} = \frac{\sum_i w_i X_i}{n},$$

$$\bar{Y} = \frac{\sum_i w_i Y_i}{n}, \text{ and}$$

$$SS_{xx} = \sum_i w_i \left(X_i - \bar{X}\right)^2$$

$$b = \bar{Y} - m\bar{X}$$

(7), where

$$UCL = b + t_{n-2,\ 0.0013}\left(\frac{1}{w_0} + \frac{1}{n} + \frac{\left(\bar{X}\right)^2}{SS_{xx}}\right)^{1/2} s$$

(8), where

w_0 is the weight at the intercept (w_0 is either the weight associated with the blank measurements *if they were included in the analysis* or the weight of the lowest concentration standard if the blank measurements are not included in the analysis),

$t_{n-2,\ 0.0013}$ is a t-statistic (from Table 1) with $n-2$ degrees of freedom and 0.0013 as the desired risk of detecting a false positive signal (one-sided, 3 sigma equivalent) and

s = standard deviation of regression model

$$= \left(\frac{SS_{yy} - mSS_{xy}}{n-2}\right)^{1/2} \quad \text{where,}$$

$$SS_{yy} = \sum_i w_i \left(Y_i - \bar{Y}\right)^2$$

6.3.4.2 Since some calculations, for example that of s, may lead to computation of a relatively small difference between two relatively large numbers; it is critical that all previous calculations not be based on rounded numbers. In general, such analyses should be performed using a spreadsheet or computer program.

6.3.4.3 The previous equations neither require nor prevent use of data from blank quantification. In order to use blank data in the MDL quantification with WLS, the blank should be measurable, be likely to give a response which is consistent with the pattern in the other calibration data, and provide a level of variability consistent with the pattern seen in the investigated standards.

6.3.5 *Alternative Calculations* — Situations exist for which both prior alternatives (Sections 6.3.3 and 6.3.4) may be inappropriate. For example:

(a) a calibration model may be nonlinear,

(b) a calibration model may be multivariate in nature,

(c) the implicit assumption of normality of residuals (errors in predictions about the calibration) may not be an appropriate distributional assumption,

(d) the lowest level standard used in calibration may be too far above the true MDL.

6.3.5.1 In case *(a)*, a nonlinear model can be used instead of the default linear model in performing a regression analysis which quantifies the Upper Confidence Limit for individuals at X = 0 at a *3 sigma equivalent probability level* (and back-projects this result through the nonlinear calibration model to estimate the MDL). How to accomplish this is the responsibility of those applying this alternative. In some situations, a transformation of scale (X and/or Y) may linearize the model such that the previously provided calculations are again applicable.

6.3.5.2 In case *(b)*, a multivariate calibration model can be used instead of the default linear model in performing a regression analysis which quantifies the Upper Confidence Limit for individuals at X = 0 at a *3 sigma equivalent probability level* (and back-projects this result through the multivariate calibration model using the observed point of maximum interference in terms of the other concentrations in the range of calibration to estimate the MDL). How to accomplish this is the responsibility of those applying this alternative.

6.3.5.3 In case *(c)*, other error distributions than the normal, can be used wherever appropriate. The same philosophical approach should be applied; a regression analysis which quantifies the Upper Confidence Limit for individuals at X = 0 at a *3 sigma equivalent probability level* (and back-projects this result through the calibration model to estimate the MDL). How to accomplish this is the responsibility of those applying this alternative.

6.3.5.4 In case *(d)*, it is more likely that one will obtain a higher MDL than is truly the case. This phenomena is more likely to occur when the blank is not usable in the regression analysis for any reason. The only fix for this is to reapply the procedure with a set of standards which is not so distant from the MDL, but still otherwise meets the requirements provided herein.

6.3.5.5 In cases *(a)*, *(b)*, and *(c)*, or any combination thereof, the use of appropriate computer/statistical tools is the responsibility of those applying these alternatives. Additional information on regression analysis methods can be found in *Applied Regression Analysis*, 2nd Edition, Norman Draper and Harry Smith, John Wiley and Sons, © 1981.

6.3.6 *Example — Results of Applying (see Sections 6.3.3 and 6.3.4)*

6.3.6.1 Limited result summaries for obtaining the MDL by OLS and WLS are provided for the calibration data in Table 2. These results (Table 3) can be used to benchmark one's implementation of the computational methodology.

Table 2. Calibration Data

Ppb	*signal*	*ppb*	*signal*	*ppb*	*signal*
1	5.03	5	19.87	10	39.90
1	5.00	5	21.20	10	38.28
1	4.91	5	20.45	10	40.93

Table 3. Result Summaries

Statistic	*OLS*	*WLS*
MDL	1.097	0.108
UCL	5.390	1.531
m	3.857	3.869
b	1.157	1.112
s	0.800	0.00997

6.3.6.2 Note the relatively large difference in the estimated MDL (1.10 vs. 0.11) resulting from passing the same data through each of the OLS and WLS algorithms. This data has very different levels of variability, depending on the concentration level of the standard (Table 4). Such data should be analyzed with the WLS rather than the OLS algorithm.

Table 4. Signal Variation by Concentration Level

Concentration Level	*Standard Deviation*	*Variance*
1	0.062	0.0038
5	0.667	0.4449
10	1.336	1.7849

7. Quality Assurance

7.1 Each laboratory that uses this method should do so in accordance with the established quality assurance protocols in place. The MDL, of specified trace contaminants, should be determined whenever a major recalibration of the method and/or instrument is required. The new values should then be used whenever results are reported. A schedule of periodic verification of the MDL, for key trace contaminants, should be incorporated into the program.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI C16-0299
GUIDE FOR PRECISION AND DATA REPORTING PRACTICES

1. Purpose

To provide a minimal set of guidelines for precision and data reporting practices for data supporting a Process Chemicals or Gases SEMI specification.

2. Scope

This guide applies to data collected to support establishment of a SEMI Process Chemicals or Gases specification or verification of performance to such a SEMI specification.

3. Referenced Documents

3.1 *SEMI Standard*

SEMI C1 — Specifications for Reagents

4. Terminology

None.

5. Standards

For each standard used in the study, the following should be reported:

5.1 Preparation method before analysis (e.g., dilution, evaporation).

5.2 Sample matrix.

5.3 Concentration.

5.4 n = number of determinations made on the standard.

5.5 The average of the n determinations.

5.6 The standard deviation of the n measurements (if $n > 1$).

5.7 Range of values observed (if $n > 1$).

5.8 Traceability of the standard.

5.9 If standard was produced internally, how was it produced.

6. Samples

For all reported sample results, including recovery studies, use as many of the reporting requirements for standards as are applicable.

7. Detection Limits

If a detection limit is reported, the specific method or published variant by which the detection limit was obtained, should be named. The level of the lowest standard used in determination of a detection limit should be reported.

8. Internal Standards

For procedures calling for concentration of an analyte by cryogenic trapping, acid extraction, distillation, hydrolization, etc., a recovery study as per Method Validation (Section 3.14 of SEMI C1) is required. For a method to be viable, a recovery in the range of 75 - 125% is recommended.

9. Calibration Models

9.1 The span of the calibration data should include the relevant specification.

9.2 The form of the calibration model (line through origin, line, etc.) should be stated. The assumption of linearity, underlying reliance on two point (zero and span) calibrations for analytical instruments, should be justified by reporting the basis for such an assumption.

9.3 A list of which standards were used to develop the calibration model should be provided.

9.4 Information on which fitting technique was used (i.e., regression using ordinary least squares, weighted least squares, partial least squares) should be provided.

9.5 Identify which, if any, transformations were applied to the calibration data prior to the fitting of the calibration model.

9.6 Identify which response was modeled to establish calibration (i.e., peak area, peak height, response factor).

9.7 A list of the types of standards employed (i.e., internal standards, external standards, method of standard addition) should be provided.

9.8 Report how the calibration data is incorporated in producing the results of an analysis (i.e., zero and span correction, graph).

10. Method Precision

An estimate of method precision should be provided at the level of the specification. Any known interferants or factors which may affect method precision should be stated.

11. Summary

Since only a minimal set of guidelines is provided, those using this guide are encouraged to provide more detail or use more stringent guidelines than those suggested.

SEMI

SEMI C18-0301
SPECIFICATION FOR ACETIC ACID

This specification was technically approved by the Global Process Chemicals Committee and is the direct responsibility of the North American Process Chemicals Committee. Current edition approved by the North American Regional Standards Committee on October 17, 1999. Initially available at www.semi.org February 2001; to be published March 2001. This document replaces SEMI C1.1 in its entirety. Originally published in 1978; previously published June 1999.

1 Purpose

1.1 The purpose of this document is to standardize requirements for acetic acid used in the semiconductor industry and testing procedures to support those standards. Test methods have been shown to give statistically valid results. This document also provides guidelines for grades of acetic acid for which a need has been identified. In the case of the guidelines, the test methods may not have been statistically validated yet.

2 Scope

2.1 The scope of this document is all grades of acetic acid used in the semiconductor industry.

2.2 These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 None.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI C1 — Specifications for Reagents

4.2 *ASTM Standards*[1]

ASTM D5127 — Standard Guide for Ultra Pure Water Used in the Electronics and Semiconductor Industry

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 None.

6 Physical Property (for information only)

Density at 25°C	1.05 g/mL

NOTE 2: This material freezes at about 16°C.

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, Pennsylvania 19428-2959, USA. Telephone: 610.832.9585, Fax: 610.832.9555. Website: www.astm.org

7 Requirements

7.1 The requirements for acetic acid for Grade 1 are listed in Table 1.

8 Grade 1 Procedures

NOTE 3: Each laboratory is responsible for verifying the validity of the method within its own operation.

8.1 *Assay* — Place 15 mL (15.8 g) of sample in a 20 × 150 mm test tube in which is centered an accurate thermometer. The sample tube is centered by one or more stoppers in an outer tube about 38 × 20 mm. Cool the entire apparatus, without stirring, in a bath of shaved or crushed ice and sufficient water to immerse the outer tube above the level of the acetic acid. When the thermometer temperature is about 13°C stir to induce freezing and read the thermometer every half minute. The temperature that remains constant for 1 to 2 minutes is the freezing point and should not be below 16°C, indicating not less than 99.7% as CH_3COOH.

8.2 *Color* — Dilute 2.0 mL of platinum-cobalt stock solution (APHA No. 500) to 100 mL with water. Compare this standard (APHA No. 10) with 100 mL of sample in Nessler tubes. View vertically over a white background. The sample must be no darker than the standard.

8.3 *Residue after Evaporation* — Evaporate 95 mL (100 g) of sample in a tared porcelain or silica dish to dryness on a steam bath in a hood. Dry at 105°C for 30 minutes, cool in a desiccator, and weigh (see SEMI C1, Section 3.3, Determination of Residue After Evaporation).

8.4 *Solubility in Water* — Mix 10 mL of sample with 30 mL of water. Allow to stand 1 hour. The solution should be as clear as an equal volume of water.

8.5 *Chloride* — Dilute 9.5 mL (10 g) of sample with 10 mL of water. Add 1 mL of silver nitrate reagent solution and evaporate to dryness on a steam bath in a hood. Dissolve the residue in 0.5 mL of ammonium hydroxide, dilute with 20 mL of water and add 1.5 mL of nitric acid. Any turbidity produced should be no greater than that produced when 0.01 mg of chloride ion (Cl) is treated as the sample.

8.6 *Phosphate* — Evaporate 9.5 mL (10 g) of sample to dryness on a steam bath in a hood. Dissolve the residue, warming if necessary, in 25 mL of 0.5 N sulfuric acid. Add 1 mL of ammonium molybdate reagent solution and 1 mL of p-(methylamino)phenol sulfate reagent solution. Allow to stand at room temperature for 2 hours. Any blue color should be no greater than that produced when 0.01 mg of phosphate ion (PO_4) is treated as the sample.

8.7 *Substances Reducing Dichromate* — To 10 mL (10.5 g) of sample, add 1.0 mL of 0.1 N (0.017 M) potassium dichromate solution and cautiously add 10 mL of sulfuric acid. Cool the solution to room temperature and allow to stand for 30 minutes. Add 50 mL of water slowly and cautiously with continual swirling, allow to cool, and then add 1 mL of freshly prepared potassium iodide reagent solution. Titrate the liberated iodine with 0.1 N (0.1 M) thiosulfate solution using starch as the indicator. Compare the volume of thiosulfate solution required with that for a 10 mL water blank prepared in parallel with the sample. The difference between the titrations for sample and blank should be no greater than 0.40 mL.

8.8 *Substances Reducing Permanganate* — Dilute 40 mL (42 g) of sample with 10 mL of water. Cool to 15°C, add 0.30 mL of 0.1 N (0.02 M) potassium permanganate, and allow to stand at 15°C for 10 minutes. The pink color should not be entirely discharged.

8.9 *Sulfate* — To 95 mL (100 g) of sample, add 10 mL of sodium carbonate reagent solution and evaporate to dryness in a hood. Dissolve the residue in 10 mL of water and 1 mL of dilute hydrochloric acid (1 + 19); filter if necessary. Add 1 mL of barium chloride reagent solution, mix and allow to stand for 10 minutes. Any turbidity developed should be no greater than that produced when 0.05 mg of sulfate ion (SO_4) is treated as the sample.

8.10 *Arsenic and Antimony (as As)* — To 190 mL (200 g) of sample in a 400 mL beaker, add 5 mL of nitric acid and 5 mL of sulfuric acid and evaporate to dense fumes of sulfur trioxide in a hood. Cool, cautiously add 10 mL of water, and again evaporate to dense fumes of sulfur trioxide. Cool and cautiously wash into a generator flask with water to make a volume of 35 mL. Proceed as described in the General Method for Arsenic (and Antimony) under SEMI C1, Section 3.4.5, starting with the sentence which begins: “Swirl the flask....” Any red color in the silver diethyldithiocarbamate solution of the sample should be no greater than that of the standard containing 0.001 mg of arsenic (As).

8.11 *Acetic Anhydride* — Place 52.2 g (50 mL) of sample in a 250 mL titration flask. In a second flask place 50 mL of glacial acetic acid known to be free from acetic anhydride (see NOTE 3). Into each flask pipet 10 mL of 1.0% solution of 4, 4' -methylenedianiline (4, 4' -diaminodiphenylmethane) in glacial acetic acid (see NOTE 4) and add 0.10 mL of 1.0% solution of crystal violet in glacial acetic acid. Titrate each solution with a 0.1 N solution of perchloric acid in glacial acetic acid (see NOTE 5) to a green endpoint. Subtract the volume for the titration of the sample from the volume for the other titration. One mL of 0.1 N perchloric acid corresponds to 0.0194% $(CH_3CO)_2O$ for a 50 mL sample.

NOTE 4: Glacial acetic acid suspected of containing anhydride may be purified by adding 0.50 mL of water per 100 mL and digesting overnight in a glass-stoppered flask on the steam bath. If this acid is used for comparison in the above test, 0.25 mL of water should be added to the flask containing the test sample just before the endpoint, because water affects the indicator change slightly.

NOTE 5: Dissolve 2.50 g of 4, 4' -methylenedianiline (colorless or only slightly colored) in glacial acetic acid to make 250 mL. Protect the solution from light.

NOTE 6: Slowly add 4.5 mL of 70% perchloric acid to about 400 mL of glacial acetic acid and dilute with glacial acetic acid to 500 mL. Standardize against potassium hydrogen phthalate in glacial acetic acid solution using crystal violet as indicator.

8.12 *Trace Metal Analysis* — The following method has given satisfactory results in determining trace metal impurities at the value specified for each of the following trace metals: aluminum (Al), boron (B), calcium (Ca), chromium (Cr), copper (Cu), gold (Au), iron (Fe), lead (Pb), magnesium (Mg), manganese (Mn), nickel (Ni), potassium (K), sodium (Na), tin (Sn), titanium (Ti), and zinc (Zn). Alternate methods may be used as long as appropriate studies demonstrate recovery between 75 - 125% of a known sample spike for half of the value of each specified item.

8.12.1 *Special Reagents*

8.12.1.1 *Solution A* — Glycerol (ACS Reagent Grade) 10 g, Adipic Acid (99+%) 1 g, EDTA Acid (ACS Reagent Grade) 0.1 g. Dilute to 1 L using water meeting the criteria for Type E1 in ASTM D5127.

8.12.1.2 *Nitric Acid, Ultra Pure* — Use nitric acid specified for ultra low metal ion content.

8.12.1.3 *2% Nitric Acid Solution* — Dilute 10 mL of ultra pure nitric acid to 1 L using water meeting the criteria for Type E1 in ASTM D5127.

8.12.2 *Sample Preparation*

8.12.2.1 In a clean environment, place 100 grams of sample in a PTFE dish. Add 50 mL of solution A. Slowly evaporate on a hot water bath avoiding loss of sample by effervescence or spattering until there is no further loss of liquid. Cool. Add 1 mL of ultra pure, 70% nitric acid. While maintaining volume, carefully warm several minutes to dissolve any residue. Cool. Transfer quantitatively to a 50 mL volumetric flask using 2% nitric acid for rinsing and dilution to volume. Run a reagent blank.

8.12.3 *Analysis*

8.12.3.1 Using the acidic sample standards and a reagent blank, analyze group I elements by flame atomic absorption spectroscopy and all other elements by plasma emission spectroscopy.

Table 1 Impurity Limits and Other Requirements for Acetic Acid

Previous SEMI Reference #	C1.1-96
	Grade 1 (Specification)
Assay (CH_3COOH)	99.7% min
Color (APHA)	10 max
Residue after Evaporation	10 ppm max
Solubility in Water	To pass test
Substances Reducing Dichromate	To pass test
Substances Reducing Permanganate	To pass test
Chloride (Cl)	1 ppm max
Phosphate (PO_4)	1 ppm max
Sulfate (SO_4)	0.5 ppm max
Acetic Anhydride [$(CH_3CO)_2O$]	0.1% max
Aluminum (Al)	0.3 ppm max
Arsenic and Antimony (as As)	0.005 ppm max
Boron (B)	0.2 ppm max
Calcium (Ca)	0.3 ppm max
Chromium (Cr)	0.2 ppm max
Copper (Cu)	0.1 ppm max
Gold (Au)	0.3 ppm max
Iron (Fe)	0.2 ppm max
Lead (Pb)	0.3 ppm max
Magnesium (Mg)	0.3 ppm max
Manganese (Mn)	0.3 ppm max
Nickel (Ni)	0.1 ppm max
Potassium (K)	0.3 ppm max

Previous SEMI Reference #	C1.1-96
	Grade 1 (Specification)
Sodium (Na)	0.3 ppm max
Tin (Sn)	0.3 ppm max
Titanium (Ti)	0.3 ppm max
Zinc (Zn)	0.3 ppm max
Particles in bottles: size, #/mL	≥1.0 µm, 25 max

SEMI C19-0301
SPECIFICATION FOR ACETONE

This specification was technically approved by the Global Process Chemicals Committee and is the direct responsibility of the North American Process Chemicals Committee. Current edition approved by the North American Regional Standards Committee on October 17, 1999. Initially available at www.semi.org February 2001; to be published March 2001. This document replaces SEMI C1.2 in its entirety. Originally published in 1978; previously published June 1999.

1 Purpose

1.1 The purpose of this document is to standardize requirements for acetone used in the semiconductor industry and testing procedures to support those standards. Test methods have been shown to give statistically valid results. This document also provides guidelines for grades of acetone for which a need has been identified. In the case of the guidelines, the test methods may not have been statistically validated yet.

2 Scope

2.1 The scope of this document is all grades of acetone used in the semiconductor industry.

2.2 These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 None.

4 Referenced Documents

SEMI C1 — Specifications for Reagents

4.2 *ASTM Standards*[1]

ASTM D5127 — Standard Guide for Ultra Pure Water Used in the Electronics and Semiconductor Industry

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 None.

6 Physical Property (for information only)

Density at 25°C	0.79 g/mL
Boiling Point	56.3°C

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, Pennsylvania 19428-2959, USA. Telephone: 610.832.9585, Fax: 610.832.9555. Website: www.astm.org

7 Requirements

7.1 The requirements for acetone for Grade 1 are listed in Table 1.

8 Grade 1 Procedures

NOTE 2: Each laboratory is responsible for verifying the validity of the method within its own operation.

8.1 *Assay* — Analyze the sample by gas chromatography (see SEMI C1, Section 3.1, Guidelines for Assay by Wide Bore Column Gas Chromatography). The parameters cited have given satisfactory results.

Column: 30 meter × 530 micron I.D.-fused silica capillary, coated with 1 mm film of DB-1701 or equivalent (14% cyanopropyphenyl which has been surface bonded and crosslinked).

Column Temperature: 40°C isothermal for 5 minutes, then programmed to 200°C at 10°C/min.

Injector Temperature:	150°C
Detector Temperature:	250°C
Sample Size:	1 µL split
Carrier Gas:	Helium at 3 mL/min
Detector:	Flame Ionization
Approximate Retention Times (min):	
Methanol	1.1
Acetaldehyde	2.3
Acetone	2.9
Isopropanol	3.3
Cumene	10.0
Mesityl Oxide	11.8
Diacetone Alcohol	12.0

8.2 *Color* — Dilute 2.0 mL of platinum-cobalt stock solution (APHA No. 500) to 100 mL with water. Compare this standard (APHA No. 10) with 100 mL of sample in Nessler tubes. View vertically over white background. The sample must be no darker than the standard.

8.3 *Acidity* — To 25 mL of water in a glass-stoppered flask, add 10 mL of sample and 0.1 mL of phenolphthalein indicator solution. Add 0.01 N sodium hydroxide until a slight, pink color persists after shaking for one-half minute. Add 42 mL (33 g) of the sample, mix well, and titrate with 0.01 N sodium hydroxide until the pink color is reproduced. Not more than 1.0 mL of the sodium hydroxide solution should be required.

8.4 *Alkalinity* — Add 25 mL (20 g) of sample to 25 mL of water and mix well. Add 0.05 mL of methyl red indicator solution. Titrate with 0.01 N hydrochloric acid until a slight pink color is produced. Not more than 1.0 mL of the hydrochloric acid should be required.

8.5 *Residue after Evaporation* — Evaporate 253 mL (200 g) of sample to dryness. Dry at 105°C for 30 minutes, cool in a desiccator, and weigh (see SEMI C1, Section 3.3, Determination of Residue After Evaporation).

8.6 *Water* — Add 25 mL of pyridine to a dry titration flask and add Karl Fischer (KF) reagent to a visually or electrometrically determined endpoint that persists for 30 seconds. Add 25 mL (20 g) of sample, taking care to protect the sample and contents of the flask from moisture. Stir vigorously and titrate with Karl Fischer reagent to the same endpoint.

$$\%\ \text{Water}\ (H_2O) = \frac{\text{mL KF reagent} \times \text{KF factor}\ (\text{g}\ H_2O/\text{mL}) \times 100}{\text{Weight of sample}\ (\text{g})}$$

8.7 *Solubility in Water* — Mix 40 mL of sample with 40 mL of water. Allow to stand for 30 minutes. The solution should be as clear as an equal volume of water.

8.8 *Chloride* — To 63 mL (50 g) of sample, add 10 mL of sodium carbonate reagent solution and evaporate to dryness on a steam bath in a hood. Dissolve the residue in 10 mL of water. Add 1 mL of nitric acid, dilute to 20 mL with water, and add 1 mL of silver nitrate reagent solution. Any turbidity produced should be no greater than that produced when 0.01 mg of chloride ion (Cl) is treated as the sample.

8.9 *Phosphate* — To 125 mL (100 g) of sample, add 10 mL of sodium carbonate reagent solution and evaporate to dryness on a steam bath in a hood. Dissolve the residue in 25 mL of 0.5 N sulfuric acid. Add 1 mL of ammonium molybdate reagent solution and 1 mL of p-(methylamino)phenol sulfate reagent solution. Allow to stand at room temperature for 2 hours. Any blue color produced should be no greater than that produced when 0.01 mg of phosphate ion (PO_4) is treated as the sample.

8.10 *Arsenic and Antimony (as As)* — Evaporate 250 mL (200 g) of sample in a 400 mL beaker to a small volume in a hood. Add 50 mL of water and again evaporate to a small volume. Repeat the evaporation with water addition. Do not allow to go to dryness. Add 5 mL of nitric acid, 5 mL of sulfuric acid and evaporate to dense fumes of sulfur trioxide. Cool, cautiously add 10 mL of water, and again evaporate to dense fumes of sulfur trioxide. Cool, and cautiously wash into a generator flask with water to make a volume of 35 mL. Proceed as described in the General Method for Arsenic (and Antimony) under SEMI C1, Section 3.4.5, starting with the sentence which begins: "Swirl the flask...." Any red color in the silver diethyldithiocarbamate solution of the sample should be no greater than that of the standard containing 0.002 mg of arsenic (As).

8.11 *Trace Metal Analysis* — The following method has given satisfactory results in determining trace metal impurities at the value specified for each of the following trace metals: aluminum (Al), boron (B), calcium (Ca), chromium (Cr), copper (Cu), gold (Au), iron (Fe), lead (Pb), magnesium (Mg), manganese (Mn), nickel (Ni), potassium (K), sodium (Na), tin (Sn), titanium (Ti), and zinc (Zn). Alternate methods may be used as long as appropriate studies demonstrate recovery between 75 - 125% of a known sample spike for half of the value of each specified item.

8.11.1 *Special Reagents*

8.11.1.1 *Hydrochloric Acid, Ultra Pure* — Use hydrochloric acid specified for ultra low metal ion content.

8.11.1.2 *Mannitol Powder* — Use mannitol specified for reagent grade (A.C.S.) and determined, via the reagent blank, to be ultra low metal ion content.

8.11.1.3 *5% Mannitol Solution* — Dissolve and dilute 5 g of mannitol to 100 mL using water meeting the criteria for Type E1 in ASTM D5127.

8.11.1.4 *2% (v/v) Hydrochloric Acid Solution* — Dilute 20 mL of ultra pure, 12 M hydrochloric acid to 1 L using water meeting the criteria for Type E1 in ASTM D5127.

8.11.2 *Sample Preparation*

8.11.2.1 In a clean environment, place 250 g of solvent in a PTFE dish. Add 0.5 mL of freshly prepared 5% mannitol solution. Slowly evaporate on a hot plate avoiding loss of sample by effervescence or spattering until approximately 1 mL of liquid remains. Take up liquid and all visible residue (from walls of dish) with 1 mL ultra pure, 12 M hydrochloric acid and continue heating until approximately 0.5 mL of liquid remains. No undissolved particulate matter should be observed. Otherwise repeat the addition of hydrochloric acid until all particulate matter is dissolved. Transfer quantitatively to a 50 mL volumetric flask using 2% (v/v) hydrochloric acid and adjust liquid level to mark. Prepare a reagent blank using the same reagents and in the same manner as for the sample concentration.

8.11.3 *Analysis*

8.11.3.1 Using the prepared sample and reagent blank, analyze group I elements potassium (K) and sodium (Na) by atomic absorption spectroscopy and all other elements by plasma emission spectrometry. Apply, if necessary, a reagent blank correction to the final determined value of the sample.

NOTE 3: Due to the uncertainty of acid concentration in the liquid residue the final concentration can be estimated to be approximately 2% (v/v).

SEMI C20-1101
SPECIFICATION AND GUIDELINES FOR AMMONIUM FLUORIDE 40%

This specification and these guidelines were technically approved by the Global Process Chemicals Committee and are the direct responsibility of the North American Process Chemicals Committee. Current edition approved by the North American Regional Standards Committee on August 27, 2001. Initially available at www.semi.org September 2001; to be published November 2001. This document replaces SEMI C1.3, C7.18, and C11.2 in their entirety. Originally published in 1978, 1995, and 1994 respectively. Previously published March 2001.

1 Purpose

1.1 The purpose of this document is to standardize requirements for ammonium fluoride 40% used in the semiconductor industry and testing procedures to support those standards. Test methods have been shown to give statistically valid results. This document also provides guidelines for grades of ammonium fluoride 40% for which a need has been identified. In the case of the guidelines, the test methods may not have been statistically validated yet.

2 Scope

2.1 The scope of this document is all grades of ammonium fluoride 40% used in the semiconductor industry.

2.2 The VLSI grade purity level is typically required by semiconductor devices with geometries of 0.8–1.2 microns.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 None.

4 Referenced Standards

SEMI C1 — Specifications for Reagents

NOTE 1: Unless otherwise indicated, all documents cited shall be the latest published versions.

5 Terminology

5.1 None.

6 Physical Property (for information only)

Density at 25°C	1.11 g/mL

7 Requirements

7.1 The requirements for ammonium fluoride 40% for Grade 1, VLSI Grade, and Tiers A and B are listed in Table 1.

8 Grade 1 Procedures

8.1 *Assay* — Accurately weigh 3 g of sample in a polyethylene weighing bottle. Transfer with water to a polyethylene beaker and dilute to 100 mL. Add 40 mL of neutralized formaldehyde solution and stir magnetically for 15 minutes or allow to stand for 1/2 hour. Titrate with standardized 1 N sodium hydroxide to a slight pink color.

$$\%\text{Assay} = \frac{\text{mL} \times \text{N of NaOH} \times 3.704}{\text{Weight of sample (g)}}$$

NOTE 2: *Neutralized formaldehyde solution:* Dilute 20 mL of 37% formaldehyde solution with 20 mL of water, add 0.1 mL of phenolphthalein indicator solution, and titrate with 0.1 N sodium hydroxide to a slight pink color.

8.2 *Color* — Dilute 2.0 mL of platinum-cobalt stock solution (APHA No. 500) to 100 mL with water. Compare this standard (APHA No. 10) with 100 mL of sample in Nessler tubes. View vertically over a white background. The sample must be no darker than the standard.

8.3 *pH of a 1% solution* — Dilute 2.5 mL (2.8 g) of sample to 100 mL with carbon dioxide- and ammonia-free water. Using a pH meter determine the pH at 25°C 1 to 2 minutes after immersion of electrodes. The pH range 6.0–7.5 corresponds to 0.2% free hydrogen fluoride (HF) to 0.2% ammonium hydroxide (NH_4OH) in the original solution.

8.4 *Chloride* — Mix 2.2 mL (2.5 g) of sample with 20 mL of water containing 0.5 g of boric acid. Add 1 mL of nitric acid and 1 mL of silver nitrate reagent solution, and allow to stand for 5 minutes. Any turbidity produced should be no greater than that produced when 0.01 mg of chloride ion (Cl) is treated as the sample.

8.5 *Nitrate* — To 2 mL of water in a white plastic beaker, add 0.9 mL (1 g) of sample, 1 mL of sulfuric acid, 0.05 mL of 0.01 N (0.002 M) potassium permanganate, mix, and decolorize with sodium arsenite reagent solution. Dilute to 50 mL with brucine sulfate reagent solution and mix. Heat the solution in a preheated (boiling water) bath for 10 minutes. Cool rapidly in an ice bath to room temperature. The yellow color of the sample should be no greater than that produced when 0.01 mg of nitrate ion (NO_3) is treated as the sample.

8.6 *Phosphate* — To a 9 mL (10 g) sample in a platinum dish, add 1 mL of sodium carbonate reagent solution and 40 mL of nitric acid. Evaporate carefully, to prevent spattering, to near dryness. Cool, wash down the sides of the dish with 5 mL of nitric acid, and evaporate to dryness. Repeat the evaporation with nitric acid two more times to ensure complete removal of all the fluoride. To the cooled dish, add 25 mL of 0.5 N sulfuric acid to dissolve the residue, warming if necessary. Cool, transfer to a color comparison tube, and add 1 mL of ammonium molybdate reagent solution, 1 mL of p-(methylamino)phenol sulfate reagent solution, and allow to stand at room temperature for 2 hours. Any blue color should be no greater than that produced when 0.01 mg of phosphate ion (PO_4) is treated as the sample.

8.7 *Sulfate* — To 23 mL (25 g) of sample, add 10 mL of sodium carbonate reagent solution and heat gently until sample has been volatilized. To the residue add 5 mL of hydrochloric acid and evaporate to dryness in a hood. Dissolve the residue in 10 mL of water and 1 mL of dilute hydrochloric acid (1 + 19); filter if necessary. Add 1 mL of barium chloride reagent solution, mix, and allow to stand for 10 minutes. Any turbidity developed should be no greater than that produced when 0.05 mg of sulfate ion (SO_4) solution is treated as the sample.

8.8 *Arsenic and Antimony (as As)* — To 30 mL (33 g) in a fluoroplastic beaker, add 20 mL of nitric acid and 5 mL of hydrochloric acid, and evaporate to dryness in a sand bath in a hood. Completely volatilize the ammonium fluoride, but do not bake. Add 10 mL of water and 5 mL of sulfuric acid and evaporate to dense fumes of sulfur trioxide. Cool, cautiously add 10 mL of water, and again evaporate to dense fumes of sulfur trioxide. Cool, and cautiously wash into a generator flask with water to make a volume of 35 mL. Proceed as described in the General Method for Arsenic (and Antimony) under SEMI C1, Section 3.4.5, starting with the sentence that begins, "Swirl the flask...." Any red color in the silver diethyldithiocarbamate solution of the sample should be no greater than that of the standard containing 0.001 mg of arsenic (As).

8.9 *Trace Element Contents* — By a suitable emission spectrographic procedure, determine for each of the specified trace elements that its content is not greater than the stated specification limit (see SEMI C1, Section 3.5, Guidelines for Emission Spectrography).

9 Grade 2 Procedures

9.1 This section does not apply to this chemical.

10 Grade 3 Procedures

10.1 This section does not apply to this chemical.

11 Grade 4 Procedures

11.1 This section does not apply to this chemical.

12 Grade 5 Procedures

12.1 This section does not apply to this chemical.

13 VLSI Grade Procedures

13.1 Specific procedures for this grade do not exist. Refer to Section 8 for available procedures.

14 Tier A Procedures

14.1 Standardized test methods are being developed for all parameters at the purity levels indicated. The Process Chemicals Committee considers a test method to be valid only if there is a documented recovery study showing a recovery of 75–125%. Recovery is for a known sample spike at 50% of the specified level.

15 Tier B Procedures

15.1 Standardized test methods are being developed for all parameters at the purity levels indicated. The Process Chemicals Committee considers a test method to be valid if there is a documented recovery study showing a recovery of 75–125%. Recovery is for a known sample spike at 50% of the specified level.

16 Tier C Procedures

16.1 This section does not apply to this chemical.

17 Tier D Procedures

17.1 This section does not apply to this chemical.

Table 1 Impurity Limits and Other Requirements for Ammonium Fluoride 40%

Particles in bottles: size, #/mL	≥ 1.0 µm, 25 max	≥ 0.5 µm, 250 max	See NOTE 2.	See NOTE 2.

NOTE 1: For III-V compound users only.

NOTE 2: Due to the limitations of current particle counters, particle size and number are to be agreed upon between supplier and user. See SEMI C1, Section 3.9 for particle counting methodology.

NOTICE: SEMI makes no warranties or representations as to the suitability of the standard set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials or equipment mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI C21-0301
SPECIFICATIONS AND GUIDELINES FOR AMMONIUM HYDROXIDE

These specifications and guidelines were technically approved by the Global Process Chemicals Committee and are the direct responsibility of the North American Process Chemicals Committee. Current edition approved by the North American Regional Standards Committee on October 17, 1999. Initially available on SEMI OnLine February 2001; to be published March 2001. This document replaces SEMI C1.4, C7.1, C8.1, C11.1, and C17.1 in their entirety. Originally published in 1978, 1990, 1992, 1994, and 1997 respectively; previously published June 2000.

1 Purpose

1.1 The purpose of this document is to standardize requirements for ammonium hydroxide used in the semiconductor industry and testing procedures to support those standards. Test methods have been shown to give statistically valid results. This document also provides guidelines for grades of ammonium hydroxide for which a need has been identified. In the case of the guidelines, the test methods may not have been statistically validated yet.

2 Scope

2.1 The scope of this document is all grades of ammonium hydroxide used in the semiconductor industry.

2.2 The VLSI grade purity level is typically required by semiconductor devices with geometries of 0.8–1.2 microns.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 The guideline for VLSI grade ammonium hydroxide is only applicable for materials that remain below 25°C during transport and storage.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI C1 — Specifications for Reagents

4.2 *ASTM Standards*[1]

ASTM D5127 — Standard Guide for Ultra Pure Water Used in the Electronics and Semiconductor Industry

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 None.

6 Physical Property (for information only)

Density at 25°C	0.90 g/mL

7 Requirements

7.1 The requirements for ammonium hydroxide for Grades 1, 2, 3, and 4, and VLSI Grade are listed in Table 1.

8 Grade 1 Procedures

NOTE 2: Each laboratory is responsible for verifying the validity of the method within its own operation.

8.1 *Assay* — Accurately weigh a small glass-stoppered flask containing about 15 mL of water. Deliver from a pipet about 2 mL of the sample near the water surface, stopper immediately, and reweigh. Add 0.1 mL of methyl red indicator solution and titrate with standardized 1 N hydrochloric acid to a yellow-to-red color change.

$$\%\text{Assay} = \frac{\text{mL} \times \text{N of HCl} \times 1.703}{\text{Weight of sample (g)}}$$

8.2 *Appearance* — Place 15 mL of the sample in a 20 × 150 mm test tube and compare with water in a similar tube. Viewed across the column by means of transmitted light, the two liquids should be equal in clarity and free from suspended matter.

8.3 *Color* — Dilute 2.0 mL of platinum-cobalt stock solution (APHA No. 500) to 100 mL with water. Compare this standard (APHA No. 10) with 100 mL of sample in Nessler tubes. View vertically over a white background. The sample must be no darker than the standard.

8.4 *Carbon Dioxide* — Dilute 11 mL (10 g) of sample with 10 mL of carbon dioxide-free water and add 5 mL of a clear, saturated solution of barium hydroxide. Any turbidity should be no greater than that produced when

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, Pennsylvania 19428-2959, USA. Telephone: 610.832.9585, Fax: 610.832.9555. Website: www.astm.org

the same volume of the barium hydroxide solution is added to 21 mL of the carbon dioxide-free water containing 0.5 mg of anhydrous sodium carbonate.

8.5 *Substances Reducing Permanganate* — Dilute 3 mL (2.7 g) of sample with 5 mL of water. Add 50 mL of 10% sulfuric acid and 0.05 mL of 0.1 N (0.02 M) potassium permanganate. Boil for 5 minutes. The pink color should not be entirely discharged.

8.6 *Chloride* — To 22 mL (20 g) of sample, add 10 mL of sodium carbonate reagent solution and evaporate to dryness on a steam bath in a hood. Dissolve the residue in 10 mL of water. Add 1 mL of nitric acid. Filter, if necessary, through a chloride-free filter. Dilute to 20 mL with water and add 1 mL of silver nitrate reagent solution. Any turbidity produced should be no greater than that produced when 0.01 mg of chloride ion (Cl) is treated as the sample.

8.7 *Phosphate* — Evaporate 22 mL (20 g) of sample to dryness on a steam bath in a hood. Take up the residue with 25 mL of approximately 0.5 N sulfuric acid. Add 1 mL of ammonium molybdate reagent solution and 1 mL of p-(methylamino)phenol sulfate reagent solution, and allow to stand for 2 hours at room temperature. Any blue color should be no greater than that produced when 0.01 mg of phosphate ion (PO_4) is treated as the sample.

8.8 *Total Sulfur (as SO_4)* — To 56 mL (50 g) of sample, add 1 mL of sodium carbonate reagent solution and evaporate on a steam bath in a hood to a volume of about 5 mL. Add 2 mL of bromine water and evaporate to dryness. Dissolve the residue with 10 mL of water and 1 mL of dilute hydrochloric acid (1 + 19); filter, if necessary. Add 1 mL of barium chloride reagent solution, mix, and allow to stand for 10 minutes. Any turbidity developed should be no greater than that produced when 0.05 mg of sulfate ion (SO_4) is treated as the sample.

8.9 *Arsenic and Antimony (as As)* — Evaporate 44 mL (40 g) of sample in a 150 mL beaker to a small volume in a hood. Cool, cautiously add 10 mL of water and 5 mL of sulfuric acid, and wash into a generator flask with water to make a volume of 35 mL. Proceed as described in the General Method for Arsenic (and Antimony) under SEMI C1, Section, 3.4.5, starting with the sentence that begins, "Swirl the flask...." Any red color in the silver diethyldithiocarbamate solution of the sample should be no greater than that of the standard containing 0.002 mg of arsenic (As).

8.10 *Trace Metal Analysis* — The following method has given satisfactory results in determining trace metal impurities at the value specified for each of the following trace metal impurities at the value specified for each of the following trace metals: aluminum (Al), boron (B), calcium (Ca), chromium (Cr), copper (Cu), gold (Au), iron (Fe), lead (Pb), magnesium (Mg), manganese (Mn), nickel (Ni), potassium (K), sodium (Na), tin (Sn), titanium (Ti), and zinc (Zn). Alternate methods may be used as long as appropriate studies demonstrate recovery between 75 - 125% of a known sample spike for half of the value of each specified item.

8.10.1 *Special Reagents*

8.10.1.1 *5% Mannitol Solution* — Weigh out 5 g of Mannitol Powder (ACS Reagents Grade), and dilute to 100 mL using water meeting the criteria for Type E1 in ASTM D5127. Mannitol solution is subject to attack by microorganisms and should be carefully monitored for such contamination.

8.10.1.2 *Hydrochloric Acid, Ultra Pure* — Use hydrochloric acid specified for ultra low metal ion content.

8.10.1.3 *2% (v/v) Hydrochloric Acid Solution* — Dilute 20 mL of ultra pure hydrochloric acid to 1 L using water meeting the criteria for Type E1 in ASTM D5127.

8.10.2 *Sample Preparation*

8.10.2.1 In a clean environment, place 250 mL of aqueous ammonium hydroxide in a PTFE dish. Add 0.5 mL of freshly prepared 5% mannitol solution. Slowly evaporate on a hot plate, avoiding loss of sample by effervescence or spattering until approximately 1 mL of liquid remains. Cool. Add 1 mL of ultra pure, 12 M hydrochloric acid. Continue heating until approximately 0.5 mL of liquid remains. Cool. Transfer quantitatively to 50 mL volumetric flask using 2% (v/v) hydrochloric acid for rinsing and dilution to volume. Run reagent blank.

8.10.3 *Analysis*

8.10.3.1 Using the acid sample and reagent blank, analyze group 1 elements by flame atomic absorption spectroscopy and all other elements by plasma emission spectroscopy.

NOTE 3: Due to the uncertainty of the acid concetration in the liquid residue, the final concentration can be estimated at approximately 1-2% (v/v). Standard calibration solutions are to use this same acid concentration.

9 Grade 2 Procedures

NOTE 4: Each laboratory is responsible for verifying the validity of the method within its own operation.

9.1 *Non-Metal Impurities*

9.1.1 See Section 8, which contains procedures for the following tests:

Assay

Color (APHA)

Carbon Dioxide

Substances Reducing Permanganate

9.2 *Anions*

9.2.1 The following method has given satisfactory results in determining anion impurities at the values specified for each of the following anions: chloride (Cl), phosphate (PO_4), nitrate (NO_3), and sulfate (SO_4). Alternate methods may be used as long as appropriate studies demonstrate a recovery between 75–125% of a known sample spike for half of the value of each specified anion.

9.2.2 *Special Reagents*

9.2.2.1 *Eluent* — Prepare an eluent solution that is 2.2 mM sodium carbonate (Na_2CO_3) and 0.75 mM sodium bicarbonate ($NaHCO_3$) in deionized water meeting the criteria for Type E1.1 in ASTM D5127. Store eluent under a helium gas blanket.

9.2.2.2 *Regenerant* — Prepare a 0.025 N sulfuric acid (H_2SO_4) in deionized water meeting the criteria for Type E1.1 in ASTM D5127.

9.2.2.3 *Potassium Carbonate Solution* — Prepare a solution containing 500 mg of reagent grade potassium carbonate (K_2CO_3) into 100 mL of water meeting the criteria for Type E1.1 in ASTM D5127.

9.2.3 *Sample Preparation*

9.2.3.1 In a clean environment, place 40 g of sample into a clean beaker. Add 1 mL of a 5 mg/mL potassium carbonate solution and evaporate carefully (at 100°C) to a volume of 0.5 mL. Dilute with water meeting the criteria for Type E1.1 in ASTM D5127 to a final volume of 20 mL.

9.2.4 *Analysis*

9.2.4.1 Using the prepared solutions and blanks, analyze chloride, nitrate, phosphate, and sulfate by ion chromatography. Run a reagent blank. Samples and reagent blanks should be prepared and analyzed in triplicate.

9.2.4.2 *Columns* — Precolumn should be AG4-A (Dionex) or equivalent and Separation column should be AS4-A (Dionex) or equivalent.

9.3 *Trace Metals Analysis*

9.3.1 The following method has given satisfactory results in determining metal ion impurities at the values specified for each of the following metals: aluminum (Al), antimony (Sb), arsenic (As), boron (B), calcium (Ca), chromium (Cr), copper (Cu), gold (Au), iron (Fe), lead (Pb), magnesium (Mg), manganese (Mn), nickel (Ni), potassium (K), sodium (Na), titanium (Ti), and zinc (Zn). Alternate methods may be used as long as appropriate studies demonstrate a recovery between 75 - 125% of a known sample spike for half of the value of each specified element.

9.3.2 *Special Reagents*

9.3.2.1 *Nitric Acid, Ultra Pure* — Use nitric acid specified for low metal ion content.

9.3.2.2 *4% Nitric Acid Solution* — Dilute 40 mL of ultra pure nitric acid to 1 L using water meeting the criteria for Type E1.1 in ASTM D5127.

9.3.2.3 *Water* — The water used for all the dilution, calibration, and standards should meet at a minimum the criteria for Type E1.1 in ASTM D5127 in regard to cation analysis.

9.3.2.4 *Indium Internal Standard* — Make up an indium internal standard solution to a concentration of 20 µg/mL (ppm) from an appropriate concentrated indium standard solution.

9.3.3 *Sample Preparation*

9.3.3.1 In a clean environment, evaporate a 50.0 g sample at low heat until approximately 20 g of the sample remains. Carefully add 1 mL of the ultra pure nitric acid and gently warm for several minutes. Cool to room temperature, add 25 µL of the indium internal standard, and dilute with Type E1.1 water to a final weight of 25.0 g.

9.3.4 *Analysis*

9.3.4.1 Using the prepared solutions and blanks, analyze sodium, potassium, calcium, and iron by graphite furnace atomic absorption (GFAA) and the remaining elements by inductively coupled plasma mass spectrometry (ICP/MS). For calibration, the standards are made up in 4% nitric acid solution with final concentration of 20 ng/g of the indium internal standard. Run a reagent blank.

10 Grade 3 Procedures

NOTE 5: The analytical procedures associated with this standard are not intended to be the only acceptable procedure or the best procedure available. The published procedures have been found to meet the required criteria for acceptance of an analytical procedure. Alternate procedures may be used if they meet the same criteria as the published procedures.

NOTE 6: Each laboratory is responsible for verifying the validity of each method within its own operation.

10.1 *Non-Metal Impurities*

10.1.1 See Section 8, which contains procedures for the following tests:

Assay

Color (APHA)

Carbon Dioxide

Substances Reducing Permanganate

10.2 *Anions*

10.2.1 The following method has given satisfactory results in determining anion impurities at the values specified for each of the following anions: chloride (Cl), phosphate (PO_4), and sulfate (SO_4). Alternate methods may be used as long as appropriate studies demonstrate a recovery between 75–125% of a known sample spike for half of the value of each specified element.

10.2.2 *Special Reagents*

10.2.2.1 *Eluent* — Prepare an eluent solution that is 2.2 mM sodium carbonate (Na_2CO_3) and 0.75 mM sodium bicarbonate ($NaHCO_3$) in deionized water meeting the criteria for Type E1.1 in ASTM D5127. Store eluent under a helium gas blanket.

10.2.2.2 *Regenerant* — Prepare a 0.025 N sulfuric acid (H_2SO_4) in deionized water meeting the criteria for Type E1.1 in ASTM D5127.

10.2.2.3 *Potassium Carbonate Solution* — Prepare a solution containing 500 mg of reagent grade potassium carbonate (K_2CO_3) in 100 mL of water meeting the criteria for Type E1.1 in ASTM D5127.

10.2.3 *Sample Preparation*

10.2.3.1 In a clean environment, place 40 g of sample into a clean beaker. Add 1 mL of a 5 mg/mL potassium carbonate solution and evaporate carefully (at 100°C) to a volume of 0.5 mL. Dilute with water meeting the criteria for Type E1.1 in ASTM D5127 to a final volume of 20 mL.

10.2.4 *Analysis*

10.2.4.1 Using the prepared solutions and blanks, analyze chloride, nitrate, phosphate, and sulfate by ion chromatography. Run a reagent blank. Samples and reagent blanks should be prepared and analyzed in triplicate.

10.2.4.2 *Columns* — Precolumn should be AG4-A (Dionex) or equivalent, and separation column should be AS4-A (Dionex) or equivalent.

10.3 *Trace Metals Analysis*

10.3.1 The following method has given satisfactory results in determining metal ion impurities at the values specified for each of the following metals: aluminum (Al), antimony (Sb), arsenic (As), boron (B), calcium (Ca), chromium (Cr), copper (Cu), gold (Au), iron (Fe), lead (Pb), magnesium (Mg), manganese (Mn), nickel (Ni), potassium (K), sodium (Na), tin (Sn), titanium (Ti), and zinc (Zn). Alternate methods may be used as long as appropriate studies demonstrate a recovery between 75–125% of a known sample spike for half of the value of each specified element.

10.3.2 *Special Reagents*

10.3.2.1 *Nitric Acid, Ultra Pure* — Use nitric acid specified for low metal ion content.

10.3.2.2 *4% Nitric Acid Solution* — Dilute 40 mL of ultra pure nitric acid to 1 L using water meeting the criteria for Type E1.1 in ASTM D5127.

10.3.2.3 *Water* — The water used for all the dilution, calibration, and standards should meet, at a minimum, the criteria for Type E1.1 in ASTM D5127 in regard to cation analysis.

10.3.2.4 *Indium Internal Standard* — Make up an indium internal standard solution to a concentration of 20 µg/mL (ppm) from an appropriate concentrated indium standard solution.

10.3.3 *Sample Preparation*

10.3.3.1 In a clean environment, evaporate a 50.0 g sample at low heat until approximately 20 g of the sample remains. Carefully add 1 mL of the ultra pure nitric acid and gently warm for several minutes. Cool to room temperature, add 25 µL of the indium internal standard, and dilute with Type E1.1 water to a final weight of 25.0 g.

10.3.4 *Analysis*

10.3.4.1 Using the prepared solutions and blanks, analyze sodium, potassium, calcium, and iron by graphite furnace atomic absorption (GFAA) and the remaining elements by inductively coupled plasma mass spectrometry (ICP/MS). For calibration, the standards are made up in 4% nitric acid solution with final concentration of 20 ng/g of the indium internal standard. Run a reagent blank.

11 Grade 4 Procedures

NOTE 7: The analytical procedures associated with this standard are not intended to be the only acceptable procedure or the best procedure available. The published procedures have been found to meet the required criteria for acceptance of an analytical procedure. Alternate procedures may be used if they meet the same criteria as the published procedures.

NOTE 8: Each laboratory is responsible for verifying the validity of each method within its own operation.

11.1 *Non-Metal Impurities*

11.1.1 See Section 8, which contains procedures for the following tests:

Assay

Color (APHA)

Carbon Dioxide

Substances Reducing Permanganate

11.2 *Anions*

11.2.1 The following method has given satisfactory results in determining anion impurities at the values specified for each of the following anions: chloride (Cl), phosphate (PO_4), nitrate (NO_3), and sulfate (SO_4). Alternate methods may be used as long as appropriate studies demonstrate a recovery between 75–125% of a known sample spike for half of the value of each specified anion.

11.2.2 *Reagents*

11.2.2.1 *Eluent* — Prepare an eluent solution that is 2.2 mM sodium carbonate (Na_2CO_3) and 0.75 mM sodium bicarbonate ($NaHCO_3$) in deionized water meeting the criteria for Type E1.1 in ASTM D5127. Store eluent under a helium gas blanket.

11.2.2.2 *Regenerant* — Prepare a 0.025 N sulfuric acid (H_2SO_4) in deionized water meeting the criteria for Type E1.1 in ASTM D5127.

11.2.2.3 *Potassium Carbonate Solution* — Prepare a solution containing 500 mg of reagent grade potassium carbonate (K_2CO_3) in 100 mL of water meeting the criteria for Type E1.1 in ASTM D5127.

11.2.3 *Sample Preparation*

11.2.3.1 In a clean environment, place 200 g of sample into a clean beaker. Add 1 mL of a 5 mg/mL potassium carbonate solution and evaporate carefully (at 100°C) to a volume of 0.5 mL. Dilute with water meeting the criteria for Type E1.1 in ASTM D5127 to a final volume of 20 mL.

11.2.4 *Analysis*

11.2.4.1 Using the prepared solutions and blanks, analyze chloride, nitrate, phosphate, and sulfate by ion chromatography. Run a reagent blank. Samples and reagent blanks should be prepared and analyzed in triplicate.

11.2.4.2 *Columns* — Precolumn should be AG4-A (Dionex) or equivalent, and separation column should be AS4-A (Dionex) or equivalent.

11.3 *Trace Metals Analysis*

11.3.1 The following method has given satisfactory results in determining metal ion impurities at the values specified for each of the following metals: aluminum (Al), antimony (Sb), arsenic (As), boron (B), calcium (Ca), chromium (Cr), copper (Cu), gold (Au), iron (Fe), lead (Pb), magnesium (Mg), manganese (Mn), nickel (Ni), potassium (K), sodium (Na), tin (Sn), titanium (Ti), and zinc (Zn). Alternate methods may be used as long as appropriate studies demonstrate a recovery between 75–125% of a known sample spike for half of the value of each specified element.

11.3.2 *Special Reagents*

11.3.2.1 *Nitric Acid, Ultrapure* — Use nitric acid of low metal ion content.

11.3.2.2 *2% Nitric Acid Solution* — Dilute ultrapure nitric acid with water meeting the criteria for Type E1.1 in ASTM D5127.

11.3.2.3 *Water* — The water used for dilution, calibration, and standards should meet, at a minimum, the criteria for Type E1.1 in ASTM D5127 in regard to cation analysis.

11.3.2.4 *Internal Standard Solution* — Make up an internal standard solution to a concentration of 1000 µg/mL from appropriate concentrated scandium, yttrium, indium, thulium, and thorium standard solutions.

11.3.3 *Sample Preparation*

11.3.3.1 In a clean environment, in a teflon bottle, evaporate a 50.0 g sample at low heat until approximately 5 g of the sample remains. Cool to room temperature, add 100 µL of the internal standard solution, and dilute with 2% nitric acid to a final weight of 10.0 g.

11.3.4 *Analysis*

11.3.4.1 Using the prepared solutions and blanks, calibrate the instrument and analyze calcium, iron, sodium, and potassium by cool plasma inductively coupled plasma mass spectrometry (ICP-MS) and the remaining elements by normal plasma ICP-MS.

11.3.4.2 *Calculations* — All data were reported relative to an appropriate 1.0 µg/L standard and corresponding blank solution. Internal standard corrections were applied to the data.

12 Grade 5 Procedures

12.1 This section does not apply to this chemical.

13 VLSI Grade Procedures

13.1 Specific procedures for this grade do not exist. Refer to Sections 8 and 9 for available procedures.

14 Tier A Procedures

14.1 This section does not apply to this chemical.

15 Tier B Procedures

15.1 This section does not apply to this chemical.

16 Tier C Procedures

16.1 This section does not apply to this chemical.

17 Tier D Procedures

17.1 Standardized test methods are being developed for all parameters at the purity levels indicated. The Process Chemicals Committee considers a test method to be valid if there is a documented recovery study showing a recovery of 75–125%. Recovery is for a known sample spike at 50% of the specified level.

Table 1 Impurity Limits and Other Requirements for Ammonium Hydroxide

NOTE 1: Care must be taken in analyzing particles because of the potential formation of microbubbles.

NOTE 2: Due to the limitations of current particle counters, particle size and number are to be agreed upon between supplier and user. See SEMI C1, Section 3.9 for particle counting methodology.

SEMI C22-0699
GUIDELINE FOR BORON TRIBROMIDE

This guideline was technically approved by the Global Process Chemicals Committee and is the direct responsibility of the North American Process Chemicals Committee. Current edition approved by the North American Regional Standards Committee on April 23, 1999. Initially available on SEMI OnLine May 1999; to be published June 1999. This document replaces SEMI C7.17 in its entirety. Originally published in 1994.

1 Purpose

1.1 The purpose of this document is to standardize requirements for boron tribromide used in the semiconductor industry and testing procedures to support those standards. Test methods have been shown to give statistically valid results. This document also provides guidelines for grades of boron tribromide for which a need has been identified. In the case of the guidelines, the test methods may not have been statistically validated yet.

2 Scope

2.1 The scope of this document is all grades of boron tribromide used in the semiconductor industry.

3 Limitations

3.1 None.

4 Referenced Documents

4.1 None.

5 Terminology

5.1 None.

6 Physical Property (for information only)

Clear Colorless Liquid Density at 20°C	2.54 g/mL

7 Requirements

7.1 The requirements for boron tribromide for Tier A are listed in Table 1.

8 Grade 1 Procedures

8.1 This section does not apply to this chemical.

9 Grade 2 Procedures

9.1 This section does not apply to this chemical.

10 Grade 3 Procedures

10.1 This section does not apply to this chemical.

11 Grade 4 Procedures

11.1 This section does not apply to this chemical.

12 Grade 5 Procedures

12.1 This section does not apply to this chemical.

13 VLSI Grade Procedures

13.1 This section does not apply to this chemical.

14 Tier A Procedures

14.1 Standardized test methods are being developed for all parameters at the purity levels indicated. Until standardized test methods are published, test methodology shall be determined by user and producer. The Process Chemicals Committee considers a test method to be valid only if there is a documented recovery study showing a recovery of 75 - 125%. Recovery is for a known sample spike at 50% of the specified level.

15 Tier B Procedures

15.1 This section does not apply to this chemical.

16 Tier C Procedures

16.1 This section does not apply to this chemical.

17 Tier D Procedures

17.1 This section does not apply to this chemical.

SEMI C23-0301
SPECIFICATIONS FOR BUFFERED OXIDE ETCHANTS

These specifications were technically approved by the Global Process Chemicals Committee and are the direct responsibility of the North American Process Chemicals Committee. Current edition approved by the North American Regional Standards Committee on October 17, 1999. Initially available at www.semi.org February 2001; to be published March 2001. This document replaces SEMI C2.2 and C7.23 in their entirety. Originally published in 1981 and 1997 respectively; previously published June 1999.

1 Purpose

1.1 The purpose of this document is to standardize requirements for buffered oxide etchants used in the semiconductor industry and testing procedures to support those standards. Test methods have been shown to give statistically valid results. This document also provides guidelines for grades of buffered oxide etchants for which a need has been identified. In the case of the guidelines, the test methods may not have been statistically validated yet.

2 Scope

2.1 The scope of this document is all grades of buffered oxide etchants used in the semiconductor industry.

2.2 These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 None.

4 Referenced Documents

4.1 *SEMI Standards*

SEMI C1 — Specifications for Reagents

4.2 *ASTM Standards*[1]

ASTM D5127 — Standard Guide for Ultra Pure Water Used in the Electronics and Semiconductor Industry

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 *buffered oxide etchant* — any combination of ammonium fluoride and hydrofluoric acid in which the concentrations are expressed in terms of the equivalent relative volumes of 40% ammonium fluoride solution and 49% hydrofluoric acid. In the expression, the relative volumes shall be reduced to a ratio of the smallest whole numbers which properly describes the composition. For example, a 7:1 buffered oxide etchant contains the equivalent of 7 volumes of 40.0% ammonium fluoride and 1 volume of 49% hydrofluoric acid.

NOTE 2: Density at temperature.

6 Composition

6.1 For analytical purposes, the absolute concentrations of ammonium fluoride and hydrofluoric acid corresponding to the above definition shall be calculated according to the following equations.

$$\text{Weight \% } NH_4F = \frac{(\text{volume} \times \text{density} \times \text{concentration})\,NH_4F}{(\text{volume} \times \text{density})\,NH_4F + (\text{volume} \times \text{density})\,HF}$$

$$\text{Weight \% HF} = \frac{(\text{volume} \times \text{density} \times \text{concentration})\,HF}{(\text{volume} \times \text{density})\,NH_4F + (\text{volume} \times \text{density})\,HF}$$

where volume and density are expressed in consistent units and concentration is in weight percent to three significant figures.

6.2 Sample calculation for 7:1 buffered oxide etchant using 40.0% ammonium fluoride, density 1.111 g/mL, and 49.0% hydrofluoric acid, density 1.153 g/mL. The absolute percentage concentration of each component follows:

$$\text{Weight \% } NH_4F = \frac{7 \times 1.111 \times 40.0}{7 \times 1.111 + 1 \times 1.153} = 34.8\%$$

$$\text{Weight \% HF} = \frac{1 \times 1.153 \times 49.0}{7 \times 1.111 + 1 \times 1.153} = 6.33\%$$

7 Tolerances

7.1 The tolerances allowed for the absolute percentage of each of the components of a buffered oxide etchant shall be:

Ammonium Fluoride:	± 0.5%
Hydrofluoric Acid:	± 0.15%

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, Pennsylvania 19428-2959, USA. Telephone: 610.832.9585, Fax: 610.832.9555. Website: www.astm.org

7.2 For the example above, the permissible range of concentration for ammonium fluoride shall be 34.8 ± 0.5% and for hydrofluoric acid 6.33 ± 0.15%.

8 Requirements

8.1 The requirements for buffered oxide etchants for Grades 1 and 2 are listed in Table 1.

9 Grade 1 Procedures

9.1 *Hydrofluoric Acid* — Weigh accurately approximately 4.0 grams of sample, transfer to a polyethylene beaker, and dilute with water to about 100 mL. Titrate with standardized 1 N sodium hydroxide. The endpoint may be detected colorimetrically by adding 3 drops of methyl red indicator solution and titrating to a definite yellow (no orange) endpoint. As an alternate method, the endpoint may be detected potentiometrically using an HF resistant pH electrode previously standardized in pH 4 and pH 7 buffers. Titrate to pH 6.5 with continuous stirring. Save the solution for the determination of ammonium fluoride.

$$\%\ \text{Hydrofluoric Acid} = \frac{\text{mL} \times \text{N of NaOH} \times 2.001}{\text{Weight of sample (g)}}$$

9.2 *Ammonium Fluoride* — Add 40 mL of neutralized formaldehyde solution (see Section 9.2.1) to the solution from the preceding test and stir magnetically for 30 minutes. Titrate with standardized 1 N sodium hydroxide. The endpoint may be detected colorimetrically using 10 drops of phenolphthalein indicator and titrating to a stable pink end point. As an alternative method, the endpoint may be detected potentiometrically using an HF resistant electrode previously standardized in pH 7 and 9 buffers. Titrate to pH 8.5 with continuous stirring.

$$\%\ \text{Ammonium Fluoride} = \frac{\text{mL} \times \text{N of NaOH} \times 3.704}{\text{Weight of sample (g)}}$$

9.2.1 *Neutralized Formaldehyde Solution* — Dilute 20 mL of 37% formaldehyde solution with 20 mL of water and neutralize with 0.1 N sodium hydroxide solution to the phenolphthalein endpoint.

9.3 *Arsenic and Antimony (as As)* — To 30 mL (33 g) of sample in a polyfluorocarbon dish, add 20 mL of nitric acid and 5 mL of hydrochloric acid and evaporate in a sand bath in a hood to dryness. Completely volatilize the ammonium fluoride, but do not bake. Add 10 mL of water and 5 mL of sulfuric acid and evaporate to dense fumes of sulfur trioxide. Cool, cautiously add 10 mL of water, and reevaporate to dense fumes of sulfur trioxide. Cool, and cautiously wash into a generator flask with water to make a volume of 35 mL. Proceed as described in the General Method for Arsenic (and Antimony) under SEMI C1, Section 3.4.5, starting with the sentence which begins, “Swirl the flask...” Any red color in the silver diethyldithiocarbamate solution of the sample should not exceed that in the standard containing 0.001 mg of arsenic ion (As).

9.4 *Trace Element Contents* — Determine the levels of specified trace elements and establish that they do not exceed the specification limits using a suitable emission spectrographic procedure (see SEMI C1, Section 3.5, Guidelines for Determination of Trace Elements by Emission Spectrography).

10 Grade 2 Procedures

NOTE 1: Each laboratory is responsible for verifying the validity of the method within its own operation.

10.1 *Hydrofluoric Acid* — Weigh accurately approximately 4.0 grams of sample, transfer to a polyethylene beaker, and dilute with water to about 100 mL. Titrate with standardized 1 N sodium hydroxide. The endpoint may be detected colorimetrically by adding 3 drops of methyl red indicator solution and titrating to a definite yellow (no orange) endpoint. As an alternate method, the endpoint may be detected potentiometrically using an HF resistant pH electrode previously standardized in pH 4 and pH 7 buffers. Titrate to pH 6.5 with continuous stirring. Save the solution for the determination of ammonium fluoride.

$$\%\ \text{Hydrofluoric Acid} = \frac{\text{mL} \times \text{N of NaOH} \times 2.001}{\text{Weight of sample (g)}}$$

10.2 *Ammonium Fluoride* — Add 40 mL of neutralized formaldehyde solution (see Section 10.2.1) to the solution from the preceding test and stir magnetically for 30 minutes. Titrate with standardized 1 N sodium hydroxide. The endpoint may be detected colorimetrically using 10 drops of phenolphthalein indicator and titrating to a stable pink endpoint. As an alternative method, the endpoint may be detected potentiometrically using an HF resistant electrode previously standardized in pH 7 and 9 buffers. Titrate to pH 8.5 with continuous stirring.

$$\%\ \text{Ammonium Fluoride} = \frac{\text{mL} \times \text{N of NaOH} \times 3.704}{\text{Weight of sample (g)}}$$

10.2.1 *Neutralized Formaldehyde Solution* — Dilute 20 mL of 37% formaldehyde solution with 20 mL of water and neutralize with 0.1 N sodium hydroxide solution to the phenolphthalein endpoint.

10.3 *Chloride* — Mix 2.2 mL (2.5 g) of sample with 20 mL of water containing 0.5 g of boric acid. Add 1 mL of nitric acid and 1 mL of silver nitrate reagent solution, and allow to stand for 5 minutes. Any turbidity produced should be no greater than that produced when 0.01 mg of chloride ion (Cl) is treated as the sample.

10.4 *Nitrate* — To 2 mL of water in a white plastic beaker, add 0.9 mL (1g) of sample, 1 mL of sulfuric acid, 0.05 mL of 0.01 N (0.002 M) potassium permanganate, mix, and decolorize with sodium arsenite reagent solution. Dilute to 50 mL with brucine sulfate reagent solution and mix. Heat the solution in a preheated (boiling water) bath for 10 minutes. Cool rapidly in an ice bath to room temperature. The yellow color of the sample should be no greater than that produced when 0.01 mg of nitrate ion (NO_3) is treated as the sample.

10.5 *Phosphate* — To a 9 mL (10 g) sample in a platinum dish, add 1 mL of sodium carbonate reagent solution and 40 mL of nitric acid. Evaporate carefully, to prevent spattering, to near dryness. Cool, wash down the sides of the dish with 5 mL of nitric acid, and evaporate to dryness. Repeat the evaporation with nitric acid two times to ensure complete removal of all the fluoride. To the cooled dish, add 25 mL of 0.5 N sulfuric acid to dissolve the residue, warming if necessary. Cool, transfer to a color comparison tube, and add 1 mL of ammonium molybdate reagent solution, 1 mL of p-(methylamino)phenol sulfate reagent solution, and allow to stand at room temperature for 2 hours. Any blue color should be no greater than that produced when 0.01 mg of phosphate ion (PO_4) is treated as the sample.

10.6 *Sulfate* — To 23 mL (25 g) of sample, add 10 mL of sodium carbonate reagent solution and heat gently until sample has been volatilized. To the residue, add 5 mL of hydrochloric acid and evaporate to dryness in a hood. Dissolve the residue in 10 mL of water and 1 mL of dilute hydrochloric acid (1 + 19); filter if necessary. Add 1 mL of barium chloride reagent solution, mix, and allow to stand for 10 minutes. Any turbidity developed should be no greater than that produced when 0.05 mg of sulfate ion (SO_4) solution is treated as the sample.

10.7 *Trace Metals Analysis*

10.7.1 The following method has given satisfactory results in determining metal ion impurities at the values specified for each of the following metals: aluminum (Al), antimony (Sb), arsenic (As), boron (B), calcium (Ca), chromium (Cr), copper (Cu), gold (Au), iron (Fe), lead (Pb), magnesium (Mg), manganese (Mn), nickel (Ni), potassium (K), silver (Ag), sodium (Na), tin (Sn), titanium (Ti), and zinc (Zn). Alternate methods may be used as long as appropriate studies demonstrate a recovery between 75–125% of a known sample spike for half of the value of each specified element.

10.7.2 *Special Reagents*

10.7.2.1 *Nitric Acid, Ultrapure* — Use nitric acid specified for low metal ion content.

10.7.2.2 *4% Nitric Acid Solution* — Dilute 40 mL of ultrapure nitric acid to 1 L using water meeting the criteria for Type E1.1 in ASTM D5127.

10.7.2.3 *Water* — The water used for all the dilution, calibration, and standards should meet at a minimum the criteria for Type E1.1 in ASTM D5127 in regard to cation analysis.

10.7.2.4 *Indium Internal Standard* — Make up a indium internal standard solution to a concentration of 20 µg/mL (ppm) from an appropriate concentrated indium standard solution.

10.7.3 *Sample Preparation*

10.7.3.1 In a clean environment, weigh 10.0 g sample into a cleaned Teflon beaker and evaporate the sample on a 250°C hotplate to near dryness. Carefully add 1 mL of the ultrapure nitric and 3 mL of water and gently warm for several minutes. Cool to room temperature, add 25 µL of the indium internal standard, and dilute with Type E1.1 water to a final weight of 25.0 g.

10.7.4 *Analysis*

10.7.4.1 Using the prepared solutions and blanks, analyze sodium, potassium, calcium, and iron by graphite furnace atomic absorption (GFAA) and the remaining elements by inductively coupled plasma mass spectrometry (ICP/MS). For calibration, the standards are made up in 4% nitric acid solution with final concentration of 20 ng/g of the indium internal standard. Run a reagent blank.

SEMI C24-0301
SPECIFICATION FOR n-BUTYL ACETATE

This specification was technically approved by the Global Process Chemicals Committee and is the direct responsibility of the North American Process Chemicals Committee. Current edition approved by the North American Regional Standards Committee on October 17, 1999. Initially available at www.semi.org February 2001; to be published March 2001. This document replaces SEMI C1.5 in its entirety. Originally published in 1978; previously published June 1999.

1 Purpose

1.1 The purpose of this document is to standardize requirements for n-butyl acetate used in the semiconductor industry and testing procedures to support those standards. Test methods have been shown to give statistically valid results. This document also provides guidelines for grades of n-butyl acetate for which a need has been identified. In the case of the guidelines, the test methods may not have been statistically validated yet.

2 Scope

2.1 The scope of this document is all grades of n-butyl acetate used in the semiconductor industry.

2.2 These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 None.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI C1 — Specifications for Reagents

4.2 *ASTM Standards*[1]

ASTM D5127 — Standard Guide for Ultra Pure Water Used in the Electronics and Semiconductor Industry

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 None.

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, Pennsylvania 19428-2959, USA. Telephone: 610.832.9585, Fax: 610.832.9555. Website: www.astm.org

6 Physical Property (for information only)

Density at 25°C	0.88 g/mL
Boiling Point	126.5°C

7 Requirements

7.1 The requirements for n-butyl acetate for Grade 1 are listed in Table 1.

8 Grade 1 Procedures

NOTE 2: Each laboratory is responsible for verifying the validity of the method within its own operation.

8.1 *Assay* — Analyze the sample by gas chromatography (see SEMI C1, Section 3.1, Guidelines for Assay by Wide Bore Column Gas Chromatography). The parameters cited have given satisfactory results.

Column: 30 meter ×. 530 micron I.D. fused silica capillary, coated with 5 micron film of DB-1 or equivalent (100% methyl silicone which has been surface bonded and cross linked).

Column Temperature: 40°C isothermal for 5 minutes, then programmed to 200°C at 10°C/min.

Injector Temperature:	150°C
Detector Temperature:	250°C
Sample Size:	0.2 µL splitless
Carrier Gas:	Helium at 3 mL/min
Detector:	Thermal Conductivity
Approximate Retention Times (min):	
Butyl Acetate	8.0

8.2 *Color* — Dilute 3.0 mL of platinum-cobalt stock solution (APHA No. 500) to 100 mL with water. Compare this standard (APHA No. 15) with 100 mL of sample in Nessler tubes. View vertically over a white background. The sample must be no darker than the standard.

8.3 *Acidity* — To 57 mL (50 g) of sample in a 250 mL conical flask, add 0.5 mL of phenolphthalein indicator solution and titrate with 0.1 N alcoholic potassium hydroxide until a slight pink color persists for at least

15 seconds. Not more than 1.0 mL of the potassium hydroxide solution should be required.

8.4 *Residue after Evaporation* — Evaporate 90 mL (80 g) of sample to dryness. Dry at 105°C for 30 minutes, cool in a desiccator, and weigh (see SEMI C1, Section 3.3, Determination of Residue after Evaporation).

8.5 *Water* — Add 25 mL of methanol to a dry titration flask and add Karl Fischer (KF) reagent to a visually or electrometrically determined endpoint that persists for 30 seconds. Add 25 mL (22 g) of sample, taking care to protect the sample and contents of the flask from moisture. Stir vigorously and titrate with Karl Fischer reagent to the same endpoint.

$$\%\ \text{Water}\ (H_2O) = \frac{\text{mL KF reagent} \times \text{KF factor}\ (gH_2O/mL) \times 100}{\text{Weight of sample (g)}}$$

8.6 *Phosphate* — To 11 mL (10 g) of sample, add 10 mL of sodium carbonate reagent solution and evaporate to dryness on a steam bath in a hood. Dissolve the residue in 25 mL of 0.5 N sulfuric acid. Add 1 mL of ammonium molybdate reagent solution and 1 mL of p-(methylamino)phenol sulfate reagent solution. Allow to stand at room temperature for 2 hours. Any blue color should be no greater than that produced when 0.01 mg of phosphate ion (PO_4) is treated as the sample.

8.7 *Arsenic and Antimony (as As)* — Evaporate 45 mL (40 g) of sample in a 150 mL beaker to a small volume in a hood. Add 50 mL of water and again evaporate to a small volume. Repeat the evaporation with water addition. Do not allow to go to dryness. Add 5 mL of nitric acid and 5 mL of sulfuric acid and evaporate to dense fumes of sulfur trioxide. Cool, cautiously add 10 mL of water, and again evaporate to dense fumes of sulfur trioxide. Cool, and cautiously wash into a generator flask with water to make a volume of 35 mL. Proceed as described in the General Method for Arsenic (and Antimony) under SEMI C1, Section 3.4.5, starting with the sentence which begins: "Swirl the flask...." Any red color in the silver diethyldithiocarbamate solution of the sample should be no greater than that of the standard containing 0.002 mg of arsenic (As).

8.8 *Trace Metal Analysis* — The following method has given satisfactory results in determining trace metal impurities at the value specified for each of the following trace metals: aluminum (Al), boron (B), calcium (Ca), chromium (Cr), copper (Cu), gold (Au), iron (Fe), lead (Pb), magnesium (Mg), manganese (Mn), nickel (Ni), potassium (K), sodium (Na), tin (Sn), titanium (Ti), and zinc (Zn). Alternate methods may be used as long as appropriate studies demonstrate recovery between 75–125% of a known sample spike for half of the value of each specified item.

8.8.1 *Special Reagents*

8.8.1.1 *Solution A* — Glycerol (ACS Reagent Grade) 10 g, Adipic Acid (99 + %) 1 g, EDTA Acid (ACS Reagent Grade) 0.1 g. Dilute to 1 L using water meeting the criteria for Type E1.1 in ASTM D5127.

8.8.1.2 *Nitric Acid, Ultra Pure* — Use 70% nitric acid specified for ultra low metal ion content.

8.8.1.3 *2% Nitric Acid Solution* — Dilute 20 mL of ultra pure nitric acid to 1 L using water meeting the criteria for Type E1.1 in ASTM D5127.

8.8.2 *Sample Preparation*

8.8.2.1 In a clean environment, place 250 g of sample in a PTFE dish. Add 50 mL of Solution A. Slowly evaporate in a hot plate avoiding loss of sample by effervescence or spattering until there is no further loss of liquid. Cool. Add 1 mL of ultra pure, 70% nitric acid. While maintaining volume, carefully warm several minutes to dissolve any residue. Cool. Transfer quantitatively to a 50 mL volumetric flask using 2% nitric acid for rinsing and dilution to volume. Run a reagent blank.

8.8.3 *Analysis*

8.8.3.1 Using the prepared sample, analyze group I elements by flame atomic absorption spectroscopy and all other elements by plasma emission spectroscopy. Apply, if necessary, a reagent blank correction to the final determined value of the sample.

NOTE 3: Repeat analysis for tin using larger sample size if the instrument sensitivity is insufficient at the specified limit.

SEMI C25-0699^E
SPECIFICATION FOR DICHLOROMETHANE (METHYLENE CHLORIDE)

This specification was technically approved by the Global Process Chemicals Committee and is the direct responsibility of the North American Process Chemicals Committee. Current edition approved by the North American Regional Standards Committee on April 23, 1999. Initially available on SEMI OnLine May 1999; to be published June 1999. This document replaces SEMI C1.6 in its entirety. Originally published in 1978.

E This document was editorially modified in March 2000. Changes were made to the note following Table 1.

1 Purpose

1.1 The purpose of this document is to standardize requirements for dichloromethane (methylene chloride) used in the semiconductor industry and testing procedures to support those standards. Test methods have been shown to give statistically valid results. This document also provides guidelines for grades of dichloromethane for which a need has been identified. In the case of the guidelines, the test methods may not have been statistically validated yet.

2 Scope

2.1 The scope of this document is all grades of dichloromethane used in the semiconductor industry.

3 Limitations

3.1 None.

4 Referenced Documents

SEMI C1 — Specifications for Reagents

5 Terminology

5.1 None.

6 Physical Property (for information only)

Density at 25°C	1.32 g/mL
Boiling Point	39.8°C

7 Requirements

7.1 The requirements for dichloromethane for Grade 1 are listed in Table 1.

8 Grade 1 Procedures

NOTE 1: Each laboratory is responsible for verifying the validity of the method within its own operation.

8.1 *Assay* — Analyze the sample by gas chromatography (see SEMI C1, Section 3.1, Guidelines for Assay by Wide Bore Column Gas Chromatography). The parameters cited have given satisfactory results.

Column: 30 meter × 530 micron I.D. fused silica capillary, coated with 5 micron film of DB-1 or equivalent (100% methyl silicone which has been surface bonded and cross linked).

Column Temperature: 40°C isothermal for 5 minutes, then programmed to 200°C at 10°C/min.

Injector Temperature:	150°C
Detector Temperature:	250°C
Sample Size:	0.2 µL splitless
Carrier Gas:	Helium at 3 mL/min
Detector:	Thermal Conductivity
Approximate Retention Times (min):	
Dichloromethane	6.0
Chloroform	11.0
Carbon Tetrachloride	14.0

8.2 *Color* — Dilute 2.0 mL of platinum-cobalt stock solution (APHA No. 500) to 100 mL with water. Compare this standard (APHA No. 10) with 100 mL of sample in Nessler tubes. View vertically over a white background. The sample must be no darker than the standard.

8.3 *Acidity* — To 25 mL of water in a glass-stoppered flask, add 10 mL of sample and 0.1 mL of phenolphthalein indicator solution. Add 0.01 N sodium hydroxide until a slight pink color persists after shaking for one-half minute. Add 38 mL (50 g) of the sample, mix well, and titrate with 0.01 N sodium hydroxide until the pink color is reproduced. Not more than 1.0 mL of the sodium hydroxide solution should be required.

8.4 *Residue After Evaporation* — Evaporate 76 mL (100 g) of sample to dryness. Dry at 105°C for 30 minutes, cool in a desiccator, and weigh (see SEMI C1, Section 3.3, Determination of Residue After Evaporation).

8.5 *Water* — Add 25 mL of methanol to a dry titration flask and add Karl Fischer (KF) reagent to a visually or electrometrically determined endpoint that persists for 30 seconds. Add 76 mL (100 g) of sample, taking care to protect the sample and contents of the flask from moisture. Stir vigorously and titrate with Karl Fischer reagent to the same endpoint.

$$\% \text{ Water } (H_2O) = \frac{\text{mL KF reagent} \times \text{KF factor (g } H_2O\text{/mL)} \times 100}{\text{Weight of sample (g)}}$$

8.6 *Chloride* — To a 100 mL separatory funnel, add 30 mL (40 g) of sample and 40 mL of water. Shake well for 30 seconds and allow the two layers to separate. Discard the sample (lower) layer. To a 20 mL portion of the water layer add 1 mL of nitric acid and 1 mL of silver nitrate reagent solution. Any turbidity produced should be no greater than that of a standard containing 0.01 mg of chloride ion (Cl) in an equal volume of solution containing the amounts of reagents used.

8.7 *Phosphate* — To 7.5 mL (10 g) of sample, add 10 mL of sodium carbonate reagent solution and evaporate to dryness on a steam bath in a hood. Dissolve the residue in 25 mL of 0.5 N sulfuric acid. Add 1 mL of ammonium molybdate reagent solution and 1 mL of p-(methylamino)phenol sulfate reagent solution. Allow to stand at room temperature for 2 hours. Any blue color produced should be no greater than that produced when 0.01 mg of phosphate ion (PO_4) is treated as the sample.

8.8 *Heavy Metals (as Pb)* — Evaporate 75 mL (100 g) of sample to dryness on a steam bath in a hood. Dissolve the residue in 3 mL of diluted hydrochloric acid (1 + 1) and dilute with water to 15 mL. If necessary, filter through a small filter and wash the evaporating dish and the filter with 10 mL of water. Dilute to 25 mL with water. For the standard, dilute a solution containing 0.02 mg of lead ion (Pb) and 3 mL of diluted hydrochloric acid (1 + 1) to 25 mL with water. Adjust the pH of both solutions to between 3 and 4 with diluted ammonium hydroxide (10% NH_3) or with acetic acid, and dilute with water to 40 mL. To each solution, add 10 mL of freshly prepared hydrogen sulfide water and compare. The sample solution should be no darker than the standard.

8.9 *Arsenic and Antimony (as As)* — Evaporate 152 mL (200 g) of sample in a 400 mL beaker to a small volume in a hood. Add 50 mL of water and again evaporate to a small volume. Repeat the evaporation with water addition. Do not allow to go to dryness. Add 5 mL of nitric of sulfur trioxide. Cool, cautiously add 10 mL of water, and again evaporate to dense fumes of sulfur trioxide. Cool, and cautiously wash into a generator flask with water to make a volume of 35 mL. Proceed as described in the General Method for Arsenic (and Antimony) under SEMI C1, Section 3.4.5, starting with the sentence which begins: "Swirl the flask...." Any red color in the silver diethyldithiocarbamate solution of the sample should be no greater than that of the standard containing 0.002 mg of arsenic (As).

8.10 *Trace Metal Analysis* — The following method has given satisfactory results in determining trace metal impurities at the value specified for each of the following trace metals: aluminum (Al), boron (B), calcium (Ca), chromium (Cr), copper (Cu), gold (Au), iron (Fe), lead (Pb), magnesium (Mg), manganese (Mn), nickel (Ni), potassium (K), sodium (Na), tin (Sn), titanium (Ti), and zinc (Zn). Alternate methods may be used as long as appropriate studies demonstrate recovery between 75 - 125% of a known sample spike for half of the value of each specified item.

8.10.1 *Special Reagents*

8.10.1.1 *Mixed Acid* — Mix one volume of ultra pure 70% nitric acid with four volumes of ultra pure 37% hydrochloric acid.

8.10.1.2 *Standards* — Composite standards containing 0.5 ppm of each element in 10% v/v mixed acid solution are stable for at least 60 days.

8.10.2 *Sample Preparation* — Place 2.5 mL of mixed acid into a clean 400 mL PTFE beaker. Weigh in 200 g of sample. Put a PTFE-coated stir bar in the solution and put the beaker in a hood. Evaporate the sample under a current of air, meeting class 100 cleanroom specifications, with stirring to ensure continuous contact of the acid and sample. Do not heat the sample to minimize the loss of volatile organo-metallics. Continue to evaporate until near dryness. Add 2.5 mL of mixed acid, mix carefully, and transfer the solution to a 25 mL volumetric flask. Rinse the beaker and dilute to volume with water.

8.10.3 *Analysis*

8.10.3.1 Analyze the sample by plasma emission spectrometry except sodium and potassium by atomic absorption or flame emission within 24 hours of dilution using matrix matched standards. Run a reagent blank and correct the data as necessary.

NOTE 2: The trace metal analysis procedure is provisional, pending second source verification of recovery data. To be completed.

NOTE: Dichloromethane contains 0.0025–0.05% ethanol, cyclohexane, or mixed pentenes as stabilizer.

SEMI C26-0699^E

SPECIFICATION AND GUIDELINE FOR HEXAMETHYLDISILAZANE (HMDS)

This specification and guideline were technically approved by the Global Process Chemicals Committee and are the direct responsibility of the North American Process Chemicals Committee. Current edition approved by the North American Regional Standards Committee on April 23, 1999. Initially available on SEMI OnLine May 1999; to be published June 1999. This document replaces SEMI C1.23 and C7.10 in their entirety. Originally published in 1983 and 1991 respectively.

^{E} This document was editorially modified in April 2000 to correct a formatting error. Changes were made to Table 1.

1 Purpose

1.1 The purpose of this document is to standardize requirements for hexamethyldisilazane used in the semiconductor industry and testing procedures to support those standards. Test methods have been shown to give statistically valid results. This document also provides guidelines for grades of hexamethyldisilazane for which a need has been identified. In the case of the guidelines, the test methods may not have been statistically validated yet.

2 Scope

2.1 The scope of this document is all grades of hexamethyldisilazane used in the semiconductor industry.

3 Limitations

3.1 None.

4 Referenced Documents

SEMI C1 — Specifications for Reagents

5 Terminology

5.1 None.

6 Physical Properties (for information only)

Density at 25°C	0.77 g/mL
Boiling Point	126°C

7 Requirements

7.1 The requirements for hexamethyldisilazane for Grade 1 and Tier A are listed in Table 1.

8 Grade 1 Procedures

8.1 *Assay* — Analyze the sample by gas chromatography (see SEMI C1, Section 3.1, Guidelines for Assay by Wide Bore Columns Gas Chromatography). The parameters cited have given satisfactory results.

Column: 30 meter × 530 micon I.D. fused silica capillary, coated with 5 micron film of DB-1 or equivalent (100% methylsilicone which has been bonded and cross linked).

Column Temperature: 40°C isothermal for 2 minutes, then programmed to 220°C at 10°C/min, and isothermal for 10 minutes.

Injector Temperature:	200°C
Detector Temperature:	300°C
Sample Size:	0.4 µL
Carrier Gas:	Helium at 8 mL/min
Detector:	Thermal Conductivity
Approximate Retention Times (min):	
Hexamethyldisilazane	14.3

8.2 *Trailing Impurities* — Use the chromatogram developed in the assay (see Section 8.1). With the relative retention time for hexamethyldisilazane taken as 1.0, establish the integrated area percents for trailing impurities with relative retention times from 1.3 to 4.0. The total of such trailing impurities should not exceed 0.1%.

8.3 *Appearance* — Place 15 mL of the sample in a 20 × 150 mm test tube and compare with water in a similar tube. Viewed across the column by means of transmitted light, the two liquids should be equal in clarity and free from suspended matter.

8.4 *Color* — Dilute 2.0 mL of platinum-cobalt stock solution (APHA No. 500) to 100 mL with water. Compare this standard (APHA No. 10) with 100 mL of sample in Nessler tubes. View vertically over a white background. The sample should be no darker than the standard.

8.5 *Residue After Evaporation* — Evaporate 130 mL (100 g) of sample to dryness in a hood. Dry at 105°C for one hour, cool in a desiccator, and weigh (see SEMI C1, Section 3.3, Determination of Residue After Evaporation).

8.6 *UV Absorbance* — A UV scan is obtained on all HMDS electronic grade material to determine if any UV absorbing impurities are present: specifically toluene.

8.6.1 *Equipment* — Bausch and Lomb Spectronic 2000 Spectrophotometer or other double beam instrument capable of measurements at 270 nm. Cells - 1 cm path length.

8.6.2 *Reagents* — FC-113 and methanol for UV cell cleaning.

8.6.3 *Procedure* — Using water as the reference and sample cells, establish the baseline between 300 and 270 nm. Remove the water sample from the sample path and replace it with the HMDS sample. Read the absorbance between 300 and 270 nm. The absorbance at 270 nm should read 0.07 to 0.25.

NOTE 1: Oxygen will contribute to the UV absorbance.

NOTE 2: The sample must be at ambient temperature.

NOTE 3: The UV absorbance will increase or decrease with time.

NOTE 4: HMDS is flammable and corrosive.

8.7 *Chloride* — To a 500 mL separatory funnel, add 260 mL (200 g) of sample, 20 mL of water, and 1 mL of sodium hydroxide reagent solution. Shake well for 30 seconds and allow the two layers to separate. Carefully draw off the aqueous (lower) layer into a 250 mL beaker. Repeat the extraction five times and combine the six aqueous extracts. Add 2 mL of nitric acid to acidify the solution and arrange the beaker for magnetic stirring.

8.7.1 Using a pH meter fitted with a silver billet electrode (Beckman #89261, Corning #476065, or equivalent) and a silver/silver chloride reference electrode, determine the apparent pH versus mL readings while titrating the continuously stirred sample solution with 0.01 M methanolic silver nitrate solution. Add the silver nitrate solution in 0.1-0.2 mL increments from a 10 mL buret. Run a total blank. Plot the titration data on linear graph paper or use the second-derivative method to establish the endpoint.

$$\text{ppm Chloride (Cl)} = \frac{(\text{mL sample - mL blank}) \times \text{M of AgNO}_3 \times 35{,}460}{\text{Weight of sample (g)}}$$

8.7.2 *Standard Silver Nitrate in Methanol Solution* — Dissolve 1.700 grams of silver nitrate in absolute methanol and dilute to 1000 mL. Store this solution in an amber bottle and standardize immediately before use against a standard sodium chloride (NaCl) solution using the above second-derivative method.

8.8 *Heavy Metals (as Pb)* — Evaporate 130 mL (100 g) of sample to dryness in a hood. Dissolve the residue in 3 mL of dilute hydrochloric acid (1 + 1) and dilute with water to 15 mL. If necessary, filter through a small filter, washing the evaporating dish and filter with 10 mL of water. Dilute to 25 mL with water. For the standard, dilute a solution containing 0.01 mg of lead ion (Pb) and 3 mL of dilute hydrochloric acid (1 + 1) to 25 mL with water. Adjust the pH of both solutions to between 3 and 4 (using a pH meter) with dilute ammonium hydroxide (10% NH_3) or with 1 N acetic acid, and dilute with water to 40 mL. To each solution, add 10 mL of freshly prepared hydrogen sulfide water and compare. The sample solution should be no darker than the standard.

8.9 *Arsenic and Antimony (as As)* — To a 500 mL separatory funnel, add 260 mL (200 g) of sample, 20 mL of water, and 1 mL of sodium hydroxide reagent solution. Shake well for 30 seconds and allow the two layers to separate. Carefully draw off the aqueous (lower) layer into a 150 mL beaker. Repeat the extraction twice more, combining the three aqueous extracts.

8.9.1 Add 15 mL of nitric acid and 5 mL of sulfuric acid and evaporate to dense fumes of sulfur trioxide. Cool, cautiously add 10 mL of water, and re-evaporate to dense fumes of sulfur trioxide. Cool and cautiously wash into a generator flask with water to make a volume of 35 mL. Proceed as described in the General Method for Arsenic (and Antimony) under SEMI C1, Section 3.4.5, starting with the sentence which begins "Swirl the flask...." Any red color in the silver diethyldithiocarbamate solution of the sample should not exceed that for the standard containing 0.002 mg of arsenic (As).

8.10 *Trace Elements* — By a suitable emission spectrographic procedure, determine for each of the specified trace elements that its content is not greater than the stated specification limit (see SEMI C1, Section 3.5, Guidelines for Determination of Trace Elements by Emission Spectrography).

9 Grade 2 Procedures

9.1 This section does not apply to this chemical.

10 Grade 3 Procedures

10.1 This section does not apply to this chemical.

11 Grade 4 Procedures

11.1 This section does not apply to this chemical.

12 Grade 5 Procedures

12.1 This section does not apply to this chemical.

13 VLSI Grade Procedures

13.1 This section does not apply to this chemical.

14 Tier A Procedures

14.1 Standardized test methods are being developed for all parameters at the purity levels indicated. Until standardized test methods are published, test methodology shall be determined by user and producer. The Process Chemicals Committee considers a test method to be valid only if there is a documented recovery study showing a recovery of 75 - 125%. Recovery is for a known sample spike at 50% of the specified level.

15 Tier B Procedures

15.1 This section does not apply to this chemical.

16 Tier C Procedures

16.1 This section does not apply to this chemical.

17 Tier D Procedures

17.1 This section does not apply to this chemical.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI C27-0301
SPECIFICATIONS AND GUIDELINES FOR HYDROCHLORIC ACID

These specifications and guidelines were technically approved by the Global Process Chemicals Committee and are the direct responsibility of the North American Process Chemicals Committee. Current edition approved by the North American Regional Standards Committee by letter ballot dated October 17, 1999. Initially available at www.semi.org February 2001; to be published March 2001. This document replaces SEMI C1.7, C7.2, C8.2, C11.6, and C12.2 in their entirety. Originally published in 1978, 1990, 1992, 1996, and 1995 respectively; previously published June 2000.

1 Purpose

1.1 The purpose of this document is to standardize requirements for hydrochloric acid used in the semiconductor industry and testing procedures to support those standards. Test methods have been shown to give statistically valid results. This document also provides guidelines for grades of hydrochloric acid for which a need has been identified. In the case of the guidelines, the test methods may not have been statistically validated yet.

2 Scope

2.1 The scope of this document is all grades of hydrochloric acid used in the semiconductor industry.

2.2 The VLSI grade purity level is typically required by semiconductor devices with geometries of 0.8–1.2 microns.

2.3 These specifications and guidelines do not purport to address safety issues, if any, associated with their use. It is the responsibility of the users of these specifications and guidelines to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 None.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI C1 — Specifications for Reagents

4.2 *ASTM Standards*[1]

ASTM D5127 — Standard Guide for Ultra Pure Water Used in the Electronics and Semiconductor Industry

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 None.

6 Physical Property (for information only)

Density at 25°C	1.19 g/mL

7 Requirements

7.1 The requirements for hydrochloric acid for Grades 1 and 2, VLSI Grade, and Tiers B and C are listed in Table 1.

8 Grade 1 Procedures

NOTE 2: Each laboratory is responsible for verifying the validity of the method within its own operation.

8.1 *Assay* — Accurately weigh a glass-stoppered conical flask containing about 30 mL of water. Deliver from a pipet about 3 mL of sample near the water surface, stopper immediately, and reweigh. Dilute to about 50 mL with water, add methyl orange indicator solution, and titrate with standardized 1 N sodium hydroxide to a red-to-yellow color change.

$$\%\text{Assay} = \frac{\text{mL} \times \text{N of NaOH} \times 3.646}{\text{Weight of sample (g)}}$$

8.2 *Color* — Dilute 2.0 mL of platinum-cobalt stock solution (APHA No. 500) to 100 mL with water. Compare this standard (APHA No. 10) with 100 mL of sample in Nessler tubes. View vertically over a white background. The sample must be no darker than the standard.

8.3 *Extractable Organic Substances* — Cool 110 mL of sample in an ice bath. Add 5 mL of 2,2,4-trimethylpentane and 100 mL of water to each of two 250 mL separatory funnels. To a third funnel add 100 mL of water and 5 mL of the standard (see below). To the first funnel add 100 mL of the cooled sample, and 100 mL of water to each of the remaining two. Stopper, shake well, and allow the layers to separate. Inject 1.0 µL of each of the 2,2,4-trimethylpentane extracts into a gas chromatograph with a flame ionization detector. The following conditions have been found to be satisfactory: Column — 20% Carbowax® 20 M on

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, Pennsylvania 19428-2959, USA. Telephone: 610.832.9585, Fax: 610.832.9555. Website: www.astm.org

Chromosorb P (80/100), 3 m × 3 mm stainless steel or glass; injection port at 280°C with glass insert; column temperature initially 65°C, programmed at 6°C/min up to 140°C; carrier gas — nitrogen at 40 mL/min; signal adjusted to give an 80% full-scale deflection; and preferably, electronic integration of peak areas. For DDT: Column — 5% silicone gum SESE-30 on Chromosorb® W (60/80), 1.5 × 3 mm, injection port — as above; column temperature — isothermal at 205°C; carrier gas — nitrogen at 75 mL/min, and preferably, electronic integration of peak areas. The order of elution is 2,2,4-trimethylpentane, carbon tetrachloride, benzene, chloroform, 2,2,4-trimethylpentane impurity, 1,2-dichloroethane, chlorobenzene, and dichlorobenzene. The total area under the impurity peaks from the sample should be no greater than that from the blank (extract from second funnel) by more than one-half the total area under the peaks from the standard (third funnel), also corrected for the blank.

8.3.1 *Standard* — Use a syringe to add the volumes of liquid listed in Table 2 into 300 mL of 2,2,4-trimethylpentane. Add 25 mg of DDT to the solution. Dilute to 500 mL with 2,2,4-trimethylpentane. The 2,2,4-trimethylpentane used for both the standard and the analysis should be free from impurities that interfere with the chromatographic analysis.

8.4 *Free Halogen (as Cl_2)* — Mix 100 mL of sample and 100 mL of freshly boiled water and cool. Add 0.1 mL of 2% potassium iodide reagent solution and 1 mL of carbon disulfide, and mix. The carbon disulfide should not acquire a pink color in one-half minute.

8.5 *Phosphate* — To 170 mL (200 g) of sample, add 10 mL of sodium carbonate reagent solution and evaporate to dryness on a steam bath in a hood. Dissolve the residue in 25 mL of 0.5 N sulfuric acid. Add 1 mL of ammonium molybdate reagent solution and 1 mL of p-(methylamino)phenol solution. Allow to stand at room temperature for 2 hours. Any blue color produced should be no greater than that produced when 0.01 mg of phosphate ion (PO_4) is treated like the sample.

8.6 *Sulfate* — To 84 mL (100 g) of sample, add 10 mL of sodium carbonate reagent solution and evaporate to dryness in a hood. Dissolve the residue in 10 mL of water and 1 mL of dilute hydrochloric acid (1 + 19); filter, if necessary. Add 1 mL of barium chloride reagent solution, mix, and allow to stand 10 minutes. Any turbidity should be no greater than that produced when 0.05 mg of sulfate ion (SO_4) is treated as the sample.

8.7 *Sulfite* — Add 1 mL of 10 percent potassium iodide reagent solution, 5 mL of hydrochloric acid, and 2 mL of starch indicator solution to 400 mL of oxygen-free water. Add 0.01 N iodine until a faint permanent blue color is produced. Add 85 mL of the sample and titrate with 0.01 N iodine to the same endpoint. Not more than 0.20 mL should be required.

8.8 *Arsenic and Antimony (as As)* — To 168 mL (200 g) of sample in a 400 mL beaker, add 10 mL of nitric acid and 5 mL of sulfuric acid, and evaporate to dense fumes of sulfur trioxide in a hood. Cool, cautiously add 10 mL of water, and again evaporate to dense fumes of sulfur trioxide. Cool and cautiously wash into a generator flask with water to make a volume of 35 mL. Proceed as described in the General Method for Arsenic (and Antimony) under SEMI C1, Section 3.4.5, starting with tile sentence which begins: “Swirl the flask....” Any red color in the silver diethyldithiocarbamate solution from the sample should be no greater than that of the standard containing 0.001 mg of arsenic (As).

8.9 *Trace Metal Analysis* — The following method has given satisfactory results in determing trace metal impurities at the value specified for each of the following trace metals: aluminum (Al), boron (B), calcium (Ca), chromium (Cr), copper (Cu), gold (Au), iron (Fe), lead (Pb), magnesium (Mg), manganese (Mn), nickel (Ni), potassium (K), sodium (Na), tin (Sn), titanium (Ti), and zinc (Zn). Alternate methods may be used as long as appropriate studies demonstrate recovery between 75 — 125% of a known sample spike for half of the value of each specified item.

8.9.1 *Special Reagents*

8.9.1.1 *Nitric Acid, Ultra Pure* — Use nitric acid specified for ultra low metal ion content.

8.9.1.2 *2% Nitric Acid Solution* — Dilute 20 mL of ultra pure nitric acid to 1 L using water meeting the criteria for Type E1.1 in ASTM D5127.

8.9.2 *Sample Preparation*

8.9.2.1 In a clean environment, place 250 mL of sample in a PTFE evaporating dish. Slowly evaporate on a hot plate, avoiding loss of sample by effervescence or spattering until approximately 2 mL of liquid remains. Note: Evaporation typically requires 2 1/2 to 4 hours. Cool. Transfer quantitatively to a 50 mL volumetric flask using 2% nitric acid for rinsing and dilution to volume. Run a reagent blank.

8.9.3 *Analysis*

8.9.3.1 Using the acid sample and reagent blank, analyze group 1 elements by flame atomic absorption spectroscopy and all other elements by plasma emission spectroscopy.

9 Grade 2 Procedures

NOTE 2: Each laboratory is responsible for verifying the validity of the method within its own operation.

9.1 *Non-Metal Impurities* — See Section 8, which contains procedures for the following tests:

Assay

Color (APHA)

Free Halogen

Phosphate

Sulfate

Sulfite

9.2 *Trace Metals Analysis*

9.2.1 The following method has given satisfactory results in determining metal ion impurities at the values specified for each of the following metals: aluminum (Al), antimony (Sb), arsenic (As) barium (Ba), beryllium (Be), bismuth (Bi), boron (B), calcium (Ca), chromium (Cr), cobalt (Co), copper (Cu), gallium (Ga), germanium (Ge), gold (Au), iron (Fe), lead (Pb), lithium (Li), magnesium (Mg), manganese (Mn), molybdenum (Mo), nickel (Ni), niobium (Nb), potassium (K), silver (Ag), sodium (Na), strontium (Sr), tantalum (Ta), tin (Sn), titanium (Ti), vanadium (V), zinc (Zn), and zirconium (Zr). Alternate methods may be used as long as appropriate studies demonstrate a recovery between 75–125% of a known sample spike for half of the value of each specified element.

9.2.2 *Special Reagents*

9.2.2.1 *Hydrochloric Acid, Ultrapure* — Use hydrochloric acid specified for low metal ion content.

9.2.2.2 *3.7% Hydrochloric Acid Solution* — Dilute 20 g of ultrapure hydrochloric acid to 200 g using water meeting the criteria for Type E1.1 in ASTM D5127.

9.2.2.3 *Nitric Acid, Ultrapure* — Use nitric acid specified for low metal ion content.

9.2.2.4 *1% Nitric Acid Solution* — Dilute 10 mL of ultrapure nitric acid to 1 L using water meeting the criteria for Type E1.1 in ASTM D5127.

9.2.2.5 *Water* — The water used for all the dilution, calibration and standards should meet at a minimum the criteria for Type E1.1 in ASTM D5127 in regard to cation analysis.

9.2.2.6 *Rhodium Internal Standard* — Make up the internal standard solution to a concentration of 20 µg/mL (ppm) from the appropriate concentrated standard rhodium solution.

9.2.3 *Sample Preparation*

9.2.3.1 In a clean environment, place 2.00 g of sample into a tared FEP bottle (30 mL), dilute with "attainable" water to a final weight of 20.0 g. Add 20 µL of the rhodium internal standard solution. Run a reagent blank.

9.2.3.2 *Vanadium* — In a clean environment, place 20.0 g of sample into a clean PTFE dish. Slowly evaporate on a hot plate to dryness avoiding loss of sample by effervescence or spattering. Dissolve the residue with 5 mL of the 1% nitric acid solution by heating on a hot plate at low temperature for several minutes. Cool to room temperature, dilute to 20 g with 1% nitric acid, add 20 µL of the rhodium internal standard, mix well. Run a reagent blank.

9.2.4 *Analysis*

9.2.4.1 Using the prepared solutions and blanks, analyze sodium, potassium, calcium and iron by graphite furnace atomic absorption (GFAA) and the remaining elements by inductively coupled plasma mass spectrometry (ICP/MS). For calibration, the standards are made up with the 3.7% hydrochloric acid solution and the rhodium internal standard except for the analysis of vanadium which is performed using 1% nitric acid as the matrix. All standards must contain 10 ng/g of rhodium as the internal standard.

10 Grade 3 Procedures

10.1 This section does not apply to this chemical.

11 Grade 4 Procedures

11.1 This section does not apply to this chemical.

12 Grade 5 Procedures

12.1 This section does not apply to this chemical.

13 VLSI Grade Procedures

13.1 Specific procedures for this grade do not exist. Refer to Sections 8 and 9 for available procedures.

14 Tier A Procedures

14.1 This section does not apply to this chemical.

15 Tier B Procedures

15.1 Standardized test methods are being developed for all parameters at the purity levels indicated. Until standardized test methods are published, test methodology shall be determined by user and supplier. The Process Chemicals Committee considers a test method to be valid only if there is a documented recovery study showing a recovery of 75–125%.

Recovery is for a known sample spike at 50% of the specified level.

16 Tier C Procedures

16.1 Standardized test methods are being developed for all parameters at the purity levels indicated. Until standardized test methods are published, test methodology shall be determined by user and producer. The Process Chemicals Committee considers a test method to be valid if there is a documented recovery study showing a recovery of 75–125%. Recovery is for a known sample spike at 50% of the specified level.

17 Tier D Procedures

17.1 This section does not apply to this chemical.

NOTICE: SEMI makes no warranties or representations as to the suitability of the specifications and guidelines set forth herein for any particular application. The determination of the suitability of the specifications and guidelines is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These specifications and guidelines are subject to change without notice.

The user's attention is called to the possibility that compliance with these specifications and guidelines may require use of copyrighted material or of an invention covered by patent rights. By publication of these specifications and guidelines, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in these specifications and guidelines. Users of these specifications and guidelines are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI C28-0301
SPECIFICATIONS AND GUIDELINES FOR HYDROFLUORIC ACID

These specifications and guidelines were technically approved by the Global Process Chemicals Committee and are the direct responsibility of the North American Process Chemicals Committee. Current edition approved by the North American Regional Standards Committee on October 17, 1999. Initially available at www.semi.org February 2001; to be published March 2001. This document replaces SEMI C1.8, C7.3, C8.3, and C11.3 in their entirety. Originally published in 1978, 1990, 1992, and 1994 respectively; previously published June 1999.

1 Purpose

1.1 The purpose of this document is to standardize requirements for hydrofluoric acid used in the semiconductor industry and testing procedures to support those standards. Test methods have been shown to give statistically valid results. This document also provides guidelines for grades of hydrofluoric acid for which a need has been identified. In the case of the guidelines, the test methods may not have been statistically validated yet.

2 Scope

2.1 The scope of this document is all grades of hydrofluoric acid used in the semiconductor industry.

2.2 The VLSI grade purity level is typically required by semiconductor devices with geometries of 0.8–1.2 microns.

2.3 These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 None.

DIN 50451, Part 3 — Determination of Trace Metals in Liquids (Aluminum, Cobalt, Copper, Sodium, Nickel, and Zinc in Nitric Acid with ICP-MS)

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 None.

6 Physical Property (for information only)

Density at 25°C	1.15 g/mL

7 Requirements

7.1 The requirements for hydrofluoric acid for Grades 1 and 2, VLSI Grade, and Tier B are listed in Table 1.

8 Grade 1 Procedures

NOTE 2: Each laboratory is responsible for verifying the validity of the method within its own operation.

8.1 *Assay* — Accurately weigh 1.4–1.5 mL of sample in polyethylene weighing bottle, sample, stopper immediately, and reweigh. To 50 mL of water in a plastic vessel, add the sample (loosen the stopper of the polyethylene bottle, and add both the container and the stopper with the sample). Add 0.1 mL of phenolphthalein indicator solution, and titrate with standardized 1 N sodium hydroxide to a slight, pink color.

$$\%Assay = \frac{mL \times N \text{ of NaOH} \times 2.001}{\text{Weight of sample (g)}}$$

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, Pennsylvania 19428-2959, USA. Telephone: 610.832.9585, Fax: 610.832.9555. Website: www.astm.org

2 Deutsches Institut fur Normung e.v.; available from Beuth Verlag GmbH, Burggrafenstrasse 4-10, D-1000 Berlin 30, Germany

8.2 *Color* — Dilute 2.0 mL of platinum-cobalt stock solution (APHA No. 500) to 100 mL with water. Compare this standard (APHA No. 10) with 100 mL of sample in HF resistant plastic tubes. View vertically over a white background. The sample must be no darker than the standard.

8.3 *Fluosilicic Acid* — Weigh 31 mL (36 g) of sample into a large platinum dish. Add 2 g of potassium chloride and 3 mL of hydrochloric acid and evaporate to dryness on a steam bath in a hood. Wash down the sides of the dish with a small amount of water, add 3 mL of hydrochloric acid, and repeat the evaporation. Dissolve the residue in about 100 mL of water, cool to 0°C, and add 0.10 mL of phenolphthalein indicator solution. Neutralize any free acid with 0.1 N sodium hydroxide solution, keeping the temperature of the solution near 0°C. Heat the solution to boiling and titrate with 0.1 N sodium hydroxide. (The 0.1 N sodium hydroxide solution must be stored in a plastic bottle.)

$$\% \; H_2SiF_6 = \frac{\text{mL} \times \text{N of NaOH} \times 3.600}{\text{Weight of sample (g)}}$$

8.4 *Chloride* — Add 1.7 mL (2.0 g) of sample to 45 mL of water. Filter, if necessary, through a chloride-free filter. Add 1 mL of nitric acid and 1 mL of silver nitrate reagent solution. Any turbidity produced should be no greater than that produced when 0.01 mg of chloride ion (Cl) is treated as the sample.

8.5 *Nitrate* — Weigh 3.3 g of sample in a white plastic 50 mL beaker and dilute with 4.5 mL of water. To another 50 mL plastic beaker, add 6.5 mL of water and 1 mL of standard nitrate solution containing 0.01 mg of nitrate (NO_3) per mL. To each solution, add 2.5 mL of brucine sulfate reagent solution and cautiously add with stirring 20 mL of sulfuric acid. Allow to stand for 10 minutes. The yellow color in the sample solution should be no greater than that in the standard solution.

8.6 *Phosphate* — Evaporate 9 mL (10 g) of sample to dryness in a platinum or other suitable dish on a steam bath in a hood. Dissolve the residue in 25 mL of 0.5 N sulfuric acid. Add 1 mL of ammonium molybdate reagent solution and 1 mL of p-(methylamino)phenol sulfate reagent solution. Allow to stand for 2 hours at room temperature. Any blue color should be no greater than that produced when 0.01 mg of phosphate ion (PO_4) is treated like the sample.

8.7 *Sulfate and Sulfite (as SO_4)* — To 18 mL (20 g) of sample in a platinum or other suitable evaporating dish, add about 10 mg of sodium carbonate and 1 mL of 30 hydrogen peroxide. Evaporate to dryness on a steam bath in a hood, wash down the sides of the dish with a small volume of water, and add 3 mL of perchloric acid. Evaporate to about 1 mL, dilute with about 15 mL of water, and add 0.01 mL of phenolphthalein indicator solution. Neutralize with ammonium hydroxide, dilute with water to 20 mL, and add 2 mL of dilute hydrochloric acid (1 + 19) and 2 mL of barium chloride reagent solution. Any turbidity should not exceed that produced by 0.1 mg of sulfate ion (SO_4) in an equal volume of solution containing the quantities of reagents used in the test. Compare 10 minutes after adding the barium chloride to the sample and standard solutions.

8.8 *Arsenic and Antimony (as As)* — To 87 mL (100 g) of sample in a fluoroplastic beaker, add 20 mL of nitric acid, 5 mL of sulfuric acid, and 5 mL of hydrochloric acid; mix gently after each addition. Evaporate to dense fumes of sulfur trioxide in a sand bath in a hood. Cool, cautiously add 10 mL of water, and again evaporate to dense fumes of sulfur trioxide. Cool, and cautiously wash into a generator flask with water to make a volume of 35 mL. Proceed as described in the General Method for Arsenic (and Antimony) under SEMI C1, Section 3.4.5, starting with the sentence which begins: "Swirl the flask...." Any red color should not exceed that in the standard containing 0.003 mg of Arsenic (As).

8.9 *Trace Metal Analysis* — The following method has given satisfactory results in determining trace metal impurities at the value specified for each of the following trace metals: aluminum (Al), boron (B), calcium (Ca), chromium (Cr), copper (Cu), gold (Au), iron (Fe), lead (Pb), magnesium (Mg), manganese (Mn), nickel (Ni), potassium (K), sodium (Na), tin (Sn), titanium (Ti), and zinc (Zn). Alternate methods may be used as long as appropriate studies demonstrate recovery between 75–125% of a known sample spike for half of the value of each specified item.

8.9.1 *Special Reagents*

8.9.1.1 *Nitric Acid, Ultra Pure* — Use nitric acid specified for ultra low metal ion content.

8.9.1.2 *2% Nitric Acid Solution* — Dilute 20 mL of ultra pure nitric acid to 1 L using water meeting the criteria for Type E1.1 in ASTM D5127.

8.9.2 *Sample Preparation*

8.9.2.1 In a clean environment, place 250 g of sample in a PTFE evaporating dish. Slowly evaporate on a hot plate, avoiding loss of sample by effervescence or spattering until approximately 2 mL of liquid remains.

NOTE 3: Evaporation typically requires 2 1/2 to 4 hours. Cool. Add 1 mL of ultra pure, 70% nitric acid. While maintaining volume, carefully warm several minutes to dissolve any residue. Cool. Transfer quantitatively to a 50 mL volumetric flask using 2% nitric acid for rinsing and dilution to volume. Run a reagent blank.

8.9.3 *Analysis*

8.9.3.1 Using the acid sample and reagent blank, analyze group 1 elements by flame atomic absorption spectroscopy and all other elements by plasma emission spectroscopy.

9 Grade 2 Procedures

NOTE 4: Each laboratory is responsible for verifying the validity of the method within its own operation.

9.1 *Non-Metal Impurities* — See Section 8, which contains procedures for the following tests:

Assay

Color (APHA)

Fluosilicic Acid

Chloride

Nitrate

Phosphate

Sulfate and Sulfite (as SO_4)

Arsenic and Antimony (as As)

9.2 *Trace Metals Analysis*

9.2.1 The following method has given satisfactory results in determining metal ion impurities at the values specified for each of the following metals: aluminum (Al), barium (Ba), beryllium (Be), bismuth (Bi), boron (B), calcium (Ca), chromium (Cr), cobalt (Co), copper (Cu), gallium (Ga), germanium (Ge), gold (Au), iron (Fe), lead (Pb), lithium (Li), magnesium (Mg), manganese (Mn), molybdenum (Mo), nickel (Ni), niobium (Nb), potassium (K), silver (Ag), sodium (Na), strontium (Sr), tantalum (Ta), tin (Sn), titanium (Ti), vanadium (V), zinc (Zn) and zirconium (Zr). Alternate methods may be used as long as appropriate studies demonstrate a recovery between 75 - 125% of a known sample spike for half of the value of each specified element.

9.2.2 *Special Reagents*

9.2.2.1 *Hydrofluoric Acid, Ultra Pure* — Use hydrofluoric acid specified for low metal ion content.

9.2.2.2 *4.9% Hydrofluoric Acid Solution* — Dilute 20 g of ultrapure hydrofluoric acid to 200 g using water meeting the criteria for Type E1.1 in ASTM D5127.

9.2.2.3 *Water* — The water used for all the dilution, calibration and standards should meet at a minimum the criteria for Type E1.1 in ASTM D5127 in regard to cation analysis.

9.2.2.4 *Indium Internal Standard* — Make up a internal standard solution to a concentration of 20 µg/mL (ppm) from the appropriate concentrated indium standard solution.

9.2.3 *Sample Preparation*

9.2.4 In a clean environment, place 2.00 g of sample into a tared FEP bottle (30 mL), dilute with Type E1.1 water to a final weight of 20.0 g. Add 20 µL of the indium internal standard solution. Run a reagent blank.

9.2.5 *Analysis*

9.2.5.1 Using the prepared solutions and blanks, analyze sodium, potassium, calcium and iron by graphite furnace atomic absorption (GFAA) and the remaining elements by inductively coupled plasma mass spectrometry (ICP/MS). For calibration, the standards are made up with the 4.9% hydrofluoric acid solution and the indium internal standard such that the final concentration is 20 ng/g of indium.

NOTE 5: Analysis of dilute hydrofluoric acid requires the use of special hydrofluoric acid resistant sample introduction systems for inductively coupled plasma mass spectrometry. These systems are available from most instrument suppliers.

NOTE 6: Analysis of dilute hydrofluoric acid can produce rapid corrosion of nickel cones commonly used in inductively coupled plasma mass spectrometry, platinum cones should be considered as alternative when performing this analysis.

10 Grade 3 Procedures

10.1 This section does not apply to this chemical.

11 Grade 4 Procedures

11.1 This section does not apply to this chemical.

12 Grade 5 Procedures

12.1 This section does not apply to this chemical.

13 VLSI Grade Procedures

13.1 *Assay* — Accurately weigh a polyethylene weighing bottle with stopper containing approximately 20 mL of water, introduce 1.4 – 1.5 mL of sample, stopper immediately, and reweigh to an accuracy of ± 0.0001 g. To 50 mL of water in a 250 mL PE vessel, add the sample (loosen the stopper of the polyethylene bottle, add both the container and the stopper with the sample). Add 0.1 mL of phenolphthalein indicator solution, and titrate with standardized 1 N sodium hydroxide solution to a slight, pink color.

$$\% \text{ Assay} = \frac{1 \text{ mL } 1 \text{ N NaOH} = 0.020006 \text{ g HF}}{\text{Weight of sample (g)}}$$

13.2 *Color* — Dilute 2.0 mL of platinum-cobalt stock solution (APHA No. 500) to 100 mL with water. Compare 50 mL of this standard (APHA No. 10) with 50 mL of sample in HF-resistant plastic tubes. View vertically over a white background. The sample must be no darker than the standard.

13.3 *Residue after Ignition* — Weigh approximately 500 g of sample to an accuracy of ± 0.1 g in separate portions into a tared platinum dish, add 0.5 mL of sulfuric acid, evaporate on an electric heating plate. Ignite at 800°C ± 25°C for 15 minutes. Cool in a desiccator and weigh. Repeat until constant weight is obtained.

13.4 *Fluosilicic Acid* — Weigh approximately 1 g of sample to an accuracy of ± 0.01 g in a 150 mL PE plastic vessel and dilute with water to 60 mL. Add 1 g boron trioxide and stir until the boron trioxide is completely dissolved. Measure pH value using a glass electrode and adjust pH to 1.2 ± 0.1 using diluted sulfuric acid (1 + 3 parts by volume). Add 10 mL of ammonium molybdate solution and readjust pH to 1.2 ± 0.1 if necessary. Remove glass electrode and let remain for 15 minutes. Add 10 mL of diluted sulfuric acid and 2 mL of ascorbic acid solution (2%) and transfer to a 100 mL graduated plastic bottle, fill up with water to 100 mL, and mix thoroughly. After 10 minutes, a sample of the solution is measured in 1 cm cuvettes at 815 nm against a blank solution. The result is calculated on the basis of a previously recorded calibration curve.

13.5 *Chloride* — To 20 g of sample, weighed to an accuracy of ± 0.1 g, add 45 mL of water, 5 mL of dilute nitric acid (25%), and 2 mL of silver nitrate reagent solution (0.1 mol/L). Dilute to 70 mL with water. Any turbidity produced after 15 minutes should not be greater than that produced when 0.002 mg of chloride ion (Cl) is treated as the sample.

13.6 *Nitrate* — Weigh 2 g of sample to an accuracy of ± 0.1 g in a 50 mL white plastic beaker and dilute with 4.5 mL of water. To another 50 mL plastic beaker, add 6.5 mL of water and 1 mL of standard nitrate solution containing 0.01 mg of nitrate (NO_3) per mL. To each solution, add 2.5 mL of brucine sulfate reagent solution and cautiously add with stirring 20 mL of sulfuric acid. Allow to stand for 10 minutes. The yellow color in the sample solution should be no greater than that in the standard solution.

13.7 *Phosphate* — Phosphate is determined by ion chromatography together with sulfate.

13.7.1 To 50 g of sample weighed to an accuracy of ± 0.1 g, add 20 mg sodium carbonate (10 mL of sodium carbonate stock solution 1 g/500 mL) and evaporate the sample to dryness in a platinum dish. Add 10 mL of hydrochloric acid (37%) and again evaporate to dryness. Dissolve the residue in 5 mL of water and directly inject into the instrument. Reference is made using a solution containing 1 ppm phosphate.

13.8 *Sulfate* — Sulfate is determined using ion chromatography after the procedure described in Section 6.7. The results are calculated from a reference solution containing 5 ppm of sulfate.

13.9 *Sulfite (SO_3)* — Weigh 200 g of sample to an accuracy of ± 0.1 g into a 250 mL plastic vessel. Add 50 mL of water and 1 mL of starch solution (1%). Cool and titrate with iodine solution 0.005 mol/L.

NOTE 7: 1.0 mL of iodine solution = 0.40 mg SO_3.

13.10 *Arsenic and Antimony (as As)* — Weigh 30 g of sample to an accuracy of ± 0.1 g into a glass carbon dish. Add 20 mL of nitric acid (65%), 5 mL of sulfuric acid (96%), and 5 mL of hydrochloric acid (37%). Evaporate to dense fumes of sulfur trioxide using an electric surface heater. Cool and cautiously add 10 mL of water and again evaporate to dense fumes of sulfur trioxide. Cool and cautiously wash into a generator flask with water to a volume of 35 mL. Proceed as described in the General Method for Arsenic under SEMI C1, Section 3.4.5. Any red color should not exceed that in the standard containing 0.003 mg of Arsenic (As).

13.11 *Trace Metals Analysis* — Metallic impurities are determined using ICP-MS spectroscopic equipment after a procedure described in DIN 50451, Part 3 with the exception of calcium, iron, potassium, sodium, and vanadium.

13.11.1 Calcium and iron are determined using ICP-OES after a procedure described in DIN 50451, Part 2. Potassium, sodium, and vanadium are determined using graphite furnace atomic absorption after a method described in DIN 50451, Part 1.

13.11.2 *Special Reagents*

13.11.3 *Sample Preparation* — In a clean environment, place 10 – 20 g of sample, weighed to an accuracy of ± 0.1 g, in a PFA evaporating dish. Slowly evaporate on a hot plate, avoiding loss of sample by effervescence or spattering until approximately 500 µL remain. Add 100 µL of ultrapure nitric acid (65%), 50 µL of ultrapure hydrochloric acid (37%), and water. Add 100 µL of lanthanum standard and fill up with water to 10 ± 0.2 g. Run a reagent blank.

NOTE 8: The blank is specified according to SEMI C1, Section 2.6.

13.11.4 *Analysis* — Using the acid sample and reagent blank, analyze elements as described in Section 3.10.

14 Tier A Procedures

14.1 This section does not apply to this chemical.

15 Tier B Procedures

15.1 Standardized test methods are being developed for all parameters at the purity levels indicated. Until standardized test methods are published, test methodology shall be determined by user and producer. The Process Chemicals Committee considers a test method to be valid only if there is a documented recovery study showing a recovery of 75–125%. Recovery is for a known sample spike at 50% of the specified level.

16 Tier C Procedures

16.1 This section does not apply to this chemical.

17 Tier D Procedures

17.1 This section does not apply to this chemical.

Table 1 Impurity Limits and Other Requirements for Hydrofluoric Acid

SEMI C29-0301
SPECIFICATIONS AND GUIDELINE FOR 4.9% HYDROFLUORIC ACID (10:1 v/v)

These specifications and this guideline were technically approved by the Global Process Chemicals Committee and are the direct responsibility of the North American Process Chemicals Committee. Current edition approved by the North American Regional Standards Committee on October 17, 1999. Initially available at www.semi.org February 2001; to be published March 2001. This document replaces SEMI C7.4, C8.4, and C12.3 in their entirety. Originally published in 1990, 1992, and 1995 respectively; previously published June 1999.

1 Purpose

1.1 The purpose of this document is to standardize requirements for 4.9% hydrofluoric acid used in the semiconductor industry and testing procedures to support those standards. Test methods have been shown to give statistically valid results. This document also provides guidelines for grades of 4.9% hydrofluoric acid for which a need has been identified. In the case of the guidelines, the test methods may not have been statistically validated yet.

2 Scope

2.1 The scope of this document is all grades of 4.9% hydrofluoric acid used in the semiconductor industry.

2.2 These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 None.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI C28 — Specifications and Guidelines for Hydrofluoric Acid

4.2 *ASTM Standards*[1]

ASTM D5127 — Standard Guide for Ultra Pure Water Used in the Electronics and Semiconductor Industry

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 None.

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, Pennsylvania 19428-2959, USA. Telephone: 610.832.9585, Fax: 610.832.9555. Website: www.astm.org

6 Physical Property (for information only)

6.1 Not applicable.

7 Requirements

7.1 The requirements for 4.9% hydrofluoric acid for Grades 2 and 3 and Tier C are listed in Table 1.

8 Grade 1 Procedures

8.1 This section does not apply to this chemical.

9 Grade 2 Procedures

NOTE 2: Each laboratory is responsible for verifying the validity of the method within its own operation.

9.1 *Non-Metal Impurities* — See SEMI C28 (Specifications and Guidelines for Hydrofluoric Acid) which contains procedures for the following tests:

Assay

Color (APHA)

Fluosilicic Acid

Chloride

Phosphate

Sulfate and Sulfite (as SO_4)

Arsenic and Antimony (as As)

9.1.1 *Analysis of Anions and Fluosilicic Acid* — Application of the procedures cited above to dilute hydrofluoric acid requires a tenfold increase in the amount of initial sample weight prior to the evaporation steps given in the procedures.

9.2 *Trace Metals Analysis*

9.2.1 The following method has given satisfactory results in determining metal ion impurities at the values specified for each of the following metals: aluminum (Al), arsenic (As), antimony (Sb), barium (Ba), beryllium (Be), bismuth (Bi), boron (B), calcium (Ca), chromium (Cr), cobalt (Co), copper (Cu), gallium (Ga), germanium (Ge), gold (Au), iron (Fe), lead (Pb), lithium (Li), magnesium (Mg), manganese (Mn), molybdenum (Mo), nickel (Ni), niobium (Nb), potassium (K), silver (Ag), sodium (Na), strontium (Sr), tantalum (Ta), tin (Sn), titanium (Ti), vanadium (V), zinc (Zn), and zirconium (Zr). Alternate methods may be used as long as appropriate studies demonstrate a recovery between 75–125% of a known sample spike for half of the value of each specified element.

9.2.2 *Special Reagents*

9.2.2.1 *Hydrofluoric Acid, Ultra Pure* — Use hydrofluoric acid specified for low metal ion content.

9.2.2.2 *4.9% Hydrofluoric Acid Solution* — Dilute 20 g of ultrapure hydrofluoric acid to 200 g using water meeting the criteria for Type E1.1 in ASTM D5127.

9.2.2.3 *Water* — The water used for all the dilution, calibration and standards should meet at a minimum the criteria for Type E1.1 in ASTM D5127 in regard to cation analysis.

9.2.2.4 *Indium Internal Standard* — Make up the internal standard solution to a concentration of 20 µg/mL (ppm) from the appropriate concentrated indium standard solution.

9.2.3 *Sample Preparation*

9.2.3.1 In a clean environment, place 20.0 g of sample into a tared FEP bottle (30 mL). Add 20 µL of the indium internal standard solution. Run a reagent blank.

9.2.4 *Analysis*

9.2.4.1 Using the prepared solutions and blanks, analyze sodium, potassium, calcium and iron by graphite furnace atomic absorption (GFAA) and the remaining elements by inductively coupled plasma mass spectrometry (ICP/MS). For calibration, the standards are made up with the 4.9% hydrofluoric acid solution and a final concentration of 20 ng/g of the indium internal standard.

NOTE 3: Analysis of diluted hydrofluoric acid requires the use of special hydrofluoric acid resistant sample introduction systems for inductively coupled plasma mass spectrometry. These systems are available from most instrument suppliers.

NOTE 4: Analysis of diluted hydrofluoric acid can produce rapid corrosion of nickel cones commonly used in inductively coupled plasma mass spectrometry, platinum cones should be considered as alternative when performing this analysis.

10 Grade 3 Procedures

NOTE 5: The analytical procedures associated with this standard are not intended to be the only acceptable procedure or the best procedure available. The published procedures have been found to meet the required criteria for acceptance of an analytical procedure. Alternate procedures may be used if they meet the same criteria as the published procedures.

NOTE 6: Each laboratory is responsible for verifying the validity of each method within its own operation.

10.1 *Non-Metal Impurities* — See SEMI C28, which contains procedures for the following tests:

Assay

Color (APHA)

Fluosilicic Acid

Chlorides

Phosphates

Sulfate and Sulfite (as SO_4)

10.1.1 *Analysis of Anions and Fluosilicic Acid* — Application of the procedures cited above to dilute hydrofluoric acid requires a tenfold increase in the amount of inital sample weight prior to the evaporation steps given in the procedures.

10.2 *Trace Metals Analysis*

10.2.1 The following method has given satisfactory results in determining metal ion impurities at the values specified for each of the following metals: aluminum (Al), antimony (Sb), arsenic (As), barium (Ba), boron (B), cadmium (Cd), calcium (Ca), chromium (Cr), cobalt (Co), copper (Cu), gold (Au), iron (Fe), lead (Pb), lithium (Li), magnesium (Mg), manganese (Mn), molybdenum (Mo), nickel (Ni), potassium (K), silver (Ag), sodium (Na), strontium (Sr), tin (Sn), titanium (Ti), vanadium (V), and zinc (Zn). Alternate methods may be used as long as appropriate studies demonstrate a recovery between 75–125% of a known sample spike for half of the value of each specified element.

10.2.2 *Special Reagents*

10.2.2.1 *Hydrofluoric Acid, Ultrapure* — Use hydrofluoric acid specified for low metal ion content.

10.2.2.2 *4.9% Hydrofluoric Acid Solution* — Dilute 20 g of ultrapure hydrofluoric acid to 200 g using water meeting the criteria for Type E1.1 in ASTM D5127.

10.2.2.3 *Water* — The water used for all the dilution, calibration, and standards should meet at a minimum the criteria for Type E1.1 in ASTM D5127in regard to cation analysis.

10.2.2.4 *Indium Internal Standard* — Make up the internal standard solution to a concentration of 20 µg/mL (ppm) from the appropriate concentrated indium standard solution.

10.2.3 *Sample Preparation*

10.2.3.1 In a clean environment, place 20.0 g of sample into a tared FEP bottle (30 mL). Add 20 µL of the indium internal standard solution. Run a reagent blank.

10.2.4 *Analysis*

10.2.4.1 Using the prepared solutions and blanks, analyze sodium, potassium, calcium, and iron by graphite furnace atomic absorption (GFAA) and the remaining elements by inductively coupled plasma mass spectrometry (ICP/MS). For calibration, the standards are made up with the 4.9% hydrofluoric acid solution and a final concentration of 20 ng/g of the indium internal standard.

NOTE 7: Analysis of dilute hydrofluoric acid requires the use of special hydrofluoric acid-resistant sample introduction systems for inductively coupled plasma mass spectrometry. These systems are available from most instrument suppliers.

NOTE 8: Analysis of dilute hydrofluoric acid can produce rapid corrosion of nickel cones commonly used in inductively coupled plasma mass spectrometry; platinum cones should be considered as an alternative when performing this analysis.

11 Grade 4 Procedures

11.1 This section does not apply to this chemical.

12 Grade 5 Procedures

12.1 This section does not apply to this chemical.

13 VLSI Grade Procedures

13.1 This section does not apply to this chemical.

14 Tier A Procedures

14.1 This section does not apply to this chemical.

15 Tier B Procedures

15.1 This section does not apply to this chemical.

16 Tier C Procedures

16.1 Standardized test methods are being developed for all parameters at the purity levels indicated. Until standardized test methods are published, test methodology shall be determined by user and producer. The Process Chemicals Committee considers a test method to be valid if there is a documented recovery study showing a recovery of 75–125%. Recovery is for a known sample spike at 50% of the specified level.

17 Tier D Procedures

17.1 This section does not apply to this chemical.

SEMI C30-1101
SPECIFICATIONS AND GUIDELINES FOR HYDROGEN PEROXIDE

These specifications and guidelines were technically approved by the Global Process Chemicals Committee and are the direct responsibility of the North American Process Chemicals Committee. Current edition approved by the North American Regional Standards Committee on August 27, 2001. Initially available at www.semi.org September 2001; to be published November 2001. This document replaces SEMI C1.9, C7.5, C8.5, C11.4, and C12.4 in their entirety. Originally published in 1978, 1990, 1992, 1994, and 1995 respectively; previously published March 2001.

1 Purpose

1.1 The purpose of this document is to standardize requirements for hydrogen peroxide used in the semiconductor industry and testing procedures to support those standards. Test methods have been shown to give statistically valid results. This document also provides guidelines for grades of hydrogen peroxide for which a need has been identified. In the case of the guidelines, the test methods may not have been statistically validated yet.

2 Scope

2.1 The scope of this document is all grades of hydrogen peroxide used in the semiconductor industry.

2.2 The VLSI grade purity level is typically required by semiconductor devices with geometries of 0.8–1.2 microns.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 The specification for VLSI grade hydrogen peroxide is only applicable for materials that remain below 25°C during transport and storage.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI C1 — Specifications for Reagents

4.2 *ASTM Standards*[1]

ASTM D 5127 — Standard Guide for Ultra Pure Water Used in the Electronics and Semiconductor Industry

NOTE 1: Unless otherwise indicated, all documents cited shall be the latest published versions.

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, Pennsylvania 19428-2959, USA. Telephone: 610.832.9585, Fax: 610.832.9555 Website: www.astm.org

5 Terminology

5.1 None.

6 Physical Property (for information only)

Density at 25°C	1.11 g/mL

7 Requirements

7.1 The requirements for hydrogen peroxide for Grades 1, 2, 3, 4, 5, and VLSI Grade are listed in Table 1.

8 Grade 1 Procedures

NOTE 2: When hydrogen peroxide is added to water, there is no spattering. This happens only when the order of addition is reversed.

NOTE 3: Each laboratory is responsible for verifying the validity of the method within its own operation.

8.1 *Assay* — Accurately weigh about 1 mL of sample in a tared 100 mL volumetric flask, dilute to volume with water, and mix thoroughly. Transfer exactly 20.0 mL of this solution to a 250 mL conical flask, add 20 mL of dilute sulfuric acid (1 + 15), and titrate with standardized 0.1 N (0.02 M) potassium permanganate to a pink color that persists for 15 seconds.

$$\%\text{Assay} = \frac{\text{mL} \times \text{N of KMnO}_4 \times 8.500}{\text{Weight of sample (g)}}$$

8.2 *Color* — Dilute 2.0 mL of platinum-cobalt stock solution (APHA No. 500) to 100 mL with water. Compare this standard (APHA No. 10) with 100 mL of sample in Nessler tubes. View vertically over a white background. The sample must be no darker than the standard.

8.3 *Free Acid* — Dilute 9 mL (10 g) of sample with 90 mL of freshly boiled and cooled carbon dioxide-free water. Add 0.15 mL of methyl red indicator solution and titrate with 0.01 N sodium hydroxide. The volume of sodium hydroxide solution consumed should not be more than 0.6 mL greater than the volume required for a blank test on 90 mL of the water used for dilution.

8.4 *TOC*

8.4.1 *Equipment*

8.4.1.1 TOC analyzer capable of analyzing total organic carbon in water.

8.4.1.2 Platinum sheet 1 × 1 inch, heated in a muffle oven at 800°C for 15 minutes.

8.4.2 *Special Reagents*

8.4.2.1 *Water* — The water used for all of the dilution, calibration, and standards should meet, at a minimum, the criteria for Type E1.1 in ASTM D 5127 in regard to TOC analysis.

8.4.2.2 *1000 mg/mL TOC Standard (prepare fresh weekly)* — Weigh accurately 0.2128 g of potassium acid phthalate into a 100 mL volumetric flask, add water, shake to dissolve, dilute to volume, and mix well. Lower standards (prepare fresh daily) can be made by diluting an aliquot of the 1000 mg/mL to the appropriate volume.

8.4.3 *Sample Preparation* — Weigh 50 g of hydrogen peroxide, to the nearest 0.01 g, into a 400 mL beaker. Add the platinum sheet to the sample, cover the beaker with a Teflon watch glass, and allow the reaction to go overnight (12 hours minimum). Transfer the solution to a 50 mL volumetric flask, and dilute with water meeting the criteria for Type E1.1 in ASTM D 5127 to a final volume of 50 mL.

8.4.4 *Analysis* — Using the prepared solutions, analyze TOC by the total organic carbon analyzer after the instrument has been calibrated with 0, 4, 10, and 20 μg/mL of TOC standards.

8.5 *Chloride* — Dilute 4.5 mL (5 g) of sample with 15 mL of water. Filter, if necessary, through a chloride-free filter. Add 1 mL of nitric acid and 1 mL of silver nitrate reagent solution. Any turbidity produced should be no greater than that produced when 0.01 mg of chloride ion (Cl) is treated as the sample.

8.6 *Sulfate* — To 9 mL (10 g) of sample, add 10 mL of sodium carbonate reagent solution and evaporate to dryness in a hood. Dissolve the residue in 10 mL of water and 1 mL of dilute hydrochloric acid (1 + 19); filter if necessary. Add 1 mL of barium chloride reagent solution, mix, and allow to stand for 10 minutes. Any turbidity developed should be no greater than that produced when 0.05 mg of sulfate ion (SO_4) is treated as the sample.

8.7 *Phosphate* — Evaporate 4.5 mL (5 g) of sample to dryness on the steam bath and dissolve the residue in 25 mL of 0.5 N sulfuric acid. Add 1 mL of ammonium molybdate reagent solution and 1 mL of p-(methylamino)phenol sulfate reagent solution. Allow to stand for 2 hours at room temperature. Any blue color should not exceed that produced in a standard of equal volume containing 0.01 mg of phosphate ion (PO_4) and the quantities of reagents used in the sample.

8.8 *Arsenic and Antimony (as As)* — To 180 mL (200 g) of sample in a 400 mL beaker, add 5 mL of sulfuric acid and evaporate to dense fumes of sulfur trioxide in a hood. Cool, cautiously add 10 mL of water, and again evaporate to dense fumes of sulfur trioxide. Cool, and cautiously wash into a generator flask with water to make a volume of 35 mL. Proceed as described in General Method for Arsenic (and Antimony) under SEMI C1, Section 3.4.5, starting with the first sentence which begins: “Swirl the flask....” Any red color in the silver diethyldithiocarbamate solution from the sample should be no greater than that of the standard containing 0.002 mg of arsenic (As).

8.9 *Trace Metal Analysis* — The following method has given satisfactory results in determining trace metal impurities at the value specified for each of the following trace metals: aluminum (Al), boron (B), calcium (Ca), chromium (Cr), copper (Cu), gold (Au), iron (Fe), lead (Pb), magnesium (Mg), manganese (Mn), nickel (Ni), potassium (K), sodium (Na), tin (Sn), titanium (Ti), and zinc (Zn). Alternate methods may be used as long as appropriate studies demonstrate recovery between 75–125% of a known sample spike for half of the value of each specified element.

8.9.1 *Special Reagents*

8.9.1.1 *Nitric Acid, Ultra Pure* — Use nitric acid specified for ultra low metal ion content.

8.9.1.2 *Hydrochloric Acid, Ultra Pure* — Use hydrochloric acid specified for ultra low metal ion content.

8.9.2 *Sample Preparation*

8.9.2.1 *Sodium and Potassium* — In a clean environment, place 10.0 mL of water in a clean platinum crucible. Slowly add 5.0 mL of hydrogen peroxide. Allow to stand at room temperature until the effervescence ceases (approximately 20 minutes). Swirl. If swirling does not produce any more bubbles, proceed with analysis. If bubbles remain, allow to stand for 5 minutes and repeat the swirl until no bubbles are produced. Run a water blank.

8.9.2.2 *Other Elements* — Two separate samples of hydrogen peroxide are acidified to 2% with hydrochloric acid for the analysis of tin and to 2% with nitric acid for the analysis of (specified elements). Standard additions of tin to the matrix acidified with hydrochloric acid and standard additions of other specified elements to the matrix acidified with nitric acid are added to determine the response for each element in the peroxide matrix. Aqueous acidified standards for tin in 2% hydrochloric acid and other specified elements in 2% nitric acid should be used to determine instrument responses.

8.9.3 *Analysis*

8.9.3.1 Using the solution from Section 8.9.2.1, analyze for specified group 1 elements by flame atomic absorption spectroscopy. All other elements analyzed by plasma emission spectroscopy.

9 Grade 2 Procedures

NOTE 4: Each laboratory is responsible for verifying the validity of the method within its own operation.

9.1 *Non-Metal Impurities*

9.1.1 See Section 8, which contains procedures for the following tests:

Assay

Color (APHA)

Free Acid

9.2 *TOC*

9.2.1 *Equipment*

9.2.1.1 TOC analyzer capable of analyzing total organic carbon in water.

9.2.1.2 Platinum sheet 1 × 1 inch, heated in a muffle oven at 800°C for 15 minutes.

9.2.2 *Special Reagents*

9.2.2.1 *Water* — The water used for all of the dilution, calibration, and standards should meet, at a minimum, the criteria for Type E1.1 in ASTM D 5127 in regard to TOC analysis.

9.2.2.2 *1000 mg/mL TOC Standard (prepare fresh weekly)* — Weigh accurately 0.2128 g of potassium acid phthalate into a 100 mL volumetric flask, add water, shake to dissolve, dilute to volume, and mix well. Lower standards (prepare fresh daily) can be made by diluting an aliquot of the 1000 mg/mL to the appropriate volume.

9.2.3 *Sample Preparation*

9.2.3.1 Weigh 50 g of hydrogen peroxide, to the nearest 0.01 g, into a 400 mL beaker. Add the platinum sheet to the sample, cover the beaker with a Teflon watch glass, and allow the reaction to go overnight (12 hours minimum). Transfer the solution to a 50 mL volumetric flask, dilute with water, meeting the criteria for Type E1.1 in ASTM D 5127, to a final volume of 50 mL.

9.2.4 *Analysis*

9.2.4.1 Using the prepared solutions, analyze TOC by the total organic carbon analyzer after the instrument has been calibrated with 0, 4, 10, and 20 µg/mL of TOC standards.

9.3 *Anions*

9.3.1 The following method has given satisfactory results in determining anion impurities at the values specified for each of the following anions: chloride (Cl), phosphate (PO_4), nitrate (NO_3), and sulfate (SO_4). Alternate methods may be used as long as appropriate studies demonstrate a recovery between 75–125% of a known sample spike for half of the value of each specified anion.

9.3.2 *Special Reagents*

9.3.2.1 *Eluent* — Prepare an eluent solution that is 2.2 mM sodium carbonate (Na_2CO_3) and 0.75 mM sodium bicarbonate ($NaHCO_3$) in deionized water meeting the criteria for Type E1.1 in ASTM D 5127. Store eluent under a helium gas blanket.

9.3.2.2 *Regenerant* — Prepare a 0.025 N sulfuric acid (H_2SO_4) in deionized water meeting the criteria for Type E1.1 in ASTM D 5127.

9.3.2.3 *Potassium Carbonate Solution* — Prepare a solution containing 500 mg of reagent grade potassium carbonate (K_2CO_3) into 100 mL of water meeting the criteria for Type E1.1 in ASTM D 5127.

9.3.3 *Sample Preparation*

9.3.3.1 In a clean environment, place 40 g of sample into a clean beaker. Add 1 mL of a 5 mg/mL potassium carbonate solution and evaporate carefully (at 100°C) to a volume of 0.5 mL. Dilute with water meeting the criteria for Type E1.1 in ASTM D 5127 to a final volume of 20 mL.

NOTE 5: For safety purposes, a decomposition aid such as a platinum strip should be used.

9.3.4 *Analysis*

9.3.4.1 Using the prepared solutions and blanks, analyze chloride, nitrate, phosphate, and sulfate by ion chromatography. Run a reagent blank. Samples and reagent blanks should be prepared and analyzed in triplicate.

9.3.4.2 *Columns* — Precolumn should be AG4-A (Dionex) or equivalent and Separation column should be AS4-A (Dionex) or equivalent.

9.4 *Trace Metals Analysis*

9.4.1 The following method has given satisfactory results in determining metal ion impurities at the values specified for each of the following metals: aluminum (Al), antimony (Sb), arsenic (As), barium (Ba), beryllium (Be), bismuth (Bi), boron (B), calcium (Ca), chromium (Cr), cobalt (Co), copper (Cu), gallium (Ga), germanium (Ge), gold (Au), iron (Fe), lead (Pb), lithium (Li), magnesium (Mg), manganese (Mn), molybdenum (Mo), nickel (Ni), niobium (Nb), potassium (K), silver (Ag), sodium (Na), strontium (Sr), tantalum (Ta), tin (Sn), titanium (Ti), vanadium (V), zinc (Zn), and zirconium (Zr). Alternate methods may be used as long as appropriate studies demonstrate a recovery between 75–125% of a known sample spike for half of the value of each specified element.

9.4.2 *Special Reagents*

9.4.2.1 *Nitric Acid, Ultra Pure* — Use nitric acid specified for low metal ion content.

9.4.2.2 *1% Nitric Acid Solution* — Dilute 10 mL of ultrapure nitric acid to 1 L of water meeting the criteria for Type E1.1 in ASTM D 5127.

9.4.2.3 *Water* — The water used for all the dilution, calibration, and standards should meet, at a minimum, the criteria for Type E1.1 in ASTM D 5127 in regard to cation analysis.

9.4.2.4 *Indium Internal Standard* — Make up the indium internal standard solution to a concentration of 20 µg/mL (ppm) from the appropriate concentrated indium standard solution.

9.4.3 *Sample Preparation*

9.4.3.1 In a clean environment, place 20 g of sample in a tared FEP bottle, add 20 µL of the indium internal standard.

9.4.4 *Analysis*

9.4.4.1 Using the prepared solutions and blanks, analyze sodium, potassium, calcium, and iron by graphite furnace atomic absorption (GFAA) and the remaining elements by inductively coupled plasma mass spectrometry (ICP/MS). For calibration, the standards are made up with the 1% nitric acid solution and the indium internal standard such that the final concentration is 20 ng/g of indium. Run a reagent blank.

10 Grade 3 Procedures

NOTE 6: The analytical procedures associated with this standard are not intended to be the only acceptable procedure or the best procedure available. The published procedures have been found to meet the required criteria for acceptance of an analytical procedure. Alternate procedures may be used if they meet the same criteria as the published procedures.

NOTE 7: Each laboratory is responsible for verifying the validity of each method within its own operation.

10.1 *Non-Metal Impurities*

10.1.1 See Section 8, which contains procedures for the following tests:

Assay

Color (APHA)

Free Acid

10.2 *TOC*

10.2.1 *Equipment*

10.2.1.1 TOC analyzer capable of analyzing total organic carbon in water.

10.2.1.2 Platinum sheet 1×1 inch, heated in a muffle oven at 800°C for 15 minutes.

10.2.2 *Special Reagents*

10.2.2.1 *Water* — The water used for all of the dilution, calibration, and standards should meet, at a minimum, the criteria for Type E1.1 in ASTM D 5127 in regard to TOC analysis.

10.2.2.2 *1000 µg/mL TOC Standard (prepare fresh weekly)* — Weigh accurately 0.2128 g of potassium acid phthalate into a 100 mL volumetric flask, add water, shake to dissolve, dilute to volume, and mix well. Lower standards (prepare fresh daily) can be made by diluting an aliquot of the 1000 µg/mL to the appropriate volume.

10.2.3 *Sample Preparation*

10.2.3.1 Weigh 50 g of hydrogen peroxide, to the nearest 0.01 g, into a 400 mL beaker. Add the platinum sheet to the sample, cover the beaker with a Teflon watch glass, and allow the reaction to go overnight (12 hours minimum). Transfer the solution to a 50 mL volumetric flask, dilute with water, meeting the criteria for Type E1.1 in ASTM D 5127 to a final volume of 50 mL.

10.2.4 *Analysis*

10.2.4.1 Using the prepared solutions, analyze TOC by the total organic carbon analyzer after the instrument has been calibrated with 0, 4, 10, and 20 µg/mL of TOC standards.

10.3 *Anions*

10.3.1 The following method has given satisfactory results in determining anion impurities at the values specified for each of the following anions: chloride (Cl), phosphate (PO_4), nitrate (NO_3), and sulfate (SO_4). Alternate methods may be used as long as appropriate studies demonstrate a recovery between 75–125% of a known sample spike for half of the value of each specified anion.

10.3.2 *Special Reagents*

10.3.2.1 *Eluent* — Prepare an eluent solution that is 2.2 mM sodium carbonate (Na_2CO_3) and 0.75 mM sodium bicarbonate ($NaHCO_3$) in deionized water meeting the criteria for Type E1.1 in ASTM D 5127. Store eluent under a helium gas blanket.

10.3.2.2 *Regenerant* — Prepare a 0.025 N sulfuric acid (H_2SO_4) in deionized water meeting the criteria for Type E1.1 in ASTM D 5127.

10.3.2.3 *Potassium Carbonate Solution* — Prepare a solution containing 500 mg of reagent grade potassium carbonate (K_2CO_3) in 100 mL of water meeting the criteria for Type E1.1 in ASTM D 5127.

10.3.3 *Sample Preparation*

10.3.3.1 In a clean environment, place 40 g of sample into a clean beaker. Add 1 mL of a 5 mg/mL potassium carbonate solution and evaporate carefully (at 100°C) to a volume of 0.5 mL. Dilute with water meeting the criteria for Type E1.1 in ASTM D 5127 to a final volume of 20 mL.

NOTE 8: For safety purposes, a decomposition aid such as a platinum strip should be used.

10.3.4 *Analysis*

10.3.4.1 Using the prepared solutions and blanks, analyze chloride, nitrate, phosphate, and sulfate by ion chromatography. Run a reagent blank. Samples and reagent blanks should be prepared and analyzed in triplicate.

10.3.4.2 *Columns* — Precolumn should be AG4-A (Dionex) or equivalent, and separation column should be AS4-A (Dionex) or equivalent.

10.4 *Trace Metals Analysis*

10.4.1 The following method has given satisfactory results in determining metal ion impurities at the values specified for each of the following metals: aluminum (Al), antimony (Sb), arsenic (As), boron (B), cadmium (Cd), calcium (Ca), chromium (Cr), cobalt (Co), copper (Cu), gold (Au), iron (Fe), lead (Pb), lithium (Li), magnesium (Mg), manganese (Mn), molybdenum (Mo), nickel (Ni), potassium (K), silver (Ag), sodium (Na), strontium (Sr), tin (Sn), titanium (Ti), vanadium (V), and zinc (Zn). Alternate methods may be used as long as appropriate studies demonstrate a recovery between 75–125% of a known sample spike for half of the value of each specified element.

10.4.2 *Special Reagents*

10.4.2.1 *Nitric Acid, Ultra Pure* — Use nitric acid specified for low metal ion content.

10.4.2.2 *1% Nitric Acid Solution* — Dilute 10 mL of ultrapure nitric acid to 1 L of water meeting the criteria for Type E1.1 in ASTM D 5127.

10.4.2.3 *Water* — The water used for all the dilution, calibration, and standards should meet, at a minimum, the criteria for Type E1.1 in ASTM D 5127 in regard to cation analysis.

10.4.2.4 *Indium Internal Standard* — Make up the indium internal standard solution to a concentration of 20 µg/mL (ppm) from the appropriate concentrated indium standard solution.

10.4.3 *Sample Preparation*

10.4.3.1 In a clean environment, place 20 g of sample into a tared FEP bottle and add 20 µL of the indium internal standard.

10.4.4 *Analysis*

10.4.4.1 Using the prepared solutions and blanks, analyze sodium, potassium, calcium, and iron by graphite furnace atomic absorption (GFAA) and the remaining elements by inductively coupled plasma mass spectrometry (ICP/MS). For calibration, the standards are made up with the 1% nitric acid solution and the indium internal standard such that the final concentration is 20 ng/g of indium. Run a reagent blank.

11 Grade 4 Procedures

NOTE 9: The analytical procedures associated with this standard are not intended to be the only acceptable procedure or the best procedure available. The published procedures have been found to meet the required criteria for acceptance of an analytical procedure. Alternate procedures may be used if they meet the same criteria as the published procedures.

NOTE 10: Each laboratory is responsible for verifying the validity of each method within its own operation.

11.1 *Non-Metal Impurities*

11.1.1 See Section 8, which contains procedures for the following tests:

Assay

11.2 *TOC*

11.2.1 *Equipment*

11.2.1.1 TOC analyzer capable of analyzing total oxidizable carbon in 31% H_2O_2. Validated instrumentation includes TOC analyzer using a high temperature platinum catalyst.

11.2.2 *Special Reagents*

11.2.2.1 *Water* — The water used for all of the dilutions, calibrations, and standards should be the appropriate grade of 18.2 Mohm-cm water that meets the criteria for Type E1.2 in ASTM D 5127.

11.2.2.2 *1000 µg/mL TOC Standard (prepare fresh weekly)* — Weigh accurately 0.2128 g of potassium acid phthalate into a 100 mL volumetric flask, add water, shake to dissolve, dilute to volume, and mix well. Lower standards (prepare fresh daily) can be made by diluting an aliquot of the 1000 µg/mL to the appropriate volume.

11.2.3 *Analysis*

11.2.3.1 Analyze TOC by directly injecting the 31% H_2O_2 into the total oxidizable carbon analyzer after the instrument has been calibrated with 0, 5, 10, and 30 µg/mL of TOC standards.

11.3 *Anions*

11.3.1 The following method has given satisfactory results in determining anion impurities at the values specified for each of the following anions: chloride (Cl), phosphate (PO_4), nitrate (NO_3), and sulfate (SO_4). Alternate methods may be used as long as validity is demonstrated as defined in SEMI C1, Section 3.14 (Method Validation).

11.3.2 *Special Reagents*

11.3.2.1 *Eluent* — Prepare an eluent solution that is 100 mM potassium hydroxide (KOH) in deionized water meeting the criteria for Type E1.2 in ASTM D 5127. Prepare second solution consisting of deionized water only meeting the criteria for Type E1.2 in ASTM D 5127. Store eluents under a helium gas blanket.

11.3.3 *Sample Preparation*

11.3.3.1 Prepare the following calibration standards by spiking 31% H_2O_2 with appropriate amounts of individual anion standards: 0, 5, 15, 30 ppb.

11.3.4 *Analysis*

11.3.4.1 *Gradient* — Using the prepared eluent solutions, design a gradient as follows, flow rate should remain 2ml/min throughout analysis:

Pump	*Time (min)*	*[mM KOH]*
isocratic	0.0–2.5	1.0
isocratic	2.5–14	9.0
ramp	14–15	40.0
ramp	15–30	47.0

11.3.4.2 *Columns* — Precolumn should be AG15 (Dionex) or equivalent, separation column should be AS15 (Dionex) or equivalent, concentrator column should be TAC-LP1 (Dionex) or equivalent.

11.3.4.3 Load 5mL standard then 5mL deionized water meeting the criteria for Type E1.2 in ASTM D 5127 onto concentrator column. Using the prepared solutions, blanks, and prescribed eluent gradient analyze chloride, nitrate, phosphate, and sulfate in neat 31% H_2O_2 by ion chromatography. Run a reagent blank. Samples and reagent blanks should be prepared and analyzed in triplicate.

11.4 *Trace Metals Analysis*

11.4.1 The following method has given satisfactory results in determining metal ion impurities at the values specified for each of the following metals: aluminum (Al), antimony (Sb), arsenic (As), barium (Ba), boron (B), cadmium (Cd), calcium (Ca), chromium (Cr), copper (Cu), iron (Fe), lead (Pb), lithium (Li), magnesium (Mg), manganese (Mn), nickel (Ni), potassium (K), sodium (Na), tin (Sn), titanium (Ti), vanadium (V), and zinc (Zn). Alternate methods may be used as long as validity is demonstrated as defined in SEMI C1, Section 3.14 (Method Validation).

11.4.2 *Special Reagents*

11.4.2.1 *Nitric Acid, Ultra Pure* — Use nitric acid specified for low metal ion content.

11.4.2.2 *1% Nitric Acid Solution* — Dilute 10 mL of ultrapure nitric acid to 1 L of water that meets the criteria for Type E1.2 in ASTM D 5127.

11.4.2.3 *Water* — The water used for all of the dilutions, calibrations, and standards should be the appropriate grade of 18.2 Mohm-cm water meeting the criteria for Type E1.2 in ASTM D 5127.

11.4.2.4 *Indium Internal Standard* — Make up the indium internal standard solution to a concentration of 20 µg/mL (ppm) from the appropriate concentrated indium standard solution.

11.4.3 *Sample Preparation*

11.4.3.1 In a clean environment, place 200 g of sample into a tared FEP bottle and add 20 µL of the indium internal standard.

11.4.4 *Analysis*

11.4.4.1 Using the prepared solutions and blanks, analyze the aforementioned metals by GFAA and/or inductively coupled plasma mass spectrometry (ICP-MS). For calibration, the standards are made up with the 1% nitric acid solution and the indium internal standard such that the final concentration is 2 ng/g of indium. Run a reagent blank.

12 Grade 5 Procedures

NOTE 11: The analytical procedures associated with this standard are not intended to be the only acceptable procedure or the best procedure available. The published procedures have been found to meet the required criteria for acceptance of an analytical procedure. Alternate procedures may be used if they meet the same criteria as the published procedures.

NOTE 12: Each laboratory is responsible for verifying the validity of each method within its own operation.

12.1 *Non-Metal Impurities*

12.1.1 See Section 8, which contains procedures for the following tests:

Assay

12.2 *TOC*

12.2.1 *Equipment*

12.2.1.1 TOC analyzer capable of analyzing total oxidizable carbon in 31% H_2O_2. Validated instrumentation includes TOC analyzer using a high temperature platinum catalyst.

12.2.2 *Special Reagents*

12.2.2.1 *Water* — The water used for all of the dilutions, calibrations, and standards should be the appropriate grade of 18.2 Mohm-cm water that meets the criteria for Type E1.2 in ASTM D 5127.

12.2.2.2 *1000 µg/mL TOC Standard (prepare fresh weekly)* — Weigh accurately 0.2128 g of potassium acid phthalate into a 100 mL volumetric flask, add water, shake to dissolve, dilute to volume, and mix well. Lower standards (prepare fresh daily) can be made by diluting an aliquot of the 1000 µg/mL to the appropriate volume.

12.2.3 *Analysis*

12.2.3.1 Analyze TOC by directly injecting the 31% H_2O_2 into the total oxidizable carbon analyzer after the instrument has been calibrated with 0, 5, 10, and 30 µg/mL of TOC standards.

12.3 *Anions*

12.3.1 The following method has given satisfactory results in determining anion impurities at the values specified for each of the following anions: chloride (Cl), phosphate (PO_4), nitrate (NO_3), and sulfate (SO_4). Alternate methods may be used as long as validity is demonstrated as defined in SEMI C1, Section 3.14 (Method Validation).

12.3.2 *Special Reagents*

12.3.2.1 *Eluent* — Prepare an eluent solution that is 100 mM potassium hydroxide (KOH) in deionized water meeting the criteria for Type E1.2 in ASTM D 5127. Prepare second solution consisting of deionized water only meeting the criteria for Type E1.2 in ASTM D 5127. Store eluents under a helium gas blanket.

12.3.3 *Sample Preparation*

12.3.3.1 Prepare the following calibration standards by spiking 31% H_2O_2 with appropriate amounts of individual anion standards: 0, 5, 15, 30 ppb.

12.3.4 *Analysis*

12.3.4.1 *Gradient* — Using the prepared eluent solutions, design a gradient as follows, flow rate should remain 2mL/min throughout analysis:

Pump	*Time (min)*	*[mM KOH]*
isocratic	0.0–2.5	1.0
isocratic	2.5–14	9.0
ramp	14–15	40.0
ramp	15–30	47.0

12.3.4.2 *Columns* — Precolumn should be AG15 (Dionex) or equivalent, separation column should be AS15 (Dionex) or equivalent, concentrator column should be TAC-LP1 (Dionex) or equivalent.

12.3.4.3 Load 5mL standard then 5mL deionized water meeting the criteria for Type E1.2 in ASTM D 5127 onto concentrator column. Using the prepared solutions, blanks, and prescribed eluent gradient analyze chloride, nitrate, phosphate, and sulfate in neat 31% H_2O_2 by ion chromatography. Run a reagent blank. Samples and reagent blanks should be prepared and analyzed in triplicate.

12.4 *Trace Metals Analysis*

12.4.1 The following method has given satisfactory results in determining metal ion impurities at the values specified for each of the following metals: aluminum (Al), antimony (Sb), arsenic (As), barium (Ba), boron (B), cadmium (Cd), calcium (Ca), chromium (Cr), copper (Cu), iron (Fe), lead (Pb), lithium (Li), magnesium (Mg), manganese (Mn), nickel (Ni), potassium (K), sodium (Na), tin (Sn), titanium (Ti), vanadium (V), and zinc (Zn). Alternate methods may be used as long as validity is demonstrated as defined in SEMI C1, Specifications for Reagents; Section 3.14, Method Validation.

12.4.2 *Special Reagents*

12.4.2.1 *Nitric Acid, Ultra Pure* — Use nitric acid specified for low metal ion content.

12.4.2.2 *1% Nitric Acid Solution* — Dilute 10 mL of ultrapure nitric acid to 1 L of water meeting the criteria for Type E1.2 in ASTM D 5127.

12.4.2.3 *Water* — The water used for all of the dilutions, calibrations, and standards should be the appropriate grade of 18.2 Mohm-cm water that meets the criteria for Type E1.2 in ASTM D 5127.

12.4.2.4 *Indium Internal Standard* — Make up the indium internal standard solution to a concentration of 20 µg/mL (ppm) from the appropriate concentrated indium standard solution.

12.4.3 *Sample Preparation*

12.4.3.1 In a clean environment, place 200 g of sample into a tared FEP bottle and add 20 µL of the indium internal standard.

12.4.4 *Analysis*

12.4.4.1 Using the prepared solutions and blanks, analyze the aforementioned metals by GFAA and/or inductively coupled plasma mass spectrometry (ICP-MS). For calibration, the standards are made up with the 1% nitric acid solution and the indium internal standard such that the final concentration is 2 ng/g of indium. Run a reagent blank.

13 VLSI Grade Procedures

13.1 Specific procedures for this grade do not exist. Refer to Sections 8 and 9 for available procedures.

14 Tier A Procedures

14.1 This section does not apply to this chemical.

15 Tier B Procedures

15.1 This section does not apply to this chemical.

16 Tier C Procedures

16.1 This section does not apply to this chemical.

17 Tier D Procedures

17.1 This section does not apply to this chemical.

NOTE 1: Care must be taken in analyzing particles because of the potential formation of microbubbles.
NOTE 2: Due to the limitations of current particle counters, particle size and number are to be agreed upon between supplier and user. See SEMI C1, Section 3.9 for particle counting methodology.

SEMI C31-0301
SPECIFICATION FOR METHANOL

This specification was technically approved by the Global Process Chemicals Committee and is the direct responsibility of the North American Process Chemicals Committee. Current edition approved by the North American Regional Standards Committee on October 17, 1999. Initially available at www.semi.org February 2001; to be published March 2001. This document replaces SEMI C1.10 in its entirety. Originally published in 1978; previously published June 1999.

1 Purpose

1.1 The purpose of this document is to standardize requirements for methanol used in the semiconductor industry and testing procedures to support those standards. Test methods have been shown to give statistically valid results. This document also provides guidelines for grades of methanol for which a need has been identified. In the case of the guidelines, the test methods may not have been statistically validated yet.

2 Scope

2.1 The scope of this document is all grades of methanol used in the semiconductor industry.

2.2 These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 None.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI C1 — Specifications for Reagents

4.2 *ASTM Standards*[1]

ASTM D5127 — Standard Guide for Ultra Pure Water Used in the Electronics and Semiconductor Industry

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 None.

6 Physical Property (for information only)

Density at 25°C	0.79 g/mL
Boiling Point	64.5°C

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, Pennsylvania 19428-2959, USA. Telephone: 610.832.9585, Fax: 610.832.9555. Website: www.astm.org

7 Requirements

7.1 The requirements for methanol for Grade 1 are listed in Table 1.

8 Grade 1 Procedures

NOTE 2: Each laboratory is responsible for verifying the validity of the method within its own operation.

8.1 *Assay* — Analyze the sample by gas chromatography (see SEMI C1, Section 3.1, Guidelines for Assay by Wide Bore Column Gas Chromatography). The parameters cited have given satisfactory results.

Column: 30 meter × 530 micron I.D. fused silica capillary, coated with 5 micron film of DB-1 or equivalent (100% methyl silicone which has been surface bonded and cross linked).

Column Temperature: 40°C isothermal for 5 minutes, then programmed to 200°C at 10°C/min.

Injector Temperature:	150°C
Detector Temperature:	250°C
Sample Size:	0.2 µL splitless
Carrier Gas:	Helium at 3 mL/min
Detector:	Thermal Conductivity
Approximate Retention Times (min):	
Methanol	3.0
Ethanol	4.0
Acetone	4.8

8.2 *Color* — Dilute 2.0 mL of platinum-cobalt stock solution (APHA No. 500) to 100 mL with water. Compare this standard (APHA No. 10) with 100 mL of sample in Nessler tubes. View vertically over a white background. The sample must be no darker than the standard.

8.3 *Acidity* — To 25 mL of water in a glass-stoppered flask, add 10 mL of sample and 0.1 mL of phenolphthalein indicator solution. Add 0.01 N sodium hydroxide until a slight pink color persists after shaking for one-half minute. Add 42 mL (33 g) of the sample, mix well, and titrate with 0.01 N sodium hydroxide until the pink color is reproduced. Not more than 1.0

mL of the sodium hydroxide solution should be required.

8.4 *Alkalinity* — Add 126 mL (100 g) of sample to 25 mL of water and mix well. Add 0.05 mL of methyl red indicator solution. Titrate with 0.01 N hydrochloric acid until a slight pink color is produced. Not more than 1.0 mL of the hydrochloric acid should be required.

8.5 *Residue after Evaporation* — Evaporate 253 mL (200 g) of sample to dryness. Dry at 105°C for 30 minutes, cool in a desiccator, and weigh (see SEMI C1, Section 3.3, Determination of Residue After Evaporation).

8.6 *Water* — Add 50 mL of sample to a dry titration flask and add Karl Fischer (KF) reagent to a visually or electrometrically determined endpoint that persists for 30 seconds. Add 50 mL (40 g) of sample, taking care to protect the sample and contents of the flask from moisture. Stir vigorously and titrate with Karl Fischer reagent to the same endpoint.

$$\% \text{ Water } (H_2O) = \frac{\text{mL KF reagent} \times \text{KF factor } (\text{g } H_2O/\text{mL}) \times 100}{\text{Weight of sample (g)}}$$

8.7 *Solubility in Water* — Mix 15 mL of sample with 45 mL of water. Allow to stand for 30 minutes. The solution should be as clear as an equal volume of water.

8.8 *Boron* — To 127 mL (100 g) of sample, add 0.10 mL of 10% sodium hydroxide solution, and evaporate to dryness in a nitrogen atmosphere using a covered chamber such as a Thiers assembly (or equivalent). Dissolve the residue with 2 mL of water and 0.10 mL of hydrochloric acid. Transfer to a test tube, cool in an ice bath, and add 10 mL of sulfuric acid. Then add 10 mL of carminic acid solution and remove from the ice bath. Allow to stand for 45 minutes. Prepare a standard containing 0.001 mg of boron treated exactly as the sample. Run a complete blank determination on 2 mL of water. Measure the absorbances of the sample and standard against the blank at 585 nm using 5.00 cm cells. The absorbance of the sample solution should be no greater than that of the standard.

8.9 *Chloride* — To 63 mL (50 g) of sample, add 10 mL of sodium carbonate reagent solution and evaporate to dryness on a steam bath in a hood. Dissolve the residue in 10 mL of water. Add 1 mL of nitric acid and dilute to 20 mL with water. Add 1 mL of silver nitrate reagent solution. Any turbidity produced should be no greater than that produced when 0.01 mg of chloride ion (Cl) is treated as the sample.

8.10 *Phosphate* — To 25 mL (20 g) of sample add 10 mL of sodium carbonate reagent solution and evaporate to dryness on a steam bath in a hood. Dissolve the residue in 25 mL of 0.5 N sulfuric acid. Add 1 mL of ammonium molybdate reagent solution and 1 mL of p-(methylamino)phenol sulfate reagent solution. Allow to stand at room temperature for 2 hours. Any blue color produced should be no greater than that produced when 0.01 mg of phosphate ion (PO_4) is treated as the sample.

8.11 *Arsenic and Antimony (as As)* — Evaporate 253 mL (200 g) of sample in a 400 mL beaker to a small volume in a hood. Add 50 mL of water and again evaporate to a small volume. Repeat the evaporation with water addition. Do not allow to go to dryness. Add 5 mL of nitric acid and 5 mL of sulfuric acid and evaporate to dense fumes of sulfur trioxide. Cool, cautiously add 10 mL of water, and again evaporate to dense fumes of sulfur trioxide. Cool, and cautiously wash into a generator flask with water to make a volume of 35 mL. Proceed as described in the General Method for Arsenic (and Antimony) under SEMI C1, Section 3.4.5, starting with the sentence which begins: "Swirl the flask...." Any red color in the silver diethyldithiocarbamate solution from the sample should be no greater than that of the standard containing 0.002 mg of arsenic (As).

8.12 *Trace Metal Analysis*

8.12.1 *Gold (Au)* — Analyze by graphite atomic absorption using the manufacturer's recommended procedure. This technique has been shown to give satisfactory results using a 1:4 dilution and Zeeman background correction. Each laboratory must determine the appropriate dilution and background correction for its instrument to meet the specification limit.

8.12.2 The following method has given satisfactory results in determining trace metal impurities at the value specified for each of the following trace metals: aluminum (Al), calcium (Ca), chromium (Cr), copper (Cu), iron (Fe), lead (Pb), magnesium (Mg), manganese (Mn), nickel (Ni), potassium (K), sodium (Na), tin (Sn), titanium (Ti), and zinc (Zn). Alternate methods may be used as long as appropriate studies demonstrate recovery between 75 - 125% of a known sample spike for half of the value of each specified item.

8.12.3 *Special Reagents*

8.12.3.1 *Hydrochloric Acid, Ultra Pure* — Use hydrochloric acid specified for ultra low metal ion content.

8.12.3.2 *2% (v/v) Hydrochloric Acid Solution* — Dilute 20 mL of ultra pure 12 M hydrochloric acid to 1 L using water meeting the criteria for Type E1 in ASTM D5127.

8.12.4 *Sample Preparation*

8.12.4.1 In a clean environment, place 250 g of solvent in a PTFE dish. Slowly evaporate on a hot plate avoiding loss of sample by effervescence or spattering until approximately 1 mL of liquid remains. Take up liquid and all visible residue (from walls of dish) with 1 mL ultra pure, 12 M hydrochloric acid and continue heating until approximately 0.5 mL of liquid remains. No undissolved particulate matter should be observed. Otherwise repeat the addition of hydrochloric acid until all particulate matter is dissolved. Transfer quantitatively to a 50 mL volumetric flask using 2% (v/v) hydrochloric acid and adjust liquid level to mark. Prepare a reagent blank using the same reagents and in the same manner as for the sample concentration.

8.12.5 *Analysis*

8.12.5.1 Using the prepared sample and reagent blank, analyze group I elements potassium (K) and sodium (Na) by atomic absorption spectroscopy and all other elements by plasma emission spectroscopy. Apply, if necessary, a reagent blank correction to the final determined value of the sample.

NOTE 3: Due to the uncertainty of acid concentration in the liquid residue the final concentration can be estimated to be approximately 2% (v/v). Standard calibration solutions are to use this same acid concentration.

SEMI

SEMI C32-0699
SPECIFICATION FOR METHYL ETHYL KETONE

This specification was technically approved by the Global Process Chemicals Committee and is the direct responsibility of the North American Process Chemicals Committee. Current edition approved by the North American Regional Standards Committee on April 23, 1999. Initially available on SEMI OnLine May 1999; to be published June 1999. This document replaces SEMI C1.11 in its entirety. Originally published in 1978.

1 Purpose

1.1 The purpose of this document is to standardize requirements for methyl ethyl ketone used in the semiconductor industry and testing procedures to support those standards. Test methods have been shown to give statistically valid results. This document also provides guidelines for grades of methyl ethyl ketone for which a need has been identified. In the case of the guidelines, the test methods may not have been statistically validated yet.

2 Scope

2.1 The scope of this document is all grades of methyl ethyl ketone used in the semiconductor industry.

3 Limitations

3.1 None.

4 Referenced Documents

SEMI C1 — Specifications for Reagents

5 Terminology

5.1 None.

6 Physical Property (for information only)

Density at 25°C	0.80 g/mL
Boiling Point	79.6°C

7 Requirements

7.1 The requirements for methyl ethyl ketone for Grade 1 are listed in Table 1.

8 Grade 1 Procedures

8.1 *Assay* — Analyze the sample by gas chromatography (see SEMI C1, Section 3.1, Guidelines for Assay by Wide Bore Column Gas Chromatography). The parameters cited have given satisfactory results.

Column: 30 meter × 530 micron I.D. fused silica capillary, coated with 5 micron film of DB-1 or equivalent (100% methyl silicone which has been surface bonded and cross linked).

Column Temperature: 40°C isothermal for 5 minutes, then programmed to 200°C at 10°C/min.

Injector Temperature:	150°C
Detector Temperature:	250°C
Sample Size:	0.2 µL splitless
Carrier Gas:	Helium at 3 mL/min
Detector:	Thermal Conductivity
Approximate Retention Times (min):	
Methyl Ethyl Ketone	9.0
2-Butanol	10.5

8.2 *Color* — Dilute 3.0 mL of platinum-cobalt stock solution (APHA No. 500) to 100 mL with water. Compare this standard (APHA No. 15) with 100 mL of sample in Nessler tubes. View vertically over a white background. The sample must be no darker than the standard.

8.3 *Acidity* — To 25 mL of water in a glass-stoppered flask, add 10 mL of sample and 0.1 mL of phenolphthalein indicator solution. Add 0.10 N sodium hydroxide until a slight, pink color persists after shaking for one-half minute. Add 21 mL (17 g) of the sample, mix well, and titrate with 0.01 N sodium hydroxide until the pink color is reproduced. Not more than 3.0 mL of the sodium hydroxide solution should be required.

8.4 *Residue After Evaporation* — Evaporate 63 mL (50 g) of sample to dryness. Dry at 105°C for 30 minutes, cool in a desiccator, and weigh (see SEMI C1, Section 3.3, Determination of Residue After Evaporation).

8.5 *Water* — Add 25 mL of pyridine-dichloromethane mixture (1 + 1) to a dry titration flask and add Karl Fischer (KF) reagent to a visually or electrometrically determined endpoint that persists for 30 seconds. Add 25 mL (20 g) of sample, taking care to protect the sample and contents of the flask from moisture. Stir vigorously and titrate with Karl Fischer reagent to the same endpoint.

$$\%\ \text{Water}\ (H_2O) = \frac{\text{mL KF reagent} \times \text{KF factor}\ (\text{g}\ H_2O/\text{mL}) \times 100}{\text{Weight of sample (g)}}$$

8.6 *Phosphate* — To 12.5 mL (10 g) of sample, add 10 mL of sodium carbonate reagent solution and evaporate to dryness on a steam bath in a hood. Carefully dissolve the residue in 25 mL of 0.5 N sulfuric acid. Add 1 mL of ammonium molybdate reagent solution and 1 mL of p-(methylamino)phenol sufate reagent solution. Allow to stand at room temperature for 2 hours. Any blue color should be no greater than that produced when 0.01 mg of phosphate ion (PO_4) is treated as the sample.

8.7 *Heavy Metals (as Pb)* — Evaporate 25 mL (20 g) of sample to dryness on a steam bath in a hood. Dissolve the residue in 3 mL of dilute hydrochIoric acid (1 + 1) and dilute with water to 15 mL. If necessary, filter through a small filter, and wash the evaporating dish and the filter with 10 mL of water. Dilute to 25 mL with water. For the standard, dilute a solution containing 0.02 mg of lead ion (Pb) and 3 mL of dilute hydrochloric acid (1 + 1) to 25 mL with water. Adjust the pH of both solutions to between 3 and 4 with dilute ammonium hydroxide (10% NH_3) or with acetic acid, and dilute with water to 40 mL. To each solution, add 10 mL of freshly prepared hydrogen sulfide water and compare. The sample solution should be no darker than the standard.

8.8 *Arsenic and Antimony (as As)* — Evaporate 250 mL (200 g) of sample in a 400 mL beaker to a small volume in a hood. Add 50 mL of water and again evaporate to a small volume. Repeat the evaporation with water addition. Do not allow to go to dryness. Add 5 mL of nitric acid and 5 mL of sulfuric acid and evaporate to dense fumes of sulfur trioxide. Cool and cautiously add 10 mL of water, and again evaporate to dense fumes of sulfur trioxide. Cool and cautiously wash into a generator flask with water to make a volume of 35 mL. Proceed as described in the General Method for Arsenic (and Antimony) under SEMI C1, Section 3.4.5, starting with the sentence which begins, "Swirl the flask...." Any red color in the silver diethyldithiocarbamate solution of the sample should be no greater than that of the standard containing 0.002 mg of arsenic (As).

8.9 *Trace Element Contents* — By a suitable emission spectrographic procedure, determine for each of the specified trace elements that its content is not greater than the stated specification limit (see SEMI C1, Section 3.5, Guidelines for Determination of Trace Elements by Emission Spectrography).

Zinc (Zn)	1 ppm max

SEMI C33-0301
SPECIFICATIONS FOR n-METHYL 2-PYRROLIDONE

These specifications were technically approved by the Global Process Chemicals Committee and are the direct responsibility of the North American Process Chemicals Committee. Current edition approved by the North American Regional Standards Committee on October 17, 1999. Initially available at www.semi.org February 2001; to be published March 2001. This document replaces SEMI C1.25, C7.16, and C8.11 in their entirety. Originally published in 1986, 1992, and 1998 respectively; previously published June 1999.

1 Purpose

1.1 The purpose of this document is to standardize requirements for n-methyl 2-pyrrolidone used in the semiconductor industry and testing procedures to support those standards. Test methods have been shown to give statistically valid results. This document also provides guidelines for grades of n-methyl 2-pyrrolidone for which a need has been identified. In the case of the guidelines, the test methods may not have been statistically validated yet.

2 Scope

2.1 The scope of this document is all grades of n-methyl 2-pyrrolidone used in the semiconductor industry.

2.2 These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 None.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI C1 — Specifications for Reagents

4.2 *ASTM Standards*[1]

ASTM D5127 — Standard Guide for Ultra Pure Water Used in the Electronics and Semiconductor Industry

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 None.

6 Physical Property (for information only)

Density at 25°C	1.03 g/mL

7 Requirements

7.1 The requirements for n-methyl 2-pyrrolidone for Grades 1, 2, and 3 are listed in Table 1.

8 Grade 1 Procedures

NOTE 2: Due to the uncertainty of acid concentration in the liquid residue, the final concentration can be estimated to be approximately 2% (v/v).

NOTE 3: Each laboratory is responsible for verifying the validity of the method within its own operation.

8.1 *Assay* — Analyze the sample by gas chromatography (see SEMI C1, Section 3.1, Guidelines for Assay by Wide Bore Column Gas Chromatography). The parameters cited have given satisfactory results.

Column: 30 × 530 micron I.D. fused silica capillary, coated with 5 micron film of DB-1 or equivalent (100% methyl silicone which has been surface bonded and cross linked).

Column Temperature:	100°C isothermal
Injector Temperature:	250°C
Detector Temperature:	300°C
Sample Size:	0.2 µL splitless
Carrier Gas:	Helium at 5 mL/min
Detector:	Thermal Conductivity
Approximate Retention Times (min):	
Butyrolactone	15.2
1-Methyl 2-Pyrrolidone	20.2
Methyl Homologue	21.2
Methyl Homologue	23.0

8.2 *Color* — Dilute 10.0 mL of platinum-cobalt stock solution (APHA No. 500) with water. Compare this standard (APHA No. 50) with 100 mL of sample in Nessler tubes. View vertically over a white background. The sample must be no darker than the standard.

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, Pennsylvania 19428-2959, USA. Telephone: 610.832.9585, Fax: 610.832.9555. Website: www.astm.org

8.3 *Water* — Add 25 mL of methanol to a dry titration flask and add Karl Fischer (KF) reagent to a visually or electrometrically determined endpoint that persists for 30 seconds. Add 98 mL (100 g) of sample, taking care to protect the sample and contents of the flask from moisture. Stir vigorously and titrate with Karl Fischer reagent to the same endpoint.

$$\% \text{ Water } (H_2O) = \frac{\text{mL KF reagent} \times \text{KF factor} (\text{g } H_2O/\text{mL}) \times 100}{\text{Weight of sample (g)}}$$

8.4 *Free Amines* — Weigh 63 mL (65 g) of sample into a 500 mL beaker. Add 100 mL of 2-propanol and mix thoroughly. Into the solution, insert a pH and reference electrodes connected to a pH meter set to the direct voltage mode. Titrate potentiometrically with 0.05 N hydrochloric acid in 2-propanol. Express the result in terms of methylamine:

$$\% \text{ Free Amines as } (CH_3NH_2) = \frac{\text{mL} \times \text{N of HCl} \times 3.10}{\text{Weight of sample (g)}}$$

8.5 *Chloride* — In a 50 mL glass-stoppered graduated cylinder, dilute 24.5 mL (25 g) of sample with water to volume. Place a 10 mL aliquot of this solution into a 50 mL Nessler tube and a 30 mL aliquot into a second tube. To the first tube add 0.01 mg of chloride standard and mix. Dilute the contents of each tube to about 45 mL with water, mix, add 1 mL of nitric acid and 1 mL of silver nitrate reagent solution, mix thoroughly, and allow to stand for 10 minutes. Any turbidity produced by the sample should be no greater than that of the 0.01 mg standard.

8.6 *Phosphate* — Add 20 mL (20) of sample to 100 mL of dilute ammonium hydroxide (1 + 4). Prepare a standard containing 0.1 mg of phosphate ion (PO_4) in 100 mL of dilute ammonium hydroxide. Proceed as follows with each of the two solutions.

8.6.1 Add, while stirring vigorously, 3.5 mL of a 10% solution of ferric nitrate 9-hydrate. Allow to stand for 15 minutes. If the precipitate has not coagulated by this time, warm gently (avoid boiling). Filter and wash the precipitate on the filter with several portions of quite dilute ammonium hydroxide (1 + 9). Discard the filtrate and washings. Dissolve the precipitate on the filter with 50 mL nitric acid (1 + 3) added in small portions. Catch the filtrate in a 250 mL glass-stoppered conical flask. Add 13 mL of ammonium hydroxide (28-32% NH_3) to the flask while swirling and continue agitation until any precipitate redissolves. Warm the solution to 40°C and add 50 mL of ammonium molybdate-nitric acid reagent solution. Shake vigorously for 5 minutes and allow to stand at 40°C for 2 hours. The precipitate, if any, for the sample should be no greater than that for the standard.

8.6.2 *Ammonium Molybdate-Nitric Acid Reagent Solution* — Mix thoroughly 100 g of molybdate acid, 85%, with 240 mL of water and 140 mL of ammonium hydroxide (28 - 32% NH_3). Filter and add 60 mL of nitric acid. Cool and while stirring continually, pour into a cooled mixture of 400 mL of nitric acid and 960 mL of water. Add 0.1 g of ammonium phosphate, monobasic, $NH_4H_2PO_4$, allow to stand 24 hours and filter through glass wool.

8.7 *Arsenic and Antimony (as As)* — Evaporate 20 mL (20 g) of sample in a 150 mL beaker to a small volume on a hot plate. Cool, add carefully 15 mL of nitric acid and 5 mL of sulfuric acid, and evaporate to dense fumes of sulfur trioxide. Add 10 mL of nitric acid and again evaporate to dense fumes. If carbon is still present, cool, add 1 mL of 30% hydrogen peroxide, and evaporate to dense fumes of sulfur trioxide. Repeat this step with hydrogen peroxide addition until carbon has been removed completely. Cool, and cautiously wash the colorless residue into a generator flask with water to make a volume of 35 mL. Proceed as described in the General Method for Arsenic (and Antimony) under SEMI C1, Section 3.4.5, starting with the sentence that begins "Swirl the flask...". Any red color in the silver diethyldithiocarbamate solution of the sample should be no greater than that of the standard containing 0.002 mg of arsenic (As).

8.8 *Trace Metal Analysis* — The following method has given satisfactory results in determining trace metal impurities at the value specified for each of the following trace metals: aluminum (Al), boron (B), calcium (Ca), chromium (Cr), copper (Cu), gold (Au), iron (Fe), lead (Pb), magnesium (Mg), manganese (Mn), nickel (Ni), potassium (K), sodium (Na), tin (Sn), titanium (Ti), and zinc (Zn). Alternate methods may be used as long as appropriate studies demonstrate recovery between 75–125% of a known sample spike for half of the value of each specified item.

8.8.1 *Special Reagents*

8.8.1.1 *Hydrochloric Acid, Ultra Pure* — Use hydrochloric acid specified for ultra low metal ion content.

8.8.1.2 *Mannitol Powder* — Use mannitol specified for reagent grade (A.C.S.) and determined, via the reagent blank, to be ultra metal ion content.

8.8.1.3 *5% Mannitol Solution* — Dissolve and dilute 5 g of mannitol to 100 mL using water meeting the criteria for Type E1.1 in ASTM D5127.

8.8.1.4 *2% (v/v) Hydrochloric Acid Solution* — Dilute 20 mL of ultra pure, 12 M hydrochloric acid to 1 L using water meeting the criteria for Type E1.1 in ASTM D5127.

8.8.2 *Sample Preparation*

8.8.2.1 In a clean environment, place 250 g of solvent in a PTFE dish. Add 0.5 mL of freshly prepared 5% mannitol solution. Slowly evaporate on a hot plate, avoiding loss of sample by effervescence or spattering until approximately 1 mL of liquid remains. Take up liquid and all visible residue (from walls of dish) with 1 mL ultra pure, 12 M hydrochloric acid and continue heating until approximately 0.5 mL of liquid remains. No undissolved particulate matter should be observed. Otherwise, repeat the addition of hydrochloric acid until all particulate matter is dissolved. Transfer quantitatively to a 50 mL volumetric flask using 2% (v/v) hydrochloric acid and adjust liquid level to mark. Prepare a reagent blank using the same reagents and in the same manner as for the sample concentration.

8.8.3 *Analysis*

8.8.3.1 Using the prepared sample and reagent blank, analyze group 1 elements potassium (K) and sodium (Na) by atomic absorption spectroscopy and all other elements by plasma emission spectrometry. Apply, if necessary, a reagent blank correction to the final determined value of the sample.

9 Grade 2 Procedures

9.1 *Non-Metal Impurities* — See Section 8, which contains procedures for the following tests:

Assay

Color (APHA)

Water (H_2O)

9.2 *Methyl Amines*

9.2.1 The following method has given satisfactory results in determining methyl amine impurities at the values specified for each of the following methyl amines: mono-methylamine (MMA), di-methylamine (DMA), and tri-methylamine (TMA). Alternative methods may be used as long as appropriate studies demonstrate a recovery between 75 - 125% of a known sample spike for half of the value of each specified element.

9.2.2 *Special Reagents*

9.2.2.1 *Eluent* — Prepare 0.025 N hydrochloric (HCl) solution in deionized water meeting the criteria for Type E1.1 in ASTM D5127.

9.2.2.2 *Regenerant* — Prepare a 0.1 M tetrabutyl-ammonium hydroxide (TBAOH) solution in deionized water meeting the criteria for Type E1.1 in ASTM D5127.

9.2.3 *Sample Preparation* — Sample is injected neat.

9.2.4 *Analysis*

9.2.4.1 Using the prepared solutions and blanks, analyze mono-methylamine, di-methylamine, and tri-methylamine by ion chromatography. Run a reagent blank. Samples and reagent blanks should be prepared and analyzed in triplicate.

9.2.4.2 *Columns* — Precolumn should be CG2 (Dionex) or equivalent and separation column should be a CS2 (Dionex) or equivalent.

9.3 *Anions*

9.3.1 The following method has given satisfactory results in determining various anions at the values specified for each of the following anions: chloride (Cl), nitrate (NO_3), phosphate (PO_4), and sulfate (SO_4). Alternate methods may be used as long as appropriate studies demonstrate a recovery between 75–125% of a known sample spike for half of the value of each specified anion.

9.3.2 *Special Reagents*

9.3.2.1 *Eluent* — Prepare a solution containing 0.38 g of sodium carbonate (Na_2CO_3) and 0.29 g of sodium bicarbonate ($NaHCO_3$) in 2 liters of deionized water meeting the criteria for Type E1.1 in ASTM D5127.

9.3.2.2 *Regenerant* — Deionized water meeting the criteria for Type E1.1 in ASTM D5127.

9.3.3 *Sample Preparation*

9.3.3.1 20 mL of NMP is added to a 100 mL plastic volumetric flask and is filled to the mark using deionized water meeting the criteria for Type E1.1 in ASTM D5127.

9.4 *Analysis*

9.4.1 Using the prepared solutions and blanks, analyze chloride, nitrate, phosphate, and sulfate by ion chromatography. Run a reagent blank. Samples and blanks should be prepared in triplicate.

9.4.2 *Columns* — Precolumn should be AG3 (Dionex) or equivalent and the separation column should be AS3 (Dionex) or equivalent.

9.5 *Trace Metals Analysis*

9.5.1 The following method has given satisfactory results in determining metal ion impurities at the values specified for each of the following metals: aluminum (Al), antimony (Sb), arsenic (As), boron (B), cadmium (Cd), calcium (Ca), chromium (Cr), cobalt (Co), copper (Cu), gold (Au), iron (Fe), lead (Pb), lithium (Li), magnesium (Mg), manganese (Mn), nickel (Ni), potassium (K), silver (Ag), sodium (Na), strontium (Sr), tin (Sn), titanium (Ti), vanadium (V), and zinc (Zn). Alternate methods may be used as long as appropriate studies demonstrate a recovery between 75 - 125% of a known sample spike for half of the value of each specified element.

9.5.2 *Special Reagents*

9.5.2.1 *Nitric Acid, Ultra Pure* — Use nitric acid specified for low metal ion content.

9.5.2.2 *Water* — The water used for all the dilution, calibration, and standards should meet, at a minimum, the criteria for Type E1.1 in ASTM D5127 in regard to cation analysis.

9.5.2.3 *Indium Internal Standard* — Make up the indium internal standard solution to a concentration of 20 µg/mL (ppm) from the appropriate concentrated indium standard solution.

9.5.3 *Sample Preparation*

9.5.3.1 Place sample (1 gram) in a quartz dish. Slowly evaporate to dryness (45 min. at 70–80°C). Add 2 grams of concentrated nitric acid and heat for 15 miutes until approximately 1 gram remains. Remove the hotplate and add DI water to a final weight of 10 grams.

9.5.4 *Analysis*

9.5.4.1 Using the prepared solution and blanks, analyze the elements by inductively coupled plasma mass spectrometry (ICP/MS). For calibration, the standards are made up with 1% nitric acid solution and the indium internal standard such that the final indium concentration is 20 ng/g.

10 Grade 3 Procedures

10.1 *Non-Metal Impurities* — See Section 8, which contains procedures for the following tests:

Assay

Color (APHA)

Water (H_2O)

10.2 *Methyl Amines*

10.2.1 The following method has given satisfactory results in determining methyl amine impurities at the values specified for each of the following methyl amines: mono-methylamine (MMA), dimethylamine (DMA), and trimethylamine (TMA). Alternative methods may be used as long as appropriate studies demonstrate a recovery between 75 - 125% of a known sample spike for half of the value of each specified element.

10.2.2 *Special Reagents*

10.2.2.1 *Eluent* — Prepare 0.025 N hydrochloric acid (HCl) solution in deionized water meeting the criteria for Type E1.1 in ASTM D5127.

10.2.2.2 *Regenerant* — Prepare a 0.1 M tetrabutyl-ammonium hydroxide (TBAOH) solution in deionized water meeting the criteria for Type E1.1 in ASTM D5127.

10.2.3 *Sample Preparation* — Sample is injected neat.

10.2.4 *Analysis*

10.2.4.1 Using the prepared solutions and blanks, analyze mono-methylamine, di-methylamine, and tri-methylamine by ion chromatography. Run a reagent blank. Samples and reagent blanks should be prepared and analyzed in triplicate.

10.2.4.2 *Columns* — Pre-column should be CG2 (Dionex) or equivalent and separation column should be a CS2 (Dionex) or equivalent.

10.3 *Anions*

10.3.1 The following method has given satisfactory results in determining various anions at the values specified for each of the following anions: chloride (Cl), nitrate (NO_3) phosphate (PO_4) and sulfate (SO_4). Alternate methods may be used as long as appropriate studies demonstrate a recovery between 75–125% of a known sample spike for half of the value of each specified anion.

10.3.2 *Special Reagents*

10.3.2.1 *Eluent* — Prepare a solution containing 0.38 g of sodium carbonate (Na_2CO_3) and 0.29 g of sodium bicarbonate ($NaHCO_3$) in 2 liters of deionized water meeting the criteria for Type E1.1 in ASTM D5127.

10.3.2.2 *Regenerant* — Deionized water meeting the criteria for Type E1.1 in ASTM D5127.

10.3.3 *Sample Preparation*

10.3.3.1 20 mL of NMP is added to a 100 mL plastic volumetric flask and is filled to the mark using deionized water meeting the criteria for Type E1.1 in ASTM D5127.

10.3.4 *Analysis*

10.3.4.1 Using the prepared solutions and blanks, analyze chloride, nitrate, phosphate, and sulfate by ion chromatography. Run a reagent blank. Samples and blanks should be prepared in triplicate.

10.3.4.2 *Columns* — Pre-column should be AG3 (Dionex) or equivalent and the separation column should be AS3 (Dionex) or equivalent.

10.4 *Trace Metal Analysis*

10.4.1 The following method has given satisfactory results in determining metal ion impurities at the values specified for each of the following metals: aluminum (Al), antimony (Sb), arsenic (As), boron (B), calcium (Ca), chromium (Cr), copper (Cu), gold (Au), iron (Fe), lead (Pb), magnesium (Mg), manganese (Mn), nickel (Ni), potassium (K), sodium (Na), tin (Sn), titanium (Ti), and zinc (Zn). Alternate methods may be used as long as appropriate studies demonstrate a recovery between 75–125% of a known sample spike for half of the value of each specified element.

10.4.2 *Special Reagents*

10.4.2.1 *Nitric Acid, Ultra Pure* — Use nitric acid specified for low metal ion content.

10.4.2.2 *Water* — The water used for all the dilution, calibration, and standards should meet, at a minimum, the criteria for Type E1.1 in ASTM D5127 in regard to cation analysis.

10.4.3 *Sample Preparation*

10.4.3.1 In a 100 mL volumetric, add 20 mL of sample and fill to the mark such that the final solution contains 2% nitric acid.

10.4.4 *Standard Preparation*

10.4.4.1 Four standards are prepared such that the final solution contains 2% nitric acid (i.e., 2% of 70% nitric acid vol/vol) and 20% vol/vol sample. The four standards are 0.5, 1, 5, and 10 ppb.

10.4.5 *Analysis*

10.4.5.1 This is a method of standard addition procedure. Using the prepared solutions, analyze the elements by inductively coupled plasma mass spectrometry (ICP/MS).

10.4.5.2 Hot plasma conditions with shield are used for the following elements: Ti, Mn, Ni, Cu, As, Sb, Sn, Au, and Pb.

10.4.5.3 Cold plasma conditions with shield are used for the follow elements, B, Na, Mg, Al, K, Ca, Cr, Fe, and Zn.

11 Grade 4 Procedures

NOTICE: SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI C34-0699
SPECIFICATION AND GUIDELINE FOR MIXED ACID ETCHANTS

This specification and this guideline were technically approved by the Global Process Chemicals Committee and are the direct responsibility of the North American Process Chemicals Committee. Current edition approved by the North American Regional Standards Committee on April 23, 1999. Initially available on SEMI OnLine May 1999; to be published June 1999. This document replaces SEMI C2.1 and C7.19 in their entirety. Originally published in 1981 and 1995 respectively.

1 Purpose

1.1 The purpose of this document is to standardize requirements for mixed acid etchants used in the semiconductor industry and testing procedures to support those standards. Test methods have been shown to give statistically valid results. This document also provides guidelines for grades of mixed acid etchants for which a need has been identified. In the case of the guidelines, the test methods may not have been statistically validated yet.

2 Scope

2.1 The scope of this document is all grades of mixed acid etchants used in the semiconductor industry.

3 Limitations

3.1 None.

4 Referenced Documents

SEMI C1 — Specifications for Reagents

SEMI C2 — Specifications for Etchants

5 Terminology

mixed acid etchant — any combination of nitric, hydrofluoric, and acetic acids with the relative composition expressed in terms of volumes of 70% nitric acid, 49% hydrofluoric acid, and glacial acetic acid, respectively. In the expression, all the relative volumes shall be reduced to a ratio of the smallest whole numbers. For example, a 3:1:2 mixed acid etchant would imply a mixture of 3 volumes of 70% nitric acid, 1 volume of 49% hydrofluoric acid, and 2 volumes of glacial acetic acid. If a component is absent, its relative volume shall be taken as zero. For example, a 3:1:0 mixed acid etchant would imply that no acetic acid is present.

6 Composition

6.1 The content of each of the components of a mixed acid etchant shall be expressed on a weight/weight basis of the 100% acids in the total mixture. For the volume-to-weight conversion, the densities shall be taken as 1.415, 1.153 g/mL, and 1.050 g/mL for 70% nitric acid, 49% hydrofluoric acid, and glacial acetic acid, respectively.

7 Tolerances

Nitric Acid:	± 1.0% (± 0.16 meq/g)
Hydrofluoric Acid:	± 0.5% (± 0.25 meq/g)
Acetic Acid:	± 1.0% (± 0.17 meq/g)

8 Requirements

8.1 The requirements for mixed acid etchants for Grade 1 and Tier A are listed in Table 1.

9 Grade 1 Procedures

9.1 *Total Acidity* — Accurately weigh a sample containing 30 to 40 milliequivalents of acidity in a polyethylene weighing bottle. Transfer with water to a 250 mL polyethylene beaker and dilute to approximately 100 mL. Add 10 drops of phenolphthalein indicator solution and titrate with 1 N standardized sodium hydroxide to a faint pink end point. Calculate the total acidity (A):

$$\text{Total Acidity}\left(\text{meq}/\text{g}\right) = \frac{\text{mL} \times \text{N of NaOH}}{\text{Weight of sample (g)}} = A$$

9.2 *Hydrofluoric Acid* — Accurately weigh a sample containing 0.3 to 0.5 g of hydrofluoric acid in a polyethylene weighing bottle. Transfer with water to a polyethylene beaker and dilute to approximately 100 mL. Add 10 drops of phenolphthalein indicator solution and titrate with 1 N or stronger sodium hydroxide solution to a faint pink endpoint. Add 25 mL of Acetate Buffer for Hydrofluoric Acid Determination and 1 g of Eriochrome Cyanine R indicator mixture. Mix continuously by magnetic stirring and titrate with standardized aluminum chloride solution to a pink-purple endpoint.

$$\%\ \text{Hydrofluoric Acid} = \frac{\text{mL} \times \text{HF factor of } AlCl_3 \text{ soln.}}{\text{Weight of sample (g)}}$$

9.3 *Nitric Acid* — Accurately weigh a sample containing 0.9 to 1.1 g of nitric acid in a polyethylene weighing bottle. Quantitatively transfer into a 100 mL volumetric flask containing 50 mL of 2% boric acid solution, dilute to volume with water, and mix thoroughly. Following the manufacturer's direction, ready a spectrophotometer and set the wavelength to 302 nm. Transfer the sample solution to a 1 cm fused silica cell and measure the absorbance of the sample solution versus water. Read from a previously established calibration curve the grams of nitric acid present in the sample solution (see SEMI C2, Section 3.2, Determination of Nitric Acid by Ultraviolet Absorption Spectrophotometry).

$$\% \text{ Nitric Acid} = \frac{\text{grams of } HNO_3 \text{ calibration curve} \times 100}{\text{Weight of sample } (g)}$$

9.4 *Acetic Acid* — The acetic acid content is calculated by deducting the acidity found for each of the other components from the value for the total acidity.

$$\% \text{ Acetic Acid} = \left[A - \frac{\%HF}{2.001} - \frac{\%HNO_3}{6.302} \right] \times 6.005$$

9.5 *Arsenic and Antimony (as As)* — To 50 g of sample in a polyfluorocarbon dish, add 5 mL of hydrochloric acid and 5 mL of sulfuric acid. Mix gently and evaporate in a sandbath in a hood to dense fumes of sulfur trioxide. Cool, cautiously add 10 mL of water, and re-evaporate to dense fumes of sulfur trioxide. Cool, and cautiously wash into a generator flask with water to make a volume of 35 mL. Proceed as described in the General Method for Arsenic (and Antimony) under SEMI C1, Section 3.4.5, starting with the sentence which begins, "Swirl the flask…" Any red color in the silver diethyldithiocarbamate solution of the sample should not exceed that in the standard containing 0.0015 mg of arsenic (As).

9.6 *Trace Element Contents* — Determine the levels of specified trace elements and establish that they do not exceed the specification limits using a suitable emission spectrographic procedure (see SEMI C1, Section 3.5, for Guidelines for Determination of Trace Elements by Emission Spectrography).

10 Grade 2 Procedures

10.1 This section does not apply to this chemical.

11 Grade 3 Procedures

11.1 This section does not apply to this chemical.

12 Grade 4 Procedures

12.1 This section does not apply to this chemical.

13 Grade 5 Procedures

13.1 This section does not apply to this chemical.

14 VLSI Grade Procedures

14.1 This section does not apply to this chemical.

15 Tier A Procedures

15.1 Standardized test methods are being developed for all parameters at the purity levels indicated. Until standardized test methods are published, test methodology shall be determined by user and producer. The Process Chemicals Committee considers a test method to be valid only if there is a documented recovery study showing a recovery of 75 - 125%. Recovery is for a known sample spike at 50% of the specified level.

16 Tier B Procedures

16.1 This section does not apply to this chemical.

17 Tier C Procedures

17.1 This section does not apply to this chemical.

18 Tier D Procedures

18.1 This section does not apply to this chemical.

SEMI C35-0301
SPECIFICATIONS AND GUIDELINE FOR NITRIC ACID

These specifications and this guideline were technically approved by the Global Process Chemicals Committee and are the direct responsibility of the North American Process Chemicals Committee. Current edition approved by the North American Regional Standards Committee on October 17, 1999. Initially available at www.semi.org February 2001; to be published March 2001. This document replaces SEMI C1.12, C7.6, and C8.6 in their entirety. Originally published in 1979, 1990, and 1992 respectively; previously published June 1999.

1 Purpose

1.1 The purpose of this document is to standardize requirements for nitric acid used in the semiconductor industry and testing procedures to support those standards. Test methods have been shown to give statistically valid results. This document also provides guidelines for grades of nitric acid for which a need has been identified. In the case of the guidelines, the test methods may not have been statistically validated yet.

2 Scope

2.1 The scope of this document is all grades of nitric acid used in the semiconductor industry.

2.2 These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 None.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI C1 — Specifications for Reagents

4.2 *ASTM Standards*[1]

ASTM D5127 — Standard Guide for Ultra Pure Water Used in the Electronics and Semiconductor Industry

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 None.

6 Physical Property (for information only)

Density at 25°C	1.42 g/mL

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, Pennsylvania 19428-2959, USA. Telephone: 610.832.9585, Fax: 610.832.9555. Website: www.astm.org

7 Requirements

7.1 The requirements for nitric acid for Grades 1 and 2 and Tier B are listed in Table 1.

8 Grade 1 Procedures

NOTE 2: Each laboratory is responsible for verifying the validity of the method within its own operation.

8.1 *Assay* — Accurately weigh a small glass-stoppered conical flask containing about 15 mL of water. Deliver from a pipet about 2 mL of the sample near the water surface, stopper immediately, cool, and reweigh. Dilute to about 50 mL with water, add 0.10 mL of methyl orange indicator solution, and titrate with standardized 1 N sodium hydroxide to a red to yellow color change.

$$\%\ \text{Assay} = \frac{\text{mL} \times \text{N of NaOH} \times 6.301}{\text{Weight of sample (g)}}$$

8.2 *Color* — Dilute 2.0 mL of platinum-cobalt stock solution (APHA No. 500) to 100 mL with water. Compare this standard (APHA No. 10) with 100 mL of sample in Nessler tubes. View vertically over a white background. The sample must be no darker than the standard.

8.3 *Chloride* — Dilute 84 mL (120 g) of sample with 10 mL of water, add 1 mL of silver nitrate reagent solution, and evaporate to dryness on a steam bath in a hood. Dissolve the residue in 0.5 mL of ammonium hydroxide, dilute with 20 mL of water, and add 1.5 mL of nitric acid. Any turbidity produced should be no greater than that produced when 0.01 mg of chloride ion (Cl) is treated as the sample.

8.4 *Phosphate* — To 35 mL (50 g) of sample add 10 mL of sodium carbonate reagent solution and evaporate to dryness on a steam bath in a hood. Dissolve the residue in 25 mL of 0.5 N sulfuric acid. Add 1 mL of ammonium molybdate reagent solution and 1 mL of p-(methylamino)phenol sulfate reagent solution. Allow to stand at room temperature for 2 hours. Any blue color produced should be no greater than that produced when 0.01 mg of phosphate ion (PO_4) is treated as the sample.

8.5 *Sulfate* — To 70 mL (100 g) of sample add 10 mL of sodium carbonate reagent solution and evaporate to dryness in a hood. Dissolve the residue in 10 mL of water and 1 mL of dilute hydrochloric acid (1 + 19); filter if necessary. Add 1 mL of barium chloride reagent solution, mix, and allow to stand for 10 minutes. Any turbidity developed should be no greater than that produced when 0.05 mg of sulfate ion (SO_4) is treated as the sample.

8.6 *Arsenic and Antimony (as As)* — To 141 mL (200 g) of sample in a 400 mL beaker add 5 mL of sulfuric acid, and evaporate to dense fumes of sulfur trioxide in a hood. Cool, cautiously add 10 mL of water, and again evaporate to dense fumes of sulfur trioxide. Cool, and cautiously wash into a generator flask with water to make a volume of 35 mL. Proceed as described in the General Method for Arsenic (and Antimony) under SEMI C1, Section 3.4.5, starting with the sentence which begins, "Swirl the flask...." Any red color in the silver diethyldithiocarbamate solution of the sample should be no greater than that of the standard containing 0.001 mg of arsenic (As).

8.7 *Trace Metal Analysis*

8.7.1 *Gold (Au)* — Analyze by graphite atomic absorption using the manufacturer's recommended procedure. This technique has been shown to give satisfactory results using a 1:4 dilution and Zeeman background correction. Each laboratory must determine the appropriate dilution and background correction for its instrument to meet the specification limit.

8.7.2 The following method has given satisfactory results in determining trace metal impurities at the value specified for each of the following trace metals: aluminum (Al), boron (B), calcium (Ca), chromium (Cr), copper (Cu), iron (Fe), lead (Pb), magnesium (Mg), manganese (Mn), nickel (Ni), potassium (K), sodium (Na), tin (Sn), titanium (Ti), and zinc (Zn). Alternate methods may be used as long as appropriate studies demonstrate recovery between 75–125% of a known sample spike for half of the value of each specified item.

8.7.3 *Special Reagents*

8.7.3.1 *Nitric Acid, Ultra Pure* — Use nitric acid specified for ultra low metal ion content.

8.7.3.2 *2% Nitric Acid Solution* — Dilute 20 mL of ultra pure nitric acid to 1 L using water meeting the criteria for Type E1.1 in ASTM D5127.

8.7.4 *Sample Preparation*

8.7.4.1 In a clean environment, place 250 g of sample in a PTFE evaporating dish. Slowly evaporate on a hot plate, avoiding loss of sample by effervescence or spattering until approximately 2 mL of liquid remains. Cool, and transfer quantitatively to a 50 mL volumetric flask using 2% nitric acid for rinsing and dilution to volume. Run a reagent blank.

8.7.5 *Analysis*

8.7.5.1 Using the acid sample and reagent blank, analyze group 1 elements by flame atomic absorption spectroscopy and all other elements by plasma emission spectroscopy.

9 Grade 2 Procedures

NOTE 3: Each laboratory is responsible for verifying the validity of the method within its own operation.

9.1 *Non-Metal Impurities* — See Section 8, which contains procedures for the following tests:

Assay

Color (APHA)

Chloride

Phosphate

Sulfate

9.2 *Trace Metals Analysis*

9.2.1 The following method has given satisfactory results in determining metal ion impurities at the values specified for each of the following metals: aluminum (Al), antimony (Sb), arsenic (As), barium (Ba), beryllium (Be), bismuth (Bi), boron (B), calcium (Ca), chromium (Cr), cobalt (Co), copper (Cu), gallium (Ga), germanium (Ge), gold (Au), iron (Fe), lead (Pb), lithium (Li), magnesium (Mg), manganese (Mn), molybdenum (Mo), nickel (Ni), niobium (Nb), potassium (K), silver (Ag), sodium (Na), strontium (Sr), tantalum (Ta), tin (Sn), titanium (Ti), vanadium (V), zinc (Zn), and zirconium (Zr). Alternate methods may be used as long as appropriate studies demonstrate a recovery between 75 - 125% of a known sample spike for half of the value of each specified element.

9.2.2 *Special Reagents*

9.2.2.1 *Nitric Acid, Ultra Pure* — Use nitric acid specified for low metal ion content.

9.2.2.2 *7.0% Nitric Acid Solution* — Dilute 20 g of ultrapure nitric acid to 200 g using water meeting the criteria for Type E1.1 in ASTM D5127.

9.2.2.3 *Water* — The water used for all the dilution, calibration and standards should meet at a minimum the criteria for Type E1.1 in ASTM D5127 in regard to cation analysis.

9.2.2.4 *Indium Internal Standard* — Make up a indium internal standard solution to a concentration of 20 μg/mL (ppm) from a appropriate concentrated indium standard solution.

9.2.3 *Sample Preparation*

9.2.3.1 In a clean environment, place 2.00 g of sample into a tared FEP bottle (30 mL), dilute with Type E1.1 water to a final weight of 20.0 g. Add 20 µL of the indium internal standard solution. Run a reagent blank.

9.2.4 *Analysis*

9.2.4.1 Using the prepared solutions and blanks, analyze sodium, potassium, calcium and iron by graphite furnace atomic absorption (GFAA) and the remaining elements by inductively coupled plasma mass spectrometry (ICP/MS). For calibration, the standards are made up with the 7.0% nitric acid solution and the indium internal standard such that the final concentration is 20 ng/g of indium.

10 Grade 3 Procedures

10.1 This section does not apply to this chemical.

11 Grade 4 Procedures

11.1 This section does not apply to this chemical.

12 Grade 5 Procedures

12.1 This section does not apply to this chemical.

13 VLSI Grade Procedures

13.1 This section does not apply to this chemical.

14 Tier A Procedures

14.1 This section does not apply to this chemical.

15 Tier B Procedures

15.1 Standardized test methods are being developed for all parameters at the purity levels indicated. Until standardized test methods are published, test methodology shall be determined by user and producer. The Process Chemical Committee considers a test method to be valid only if there is a documented recovery study showing a recovery of 75–125%. Recovery is for a known sample spike at 50% of the specified level.

16 Tier C Procedures

16.1 This section does not apply to this chemical.

17 Tier D Procedures

17.1 This section does not apply to this chemical.

SEMI C36-0301
SPECIFICATIONS FOR PHOSPHORIC ACID

These specifications were technically approved by the Global Process Chemicals Committee and are the direct responsibility of the North American Process Chemicals Committee. Current edition approved by the North American Regional Standards Committee on October 17, 1999. Initially available at www.semi.org February 2001; to be published March 2001. This document replaces SEMI C1.13, C1.27, C7.24, and C8.10 in their entirety. Originally published in 1981, 1993, 1997, and 1993 respectively; previously published February 2000.

NOTE: Information in this standard pertaining to Tier B phosphoric acid was superseded by information pertaining to Grade 3 phosphoric acid and was removed in February 2000.

1 Purpose

1.1 The purpose of this document is to standardize requirements for phosphoric acid used in the semiconductor industry and testing procedures to support those standards. Test methods have been shown to give statistically valid results. This document also provides guidelines for grades of phosphoric acid for which a need has been identified. In the case of the guidelines, the test methods may not have been statistically validated yet.

2 Scope

2.1 The scope of this document is all grades of phosphoric acid used in the semiconductor industry.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 None.

4 Referenced Standards

4.1 *ASTM Standards*[1]

ASTM D5127 — Standard Guide for Ultra Pure Water Used in the Electronics and Semiconductor Industry

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 None.

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, Pennsylvania 19428-2959, USA. Telephone: 610.832.9585, Fax: 610.832.9555. Website: www.astm.org

6 Physical Property (for information only)

Density at 25°C	80%	1.64 g/mL
	86%	1.70 g/mL

7 Requirements

7.1 The requirements for phosphoric acid for Grades 1, 2, and 3 are listed in Table 1.

8 Grade 1 Procedures

8.1 *Assay* — Weigh to the nearest 1 mg about 1 mL of sample in a 250 mL glass-stoppered flask, dilute with 120 mL of water, add 0.5 mL of thymolphthalein indicator solution, and titrate with standardized 1 N sodium hydroxide to the first appearance of a blue color against a white background.

$$\%\ \text{Assay} = \frac{\text{mL} \times \text{N of NaOH} \times 4.900}{\text{Weight of sample (g)}}$$

8.2 *Chloride* — Dilute 9 mL (15 g) of sample with 25 mL of water, and add 0.5 mL of nitric acid and 1 mL of silver nitrate reagent solution. Any turbidity produced should be no greater than that produced when 0.015 mg of chloride ion (Cl) is treated as the sample.

8.3 *Nitrate* — Prepare the following solutions:

Sample Solution A:	Add 3 mL (5 g) of sample to 2 mL of water, dilute to 50 mL with brucine sulfate reagent solution and mix.
Control Solution B:	Add 3 mL (5 g) of sample to 0.025 mg of nitrate ion (NO_3). Dilute to 50 mL with brucine sulfate reagent solution, and mix.
Blank Solution C:	Use 50 mL of the brucine sulfate reagent solution.

8.3.1 Heat the three solutions in a preheated (boiling water) bath for 10 minutes. Cool rapidly in an ice bath to room temperature. Set a spectrophotometer at 410 nm and, using 1 cm cells, adjust the instrument to read zero absorbance with Blank Solution C in the light path. Then determine the absorbance of Sample Solution A. Adjust the instrument to read zero absorbance with Sample Solution A in the light path and determine the absorbance of Control Solution B. The absorbance of Sample Solution A should not exceed that of Control Solution B.

8.4 *Sulfate*

8.4.1 The following inductively coupled plasma (ICP) method has given satisfactory results for the determination of sulfate (SO_4) by the analysis of sulfur (S) and subsequent calculation to determine the stoichiometric equivalent of sulfate.

NOTE 2: While this method has been shown to accurately determine sulfate concentration in phosphoric acid, the ICP methodology actually evaluates sulfur. Therefore, other sulfur species (organic, etc.) will also be determined by this method, and the "calculated" sulfate value may be higher than the actual sulfate concentration in a given sample.

8.4.2 *Special Reagents*

8.4.2.1 *Water* — The water used for all dilution, calibration and standards should meet at a minimum, the criteria for Type E1.1 in ASTM D5127.

8.4.2.2 *Scandium Internal Standard* — A scandium standard solution is utilized such that final diluted samples will have a scandium concentration of 40 ppm.

8.4.3 *Sample Preparation*

8.4.3.1 Dilute 20 g of phosphoric acid to 100 mL with water. (An aliquot of the concentrated scandium standard solution should also be added during the dilution process such that the final diluted sample will have a scandium concentration of 40 ppm.)

8.4.4 *Analysis*

8.4.4.1 Using the prepared sample, analyze the sulfur content using inductively coupled plasma (ICP) spectroscopy that has been standardized using appropriate sulfur standard solutions. A wavelength of 180.731 nm has been shown to give satisfactory results.

8.4.5 *Calculation*

8.4.5.1 The associated sulfate (SO_4) concentration is determined using the stoichiometric conversion ($SO_4 = 3 \times S$).

8.5 *Trace Metal Analysis*

8.5.1 The following method has given satisfactory results in determining trace metal impurities at the value specified for each of the following trace metals: arsenic (As), gold (Au), cobalt (Co), chromium (Cr), nickel (Ni), lead (Pb), and antimony (Sb). Alternate methods may be used as long as appropriate studies demonstrate recovery between 75–125% of a known sample spike for half of the value of each item specified.

8.5.2 *Special Reagents*

8.5.2.1 *Nitric Acid, Ultra Pure* — Use nitric specified for ultra low metal ion content.

8.5.2.2 *Sample Preparation* — In a clean environment, weigh 1.00 g (5.00 g for arsenic) of sample into each of two 30 mL polypropylene cups. Add 0.2 mL ultra pure nitric acid to each cup. Make standard addition to one cup. Dilute both cups to 10.0 g using water meeting the criteria for Type E1.1 in ASTM D5127. Mix. Prepare reagent blank.

8.5.2.3 *Analysis* — Using the solutions from Section 8.5.2.2 and reagent blank, analyze elements specified by graphite furnace atomic absorption spectroscopy using manufacturer's recommended procedure.

8.5.3 The following method has given satisfactory results in determining trace metal impurities at the value specified for each of the following trace metals: aluminum (Al), calcium (Ca), copper (Cu), iron (Fe), lithium (Li), magnesium (Mg), manganese (Mn), potassium (K), sodium (Na), strontium (Sr), titanium (Ti), and zinc (Zn). Alternate methods may be used as long as appropriate studies demonstrate recovery between 75–125% of a known sample spike for half of the value of each item specified.

8.5.3.1 *Sample Preparation* — In a clean environment, weigh 5.00 g of sample into each of two 30 mL polypropylene cups. To one of the cups make standard addition. Add 5.00 g of water meeting the criteria for Type E1.1 in ASTM D5127 to each cup. Mix.

8.5.3.2 *Analysis* — Using the solutions from Section 8.5.3.1 and reagent blank, analyze elements specified by plasma emission spectroscopy using manufacturer's recommended procedure.

9 Grade 2 Procedures

9.1 *Assay* — Weigh to the nearest 1 mg about 1 mL of sample in a 250 mL glass-stoppered flask, dilute with 120 mL of water, add 0.5 mL of thymolphthalein indicator solution, and titrate with standardized 1 N sodium hydroxide to the first appearance of a blue color against a white background.

$$\% \text{ Assay} = \frac{\text{mL} \times \text{N of NaOH} \times 4.900}{\text{Weight of sample(g)}}$$

9.2 *Chloride* — Dilute 9 mL (15 g) of sample with 25 mL of water, and add 0.5 mL of nitric acid and 1 mL of silver nitrate reagent solution. Any turbidity produced should be no greater than that produced when 0.015 mg of chloride ion (Cl) is treated as the sample.

9.3 *Nitrate* — Prepare the following solutions:

Sample Solution A:	Add 3 mL (5 g) of sample to 2mL of water. Dilute to 50 mL with brucine sulfate reagent solution, and mix.
Control Solution B:	Add 3 mL (5 g) of sample to 0.025 mg of nitrate ion (NO_3). Dilute to 50 mL with brucine sulfate reagent solution, and mix.
Blank Solution C:	Use 50 mL of the brucine sulfate reagent solution.

9.3.1 Heat the three solutions in a preheated (boiling water) bath for 10 minutes. Cool rapidly in an ice bath to room temperature. Set a spectrophotometer at 410 nm and, using 1 cm cells, adjust the instrument to read zero absorbance with Blank Solution C in the light path. Then determine the absorbance of Sample Solution A. Adjust the instrument to read zero absorbance with Sample Solution A in the light path and determine the absorbance of Control Solution B. The absorbance of Sample Solution A should not exceed that of Control Solution B.

9.4 *Sulfate*

9.4.1 The following inductively coupled plasma (ICP) method has given satisfactory results for the determination of sulfate (SO_4) by the analysis of sulfur (S) and subsequent calculation to determine the stoichiometric equivalent of sulfate.

NOTE 3: While this method has been shown to accurately determine sulfate concentration in phosphoric acid, the ICP methodology actually evaluates sulfur. Therefore, other sulfur species (organic, etc.) will also be determined by this method, and the “calculated” sulfate value may be higher than the actual sulfate concentration in a given sample.

9.4.2 *Special Reagents*

9.4.2.1 *Water* — The water used for all dilution, calibration, and standards should meet, at a minimum, the criteria for Type E1.1 in ASTM D5127.

9.4.2.2 *Scandium Internal Standard* — A scandium standard solution is utilized such that final diluted samples will have a scandium concentration of 40 ppm.

9.4.3 *Sample Preparation*

9.4.3.1 Dilute 20 g of phosphoric acid to 100 mL with water. (An aliquot of the concentrated scandium standard solution should also be added during the dilution process such that the final diluted sample will have a scandium concentration of 40 ppm.)

9.4.4 *Analysis*

9.4.4.1 Using the prepared sample, analyze the sulfur content using inductively coupled plasma (ICP) spectroscopy that has been standardized using appropriate sulfur standard solutions. A wavelength of 180.731 nm has been shown to give satisfactory results.

9.4.5 *Calculation*

9.4.5.1 The associated sulfate (SO_4) concentration is determined using the stoichiometric conversion ($SO_4 = 3 \times S$).

9.5 *Trace Metal Analysis*

9.5.1 The following method has given satisfactory results in determining trace metal impurities at the value specified for each of the following trace metals: aluminium (Al), antimony (Sb), arsenic (As), cadmium (Cd), calcium (Ca), chromium (Cr), cobalt (Co), copper (Cu), gold (Au), iron (Fe), lead (Pb), lithium (Li), magnesium (Mg), manganese (Mn), nickel (Ni), potassium (K), sodium (Na), strontium (Sr), titanium (Ti), and zinc (Zn). Alternate methods may be used as long as appropriate studies demonstrate recovery between 75–125% of a known sample spike for half of the value of each item specified.

9.5.1.1 *Special Reagents*

9.5.1.1.1 *Phosphoric Acid, Ultra Pure* — Use phosphoric acid specified for ultra low metal ion content.

9.5.1.1.2 *Nitric Acid, Ultra Pure* — Use nitric acid specified for ultra low metal ion content.

9.5.1.1.3 *Water* — The water used for all dilution, calibration, and standards should meet, at a minimum, the criteria for Type E1.1 in ASTM D5127.

9.5.1.1.4 *Internal Standard Stock Solution* — An internal standard stock solution containing beryllium (Be), germanium (Ge), indium (In), lutetium (Lu), and scandium (Sc) is utilized such that final measured solutions will have a concentration of 100 ppb of each internal standard element.

9.5.1.1.5 *External Standard Stock Solution* — An external standard stock solution containing the elements in Section 9.5.1 and the internal standard elements in Section 9.5.1.1.4 is utilized such that final diluted external calibration standards will have appropriate concentrations for sample elements and will contain 100 ppb of internal standard elements.

9.5.2 *Sample Preparation* — In a clean environment, weigh 4.00 g of sample into a 100 mL polypropylene flask. Add an aliquot of the internal standard stock solution such that the final diluted sample will have a concentration of 100 ppb of each internal standard element. Add 2 mL of nitric acid, ultra pure, and dilute to 100 mL with Type E1.1 water.

9.5.2.1 *Analysis* — Analyze elements utilizing inductively coupled plasma mass spectrometry (ICP - MS). Calibrate the sample elements with matrix matched blank and external standards.

10 Grade 3 Procedures

10.1 *Assay* — Weigh to the nearest 1 mg about 1 mL of sample in a 250 mL glass-stoppered flask, dilute with 120 mL of water, add 0.5 mL of thymolphthalein indicator solution, and titrate with standardized 1 *N* sodium hydroxide to the first appearance of a blue color against a white background.

10.2 *Chloride* — Dilute 9 mL (15 g) of sample with 25 mL of water, and add 0.5 mL of nitric acid and 1 mL of silver nitrate reagent solution. Any turbidity produced should be no greater than that produced when 0.015 mg of chloride ion (Cl) is treated as the sample.

10.3 *Nitrate* — Prepare the following solutions:

Sample Solution A:	Add 3 mL (5 g) of sample to 2 mL of water. Dilute to 50 mL with brucine sulfate reagent solution, and mix.
Control Solution B:	Add 3 mL (5 g) of sample to 0.025 mg of nitrate ion (NO_3) Dilute to 50 mL with brucine sulfate reagent solution, and mix.
Blank Solution C:	Use 50 mL of the brucine sulfate reagent solution.

10.3.1 Heat the three solutions in a preheated (boiling water) bath for 10 minutes. Cool rapidly in an ice bath to room temperature. Set a spectrophotometer at 410 nm and, using 1 cm cells, adjust the instrument to read zero absorbance with Blank Solution C in the light path. Then determine the absorbance of Sample Solution A. Adjust the instrument to read zero absorbance with Sample Solution A in the light path and determine the absorbance of Control Solution B. The absorbance of Sample Solution A should not exceed that of Control Solution B.

10.4 *Sulfate*

10.4.1 The following inductively coupled plasma (ICP) method has given satisfactory results for the determination of sulfate (SO_4) by the analysis of sulfur (S) and subsequent calculation to determine the stoichiometric equivalent of sulfate.

NOTE 3: While this method has been shown to accurately determine sulfate concentration in phosphoric acid, the ICP method actually evaluates sulfur. Therefore, other sulfur species (organic, etc.) will also be determined by this method, and the "calculated" sulfate value may be higher than the actual sulfate concentration in a given sample.

10.4.2 *Special Reagents*

10.4.2.1 *Water* — The water used for all dilution, calibration, and standards should meet, at a minimum, the criteria for Type E1.1 in ASTM D5127.

10.4.2.2 *Scandium Internal Standard* — A scandium standard solution is utilized such that final diluted samples will have a scandium concentration of 40 ppm.

10.4.3 *Sample Preparation*

10.4.3.1 Dilute 20 g of phosphoric acid to 100 mL with water. (An aliquot of the concentrated scandium standard solution should also be added during the dilution process such that the final diluted sample will have a scandium concentration of 40 ppm.)

10.4.4 *Analysis*

10.4.4.1 Using the prepared sample, analyze the sulfur content using inductively coupled plasma (ICP) spectroscopy that has been standardized using appropriate sulfur standard solutions. A wavelength of 180.731 nm has been shown to give satisfactory results.

10.4.5 *Calculation*

10.4.5.1 The associated sulfate (SO_4) concentration is determined using the stiochiometric conversion ($SO_4 = 3 \times S$).

10.5 *Trace Metal Analysis*

10.5.1 The following method has given satisfactory results in determining trace metal impurities at the value specified for each of the following trace metals: aluminium (Al), antimony (Sb), arsenic (As), barium (Ba), boron (B), cadmium (Cd), calcium (Ca), chromium (Cr), cobalt (Co), copper (Cu), gold (Au), iron (Fe), lead (Pb), lithium (Li), magnesium (Mg), manganese (Mn), nickel (Ni), potassium (K), silicon (Si), sodium (Na), strontium (Sr), titanium (Ti), and zinc (Zn). Alternate methods may be used as long as appropriate studies demonstrate recovery between 75–125% of a known sample spike for half of the value of each item specified.

10.5.1.1 *Special Reagents*

10.5.1.1.1 *Phosphoric Acid, Ultra Pure* — Use phosphoric acid specified for ultra low metal ion content for preparation of matrix matched calibration standards.

10.5.1.1.2 *Water* — The water used for all dilution, calibration, and standards should meet, at a minimum, the criteria for Type E1.1 in ASTM D5127.

10.5.1.1.3 *Internal Standard Stock Solution* — An internal standard stock solution containing beryllium (Be), germanium (Ge), indium (In), and lutetium (Lu) is utilized such that final measured solutions will have concentrations of Be - 10 ppb, Ge - 20 ppb, In - 5 ppb, and Lu - 5 ppb as internal standard elements.

10.5.1.1.4 *External Standard Stock Solution* — An external standard stock solution containing the elements in Section 10.5.1 is utilized such that final diluted external calibration standards will have appropriate concentrations for the measurement of the sample elements.

10.5.2 *Sample Preparation* — In a clean environment, weigh 5.00 g of sample into a 10 mL polypropylene sample tube. Add an aliquot of the internal standard stock solution such that the final diluted sample will have the concentration of internal standard elements in Section 10.5.1.1.3. Dilute contents to 10 mL with Type E1.1 water.

10.5.2.1 *Analysis* — Analyze elements using inductively coupled plasma mass spectrometry (ICP - MS). Calibrate the sample elements with matrix matched blank and external standards.

SEMI C37-0699
SPECIFICATION FOR PHOSPHORIC ETCHANTS

This specification was technically approved by the Global Process Chemicals Committee and is the direct responsibility of the North American Process Chemicals Committee. Current edition approved by the North American Regional Standards Committee on April 23, 1999. Initially available on SEMI OnLine May 1999; to be published June 1999. This document replaces SEMI C2.3 in its entirety. Originally published in 1981.

1 Purpose

1.1 The purpose of this document is to standardize requirements for phosphoric etchants used in the semiconductor industry and testing procedures to support those standards. Test methods have been shown to give statistically valid results. This document also provides guidelines for grades of phosphoric etchants for which a need has been identified. In the case of the guidelines, the test methods may not have been statistically validated yet.

2 Scope

2.1 The scope of this document is all grades of phosphoric etchants used in the semiconductor industry.

3 Limitations

3.1 None.

4 Referenced Documents

SEMI C1 — Specifications for Reagents

SEMI C2 — Specifications for Etchants

5 Terminology

5.1 *phosphoric etchant* — any combination of phosphoric, nitric, and acetic acids with the relative composition expressed in terms of 85% phosphoric acid, 70% nitric acid, and glacial acetic acid, respectively. In the expression, all the relative volumes shall be reduced to a ratio of the smallest whole numbers. For example, a 16:1:2 phosphoric etchant would imply a mixture of 16 volumes of 85% phosphoric acid, 1 volume of 70% nitric acid, and 2 volumes of glacial acetic acid. If a component is absent, its relative volume shall be taken as zero. For example, a 16:1:0 phosphoric etchant implies that no acetic acid is present.

6 Composition

6.1 The content of each of the components of a phosphoric etchant shall be expressed on a weight/weight basis of the 100 percent acid in the total mixture. For the volume-to-weight conversion, the densities shall be taken as 1.695, 1.415, and 1.050 g/mL for 85% phosphoric acid, 70% nitric acid, and glacial acetic acid, respectively.

7 Tolerances

7.1 The tolerances allowed for the absolute percentage of each of the components of a phosphoric etchant shall be:

Phosphoric Acid:	± 1.0% (± 0.20 meq/g)
Nitric Acid:	± 0.5% (± 0.08 meq/g)
Acetic Acid:	± 0.5% (± 0.08 meq/g)

8 Requirements

8.1 The requirements for phosphoric etchants for Grade 1 are listed in Table 1.

9 Grade 1 Procedures

9.1 *Total Acidity* — Weigh accurately 2.5 to 3.0 g of sample in a tared weighing bottle. Transfer with water to a 25 mL beaker and dilute to approximately 100 mL. Add 10 drops of thymolphthalein indicator solution and titrate with standardized 1 N sodium hydroxide solution to the blue endpoint. Calculate the total acidity (A):

$$\text{Total Acidity}\left(\text{meq}/\text{g}\right) = \frac{\text{mL} \times \text{N of NaOH}}{\text{Weight of sample (g)}} = \text{A}$$

9.2 *Phosphoric Acid* — Weigh accurately 2.5 to 3.0 g of sample in a tared weighing bottle. Quantitatively transfer the sample with 40 to 60 mL of water into a platinum or polyfluorocarbon dish. Evaporate the solution on a steam bath in a hood (1 to 2 hours). Rinse down the inner sides of the dish with 10 to 15 mL of water and re-evaporate for 1 hour. Cool and dilute with 50 mL of water. Add 10 drops of thymolphthalein indicator solution and titrate with standardized 1 N sodium hydroxide solution to the blue endpoint.

$$\%\ \text{Phosphoric Acid} = \frac{\text{mL} \times \text{N of NaOH} \times 4.900}{\text{Weight of sample (g)}}$$

9.3 *Nitric Acid* — Weigh accurately a sample containing 0.9 to 1.1 g of nitric acid in a tared 100 mL volumetric flask. Dilute to volume with water and mix thoroughly. Following the manufacturer's directions, ready a spectrophotometer and set the wavelengh to 302 nm. Transfer the sample solution to a 1 cm fused silica cell and measure the absorbance versus water. Read from a previously established calibration curve the grams of nitric acid present in the sample solulion (see

SEMI C2, Section 3.2, Determination of Nitric Acid by Ultraviolet Absorption Spectrophotometry).

$$\%\text{ Nitric Acid} = \frac{\text{grams of } HNO_3 \text{ calibration curve} \times 100}{\text{Weight of sample (g)}}$$

9.4 *Acetic Acid* — The acetic acid content is calculated by deducting the acidity found for each of the other components from the value for the total acidity.

$$\%\text{ Acetic Acid} = \left[A - \frac{\%H_3PO_4}{4.900} - \frac{\%HNO_3}{6.302}\right] \times 6.005$$

9.5 *Heavy Metals (as Pb)* — Dilute 6 g of sample to 30 mL with water. For the standard, add 0.02 mg of lead ion (Pb) to a 5 mL aliquot of this solution and dilute to 25 mL with water. For the sample, use the remaining 25 mL portion. Adjust the pH to between 3 and 4 (using a pH meter) with 1 N acetic acid or dilute ammonium hydroxide (10% NH_3), dilute to 40 mL with water, and mix. Add 10 mL of freshly prepared hydrogen sulfide water to each and mix. Any color in the solution of the sample should not exceed that in the standard.

9.6 *Antimony* — Dilute 20 mL (20 g) of stock solution to volume with water in a 100 mL volumetric flask and mix. For the standard, dilute 0.4 mg of antimony ion (Sb) to volume with water in a second 100 mL volumetric flask and mix. Following the manufacturer's directions, ready an atomic absorption spectrometer, use an air-acetylene flame, position the antimony hollow cathode lamp, and set the monochromator to the antimony resonance line of 217.6 nm. Employ deuterium lamp correction. Aspirate water and set to zero absorbance. Then aspirate, in succession, the standard, water, and sample. The absorbance of the sample should not exceed that of the standard. (see SEMI C1, Section 3.6, Guidelines for Determination of Trace Elements by Atomic Absorption Spectrometry.)

9.6.1 *Stock Solution for Sections 9.6 through 9.9* — To 200 g of sample in a 400 mL beaker, add 100 mL of water. Heat to boiling on a hot plate in a hood, and boil off approximately 100 mL. Cool slightly, add 100 mL of water, and again boil off about 100 mL. Cool, transfer to a 200 mL volumetric flask, and dilute to volume with water. One mL contains 1 gram of sample.

9.7 *Arsenic* — To 10 mL (10 g) of stock solution in a 125 mL arsine generator flask, add 30 mL of water 10 mL of ferric ammonium sulfate reagent solution, and then 2% potassium permanganate reagent solution dropwise to a permanent pink color. Add 1.5 g of sodium chloride and mix to dissolve. Heat nearly to boiling, remove from heat, and add 1 mL of stannous chloride reagent solution. Dilute to 60 mL and cool to 25°C ± 3°C. For the standard, add 20 mL of dilute sulfuric acid (1 + 4) to 0.005 mg of arsenic ion (As) in a second arsine generator flask and treat as above. Assemble the arsenic test apparatus (see SEMI C1, Section 3.4.2). Pack each scrubber tube with two pledgets of lead acetate-impregnated glass wool previously moistened with lead acetate solution, freed from excess solution by squeezing, and dried in a vacuum. Allow a small space between the two pledgets. Place 3.0 mL of silver diethyldithiocarbamate solution in each absorber tube and 10 g of zinc (granular) in each generator flask. Immediately connect the scrubber absorber assemblies to the sample and standard generator flasks. Place the flasks in a water bath maintained at 25°C ± 3°C. Swirl each flask occasionally. After 30 minutes disconnect the tubing from the generator flasks and transfer the silver diethyldithiocarbamate solutions to separate 1 cm photometer cells. Measure both sample and standard absorbances at 540 nm using the silver diethyldithiocarbamate solution as a blank. The absorbance of the sample should not exceed that of the standard.

9.8 *Manganese* — Add 25 mL (25 g) of stock solution to 100 mL of dilute sulfuric acid (1 + 9). For the standard, add 5 mL (5 g) of stock solution and 0.01 mg of manganese ion (Mn) to 100 mL of dilute sulfuric acid (1 + 9). To each solution, add 20 mL of nitric acid, heat to boiling, and continue boiling gently for 5 minutes. Cool slightly, add 0.25 g of potassium periodate, and again boil for 5 minutes. Any pink color in the sample solution should not exceed that in the standard.

9.9 *Copper, Iron, and Nickel* — Dilute 1 mL (1 g) of stock solution with 50 mL of water in a 100 mL beaker. Add 0.5 mL of ammonium hydroxide and cool. For the three-element standard, add 0.002 mg of copper ion (Cu), 0.01 mg of iron ion (Fe), and 0.003 mg of nickel ion (Ni) to 50 mL of water in a second 100 mL beaker.

9.9.1 Treat each solution as follows: Adjust the pH to 2.5 (using a pH meter) with dilute ammonium hydroxide (10% NH_3) or 10% hydrochloric acid. Transfer to a polyfluorocarbon-stoppered 250 mL separatory funnel. Rinse the beaker with water adjusted to pH 2.5 and add the rinsings to the funnel (the final volume should not exceed 100 mL). Add 10 mL of freshly prepared 1% ammonium 1-pyrrolidinecarbodithiolate solution and mix thoroughly. Add 10.0 mL of water-saturated methyl isobutyl ketone (that is, 4-methyl-2-pentanone), stopper, and shake vigorously for 3 minutes. Allow the layers to separate. Drain and discard the lower, aqueous layer; save the upper, organic layer.

9.9.2 Following the manufacturer's directions, ready the atomic absorption spectrometer for measurements in the absorbance mode and with the air-acetylene flame adjusted for aspiration of an organic solvent. For copper, align the copper hollow cathode lamp, set the wavelength to 324.7 nm, and zero the absorbance while aspirating methyl isobutyl ketone. Then aspirate the extract of the standard solution, solvent, and the extract of the sample solution. Record the absorbances. Proceed similarly for iron and nickel with measurements at 248.3 and 232.0 nm, respectively. For each of the three elements the absorbance of the sample extract should not exceed that of the standard extract (see SEMI C1, Section 3.6, Guidelines for Determination of Trace Elements by Atomic Absorption Spectrometry).

9.10 *Sodium, Lithium, Potassium, Calcium, Strontium, and Magnesium*

9.10.1 *Sample Solutions for the Determination of Sodium, Lithium, Potassium, Calcium, Strontium, and Magnesium by Atomic Absorption Spectrometry* — Thoroughly clean four 100 mL volumetric flasks and label them 1, 2, 3, 4, respectively. Transfer 20 mL (20 g) samples of stock solution into the four volumetric flasks. Add the quantities of cations as listed as follows:

CATION	FLASK	FLASK	FLASK	FLASK
	1	2	3	4
	Milligrams of Cation			
Sodium Ion (Na)	0.00	0.15	0.30	0.60
Lithium Ion (Li)	0.00	0.01	0.02	0.04
Potassium Ion (K)	0.00	0.10	0.20	0.40
Calcium Ion (Ca)	0.00	0.20	0.40	0.80
Strontium Ion (Sr)	0.00	0.05	0.10	0.20
Magnesium Ion (Mg)	0.00	0.05	0.10	0.20

9.10.2 *General Instructions* — Dilute each solution to volume with water and mix thoroughly. Following the manufacturer's directions, ready the atomic absorption spectrometer for measurements in the absorbance mode (see SEMI C1, Section 3.6, Guidelines for Determination of Trace Elements by Atomic Absorption Spectrometry). Determine each of the elements, using the conditions specified in Sections 9.10.3 through 9.10.8.

9.10.2.1 For each element plot on linear coordinate paper the absorbance versus the added quantity in milligrams of the cation added. Draw a straight line through the four points and extrapolate to zero absorbance. This intercept corresponds to the absolute amount, in milligrams, of the element being determined in Solution 1.

$$\text{ppm element} = \frac{\text{mg found} \times 1000}{\text{Weight of Sample (g)}}$$

9.10.3 *Sodium* — Using an air-acetylene flame and a sodium hollow cathode lamp, set the wavelength to 589.0 nm and zero the absorbance with water. Aspirate, and record the absorbances of each of the solutions, zeroing the absorbance with water between aspiration of the solutions. Calculate the amount of the sodium ion (Na) in Solution 1; this should not exceed 0.30 mg.

9.10.4 *Potassium* — Using an air-acetylene flame and a potassium hollow cathode lamp, set the wavelength to 766.5 nm and zero the absorbance using water. Aspirate, and record the absorbances of each of the four solutions, zeroing the absorbance with water between aspiration of the solutions. Calculate the amount of potassium ion (K) in Solution 1; this should not exceed 0.20 mg.

9.10.5 *Lithium* — Using an air-acetylene flame and a lithium hollow cathod lamp, set the wavelength to 670.8 and zero the absorbance with water. Aspirate and record the absorbances of each of the four solutions, zeroing the absorbance with water between aspiration of the solutions. Calculate the amount of lithium ion (Li) in sample Solution 1; this should not exceed 0.02 mg.

9.10.6 *Strontium* — Using a nitrous oxide-acetylene flame and a strontium cathode lamp, set the wavelength to 460.7 nm and zero the absorbance with water. Aspirate, and record the absorbances of each of the four solutions, zeroing the absorbance with water between aspiration of the solutions. Calculate the amount of strontium ion (Sr) in Solution 1; this should not exceed 0.10 mg.

9.10.7 *Calcium* — Using a nitrous oxide-acetylene flame and a calcium hollow lamp, set the wavelength to 422.7 nm and zero the absorbance with water. Aspirate, and record the absorbances of each of the four solutions, zeroing the absorbance with water between aspiration of the solutions. Calculate the amount of calcium ion (Ca) in Solution 1; this should not exceed 0.40 mg.

9.10.8 *Magnesium* — Thoroughly clean four 50 mL volumetric flasks and label them 1a, 2a, 3a, and 4a. Transfer 20 mL (4 g) from each of the four 100 mL volumetric flasks into the corresponding 50 mL flasks. Dilute each to volume and mix thoroughly. Using an air-acetylene flame, background corrections, and a magnesium hollow lamp, set the wavelength to 285.2 nm and zero the absorbance with water. Aspirate, and record the absorbances of each of the four solutions, zeroing the absorbance with water between aspiration of the solutions. Calculate the amount of magnesium ion (Mg) in Solution 1a; this should not exceed 0.02 mg.

SEMI C38-0699
GUIDELINE FOR PHOSPHORUS OXYCHLORIDE

This guideline was technically approved by the Global Process Chemicals Committee and is the direct responsibility of the North American Process Chemicals Committee. Current edition approved by the North American Regional Standards Committee on April 23, 1999. Initially available on SEMI OnLine May 1999; to be published June 1999. This document replaces SEMI C7.12 in its entirety. Originally published in 1991.

1 Purpose

1.1 The purpose of this document is to standardize requirements for phosphorus oxychloride used in the semiconductor industry and testing procedures to support those standards. Test methods have been shown to give statistically valid results. This document also provides guidelines for grades of phosphorus oxychloride for which a need has been identified. In the case of the guidelines, the test methods may not have been statistically validated yet.

2 Scope

2.1 The scope of this document is all grades of phosphorus oxychloride used in the semiconductor industry.

3 Limitations

3.1 None.

4 Referenced Documents

4.1 None.

5 Terminology

5.1 None.

6 Physical Property (for information only)

6.1 Not applicable.

7 Requirements

7.1 The requirements for phosphorus oxychloride for Tier A are listed in Table 1.

8 Grade 1 Procedures

8.1 This section does not apply to this chemical.

9 Grade 2 Procedures

9.1 This section does not apply to this chemical.

10 Grade 3 Procedures

10.1 This section does not apply to this chemical.

11 Grade 4 Procedures

11.1 This section does not apply to this chemical.

12 Grade 5 Procedures

12.1 This section does not apply to this chemical.

13 VLSI Grade Procedures

13.1 This section does not apply to this chemical.

14 Tier A Procedures

14.1 Standardized test methods are being developed for all parameters at the purity levels indicated. Until standardized test methods are published, test methodology shall be determined by user and producer. The Process Chemicals Committee considers a test method to be valid only if there is a documented recovery study showing a recovery of 75 - 125%. Recovery is for a known sample spike at 50% of the specified level.

15 Tier B Procedures

15.1 This section does not apply to this chemical.

16 Tier C Procedures

16.1 This section does not apply to this chemical.

17 Tier D Procedures

17.1 This section does not apply to this chemical.

Table 1 Impurity Limits and Other Requirements for Phosphorus Oxychloride

Previous SEMI Reference #	C7.12-91
	Tier A
	(Guideline)
Assay	99.9% min
Color (APHA)	5 max
Hydroxyl	0.1 absorbance units (see NOTE 1)
Aluminum (Al)	10 ppb max
Arsenic (As)	7 ppb max
Barium (Ba)	1 ppb max
Bismuth (Bi)	1 ppb max
Calcium (Ca)	6 ppb max
Chromium (Cr)	1 ppb max
Cobalt (Co)	1 ppb max
Copper (Cu)	3 ppb max
Gallium (Ga)	1 ppb max
Gold (Au)	1 ppb max

NOTE 1: Absorbance for the 4000 to 2700 cm^{-1} for 5 mm optical path length.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI

SEMI C39-0699
SPECIFICATION FOR POTASSIUM HYDROXIDE PELLETS

This specification was technically approved by the Global Process Chemicals Committee and is the direct responsibility of the North American Process Chemicals Committee. Current edition approved by the North American Regional Standards Committee on April 23, 1999. Initially available on SEMI OnLine May 1999; to be published June 1999. This document replaces SEMI C1.14 in its entirety. Originally published in 1978.

1 Purpose

1.1 The purpose of this document is to standardize requirements for potassium hydroxide pellets used in the semiconductor industry and testing procedures to support those standards. Test methods have been shown to give statistically valid results. This document also provides guidelines for grades of potassium hydroxide pellets for which a need has been identified. In the case of the guidelines, the test methods may not have been statistically validated yet.

2 Scope

2.1 The scope of this document is all grades of potassium hydroxide pellets used in the semiconductor industry.

3 Limitations

3.1 None.

4 Referenced Documents

SEMI C1 — Specifications for Reagents

5 Terminology

5.1 None.

6 Physical Property (for information only)

6.1 Not applicable.

7 Requirements

7.1 The requirements for potassium hydroxide pellets for Grade 1 are listed in Table 1.

8 Grade 1 Procedures

8.1 *Assay* — Weigh accurately 35 to 40 g of sample in a closed weighing bottle. Transfer to a 500 mL volumetric flask, dissolve in carbon dioxide-free water, cool to 25°C, dilute to the mark with carbon dioxide free water, and mix thoroughly. Transfer 25.0 mL of this solution to a 500 mL glass-stoppered flask, dilute with 175 mL of carbon dioxide-free water, add 5 mL of barium chloride reagent solution, shake, and allow to stand for five minutes. Add 0.15 mL of phenolphthalein indicator solution and titrate with 1 N hydrochloric acid. (Save this solution for the potassium carbonate test.)

$$\% \text{ Assay} = \frac{\text{mL} \times \text{N of HCl} \times 112.2}{\text{Weight of sample (g)}}$$

8.2 *Potassium Carbonate (K_2CO_3)* — To the above titrated solution, add 0.15 mL of methyl orange indicator solution and continue the titration with 1 N hydrochloric acid. The additional hydrochloric acid is equivalent to that consumed by the potassium carbonate.

$$\% \text{ K}_2\text{CO}_3 = \frac{\text{mL} \times \text{N} \times \text{HCl} \times 138.2}{\text{Weight of sample (g)}}$$

8.3 *Ammonium Hydroxide Precipitate* — Weigh about 10 g of sample and dissolve in about 100 mL of water.

8.3.1 Cautiously add 12 mL of sulfuric acid to 15 mL of water, cool, then cautiously add the mixture to the solution of the sample and evaporate to dense fumes. Cool, dissolve the residue in 130 mL of hot water, and add ammonium hydroxide until the solution is just basic to methyl red.

8.3.2 Heat to boiling, filter, wash with hot water, and ignite. The weight of the residue should not exceed 2 mg.

8.4 *Insoluble Matter* — Dissolve 50 g of sample in 250 mL of carbon dioxide-free water in a 500 mL stoppered flask and cool to 25°C. The solution should be clear and colorless. Filter through a tared, medium-porosity filtering crucible and wash thoroughly with hot water. Dry the crucible at 105°C for 1 hour, cool, and weigh the residue. The weight of the residue should not exceed 2.5 mg.

8.5 *Stock Solution for 8.6-8.11, 8.13-8.14* — Dissolve 50 g of sample in 250 mL of carbon dioxide-free water and dilute with such water to 500 mL. One mL contains 0.10 g of sample. Store in a plastic container.

8.6 *Nitrogen Compounds* — Dilute 20 mL of the Stock Solution with 50 mL of water in a flask connected through a spray trap to a condenser, the end of which dips beneath the surface of 10 mL of 0.1 N hydrochloric acid. For the standard, take 50 mL of water in a similar flask, and add 10 mL of the Stock Solution and 1 mL of the nitrogen standard solution. To each flask add 0.5 g of aluminum wire in small pieces, allow to stand for 1 hour, and slowly distill about 35 mL. To each distillate add 2 mL of freshly boiled 10% sodium hydroxide reagent solution, dilute with water to 50 mL, and add 2 mL of Nessler reagent. Any color in the solution of the sample should not exceed that in the standard.

8.7 *Chloride* — Dilute 10 mL of the Stock Solution with water to 50 mL. Filter if necessary through a chloride-free filter. To 10 mL of this solution, add 5 mL of water, 2 mL of nitric acid, and 1 mL of silver nitrate reagent solution. Any turbidity developed should not exceed that produced by 0.02 mg of chloride ion (Cl) in an equal volume of solution containing the quantities of reagent used in the test.

8.8 *Phosphate* — To 40 mL of the Stock Solution, add 10 mL of hydrochloric acid and evaporate to dryness on a steam bath. Dissolve the residue in 25 mL of 0.5 N sulfuric acid. Add 1 mL of ammonium molybdate reagent solution and 1 mL of p-(methylamino)phenol sulfate reagent solution. Allow to stand for 2 hours at room temperature. Any blue color developed should not exceed that produced when 0.02 mg of phosphate ion (PO_4) is treated as the sample.

8.9 *Sulfate* — To 20 mL of the Stock Solution, add 5 mL of hydrochloric acid and evaporate to dryness on a steam bath. Dissolve the residue in 20 mL of water and evaporate again to dryness. Dissolve the residue in 20 mL of water, filter if necessary, and add 1 mL of dilute hydrochloric acid (1 + 19) and 1 mL of barium chloride reagent solution. Allow to stand for 10 minutes. Any turbidity developed should not exceed that produced when 0.04 mg of sulfate ion (SO_4) is treated as the sample.

8.10 *Heavy Metals (as Ag)* — To 60 mL of the Stock Solution cautiously add 15 mL of nitric acid. For the standard add 0.05 mg of silver ion (Ag) to 10 mL of the Stock Solution and cautiously add 15 mL of nitric acid. Evaporate both solutions to dryness over a low flame or on an electric hot plate. Dissolve each residue in about 20 mL of water, filter if necessary through a chloride-free filter, and dilute with water to 25 mL. Adjust the pH of the standard and sample solutions to between 3 and 4 (using a pH meter) with 1 N acetic acid or ammonium hydroxide (10% NH_3). Dilute each solution with water to 40 mL and stir. Add 10 mL of freshly prepared hydrogen sulfide water to each solution and stir again. Any color developed in the sample should not exceed that in the standard.

8.11 *Iron* — Neutralize 10 mL of the Stock Solution with hydrochloric acid, using phenolphthalein indicator solution, add 2 mL in excess, and dilute with water to 50 mL. Add 30 to 50 mg of ammonium peroxydisulfate crystals and 3 mL of ammonium thiocyanate reagent solution. Any red color developed should not exceed that produced when 0.01 mg of iron ion (Fe) is treated as the sample.

8.12 *Mercury* — To each of two thoroughly clean 125 mL conical flasks add 20 mL of water and 1 mL of 4% potassium permanganate solution. To one add 5.5 g of solid sample. To the other add 0.5 g of sample and 0.5 mg of mercury ion (Hg). To each flask slowly add 18 mL of hydrochloric acid, with constant swirling. Heat to boiling, allow to cool, and dilute to 100 mL. Determine mercury in 10 mL aliquots by the cold vapor (flameless) atomic absorption method using 1 mL of 10% hydroxylamine hydrochloride reagent solution and 2 mL of 10% stannous chloride reagent solution for the reduction. The peak obtained with the sample solution should not be larger than that from the standard mercury solution.

8.13 *Nickel* — Dilute 20 mL of the Stock Solution to 50 mL with water and neutralize with hydrochloric acid. Dilute to 85 mL and add ammonium hydroxide to make the solution barely basic (pH 8). Add 5 mL of bromine water and 5 mL of alcoholic 1% dimethylglyoxime solution. Any red color developed should not exceed that produced when 0.02 mg of nickel ion (Ni) is treated as the sample.

8.14 *Sodium* — Dilute 10 mL of the Stock Solution with water to 100 mL to form the Sample Solution. To prepare the Standard Solution, add 0.5 mg of sodium ion (Na) to 10 mL of the Stock Solution and dilute with water to 100 mL.

8.14.1 Using flame emission spectroscopy, observe the emission of the Standard Solution at the 589 nm sodium line. Observe the emission of the Sample Solution at the 589 nm sodium line and also at a wavelength of 580 nm. The difference between the intensities observed for the Sample Solution at 580 nm and 589 nm should not exceed the difference observed at 589 nm between the Sample Solution and the Standard Solution (see SEMI C1, Section 3.7, Flame Emission Spectroscopy).

SEMI C40-0699
SPECIFICATION FOR POTASSIUM HYDROXIDE, 45% SOLUTION

This specification was technically approved by the Global Process Chemicals Committee and is the direct responsibility of the North American Process Chemicals Committee. Current edition approved by the North American Regional Standards Committee on April 23, 1999. Initially available on SEMI OnLine May 1999; to be published June 1999.

1 Purpose

1.1 The purpose of this document is to standardize requirements for 45% potassium hydroxide solution used in the semiconductor industry and testing procedures to support those standards. Test methods have been shown to give statistically valid results. This document also provides guidelines for grades of potassium hydroxide, 45% solution for which a need has been identified. In the case of the guidelines, the test methods may not have been statistically validated yet.

2 Scope

2.1 The scope of this document is all grades of 45% potassium hydroxide solution used in the semiconductor industry.

3 Limitations

3.1 None.

4 Referenced Documents

SEMI C1 — Specifications for Reagents

5 Terminology

5.1 None.

6 Physical Property (for information only)

6.1 Not applicable.

7 Requirements

7.1 The requirements for 45% potassium hydroxide solution for Grade 1 are listed in Table 1.

8 Grade 1 Procedures

NOTE 1: Each laboratory is responsible for verifying the validity of the method within its own operation.

8.1 *Assay* — Accurately weigh 70 to 80 g of sample in a closed weighing bottle. Transfer to a 500 mL volumetric flask, add in carbon dioxide-free water, cool to 25°C, dilute to the mark with carbon dioxide-free water, and mix thoroughly. Transfer 25.0 mL of this solution to a 500 mL glass-stoppered flask, dilute with 175 mL of carbon dioxide-free water, add 5 mL of barium chloride reagent solution, shake and allow to stand for five minutes. Add 0.15 mL of phenolphthalein indicator solution and titrate with standardized 1 N hydrochloric acid. (Save this solution for the potassium carbonate test.)

$$\%\text{Assay} = \frac{\text{mL} \times \text{N of HCl} \times 112.2}{\text{Weight of Sample (g)}}$$

8.2 *Potassium Carbonate (K_2CO_3)* — To the above titrated solution, add 0. 15 mL of methyl orange indicator and continue the titration with 1 N hydrochloric acid, making sure that no insoluble carbonate remains. The additional hydrochloric acid is equivalent to that consumed by the potassium carbonate.

$$\%\ K_2CO_3 = \frac{\text{mL} \times \text{N of HCl} \times 138.2}{\text{Weight of Sample (g)}}$$

8.3 *Ammonium Hydroxide Precipitate* — Weigh 40 g of sample into a 250 mL beaker and dissolve in about 100 mL of water.

8.3.1 Cautiously add 26 mL of sulfuric acid to 30 mL of water in a 150 mL glass beaker, cool; then cautiously add the mixture to the solution of the sample, and evaporate to dense fumes. Cool, dissolve the residue in 130 mL of hot water, and add ammonium hydroxide until the solution is just basic to methyl red.

8.3.2 Heat to boiling, filter, wash with hot water and ignite. The weight of the residue should not exceed 2 mg.

8.4 *Insoluble Matter* — Dilute 100 g of sample in 250 mL of carbon dioxide-free water in a 500 mL stoppered flask and cool to 25°C. The solution should be clear and colorless. Filter through a tared, medium porosity filtering crucible and wash thoroughly with hot water. Dry the crucible at 105°C for 1 hour, cool and weigh the residue. The weight of the residue should not exceed 5.0 mg.

8.5 *Stock Solution for Sections 8.6 through 8.13* — Add 100 g of sample to 250 mL of carbon dioxide-free water and dilute with such water to 500 mL. One mL contains 0.20 g of sample. Store in a plastic container.

8.6 *Nitrogen Compounds (as N)* — Dilute 20 mL of the stock solution with 50 mL of water in a flask connected through a spray trap to a condenser, the end of which dips beneath the surface of 10 mL of 0.1 N hydrochloric acid. For the standard, take 50 mL of water in a similar flask, and add 10 mL of the stock solution and 1 mL of the nitrogen standard solution (0.01mg N/mL). To each flask add 0.5 g of aluminum wire in small pieces, allow to stand for 1 hour, and slowly distill to about 35 mL. To each distillate add 2 mL of freshly boiled 10% sodium hydroxide reagent solution, dilute with water to 50, add 2 mL of Nessler reagent, and mix. Any color in the solution of the sample should not exceed that in the standard.

8.7 *Chloride* — Dilute l0 mL of the stock solution with water to 50 mL. Filter, if necessary, through a chloride-free filter. To 10 mL of this solution, add 5 mL of water, 2 mL of nitric acid, and 1 mL of silver nitrate reagent solution. Any turbidity developed should not exceed that produced by 0.02 mg of chloride (CI) ion in an equal volume of solution containing the quantities of reagent used in the test.

8.8 *Phosphate* — To 50 mL of the stock solution, add 15 mL of hydrochloric acid and evaporate to dryness on a steam bath. Dissolve the residue in 25 mL of 0.5 N sulfuric acid. Add 1 mL of ammonium molybdate reagent solution and l mL of p-(methylamino)phenol sulfate reagent solution. Allow the solution to stand for 2 hours at room temperature. Any blue color developed should not exceed that produced when 0.02 mg of phosphate (PO_4) ion is treated as the sample.

8.9 *Sulfate* — To 20 mL of the stock solution, add 5 mL of hydrochloric acid and evaporate to dryness on a steam bath. Dissolve the residue in 20 mL of water and evaporate again to dryness. Dissolve the residue in 20 mL of water, filter if necessary, and add 1 mL of dilute hydrochloric acid (1+19) and 1 mL of barium chloride reagent solution. Allow to stand for 10 minutes. Any turbidity developed should not exceed that produced when 0.04 mg of sulfate (SO_4) ion is treated as the sample.

8.10 *Heavy Metals (as Ag)* — To 60 mL of the stock solution cautiously add 15 mL of nitric acid. For the standard add 0.05 mg of silver ion (Ag) to 10 mL of the stock solution and cautiously add 15 mL of nitric acid. Evaporate both solutions to dryness over a low flame or on an electric hot plate. Dissolve each residue in about 20 mL of water, filter if necessary through a chloride-free filter, and dilute with water to 25 mL. Adjust the pH of the standard and sample solutions to between 3 and 4 (using a pH meter) with 1 N acetic acid or ammonium hydroxide (10% NH_3). Dilute each solution with water to 40 mL and stir. Add 10 mL of freshly prepared hydrogen sulfide water to each solution and stir again. Any color developed in the sample should not exceed that in the standard.

8.11 *Iron* — Neutralize l0 mL of the stock solution with hydrochloric acid, using a phenolphthalein indicator solution, add 2 mL of HCI in excess, and dilute with water to 50 mL. Add 30 to 50 mg of ammonium peroxydisulfate crystals and 3 mL of ammonium thiocyanate reagent solution. Any red color developed should not exceed that produced when 0.01 mg of iron (Fe) ion is treated as the sample.

8.12 *Nickel* — Dilute 20 mL of the stock solution to 50 mL with water and neutralize with hydrochloric acid using a pH meter. Dilute to 85 mL with water and add ammonium hydroxide to make the solution barely basic (pH 8). Add 5 mL of bromine water and 5 mL of alcoholic 1% dimethylgy1oxime solution. Any red color developed should not exceed that produced when 0.02 mg of nickel (Ni) ion is treated as the sample.

8.13 *Sodium* — Dilute 10 mL of the stock solution with water to 100 mL to form the sample solution. To prepare the standard solution, add 0.6 mg of sodium (Na) ion to 10 mL of the stock solution and dilute with water to 100 mL.

8.13.1 Using flame emission spectroscopy, observe the emission of the standard solution at the 589 nm sodium line. Observe the emission of the sample solution at the 589 nm sodium line and also at a wavelength of 580 nm. The difference between the intensities observed for the sample solution at 580 nm and 589 nm should not exceed the difference observed at 589 nm between the sample solution and standard solution (see SEMI Cl, Section 3.7, Flame Emission Spectroscopy).

SEMI C41-1101
SPECIFICATIONS AND GUIDELINES FOR 2-PROPANOL

These specifications and guidelines were technically approved by the Global Process Chemicals Committee and are the direct responsibility of the North American Process Chemicals Committee. Current edition approved by the North American Regional Standards Committee on August 27, 2001. Initially available at www.semi.org September 2001; to be published November 2001. This document replaces SEMI C1.15, C7.7, C8.7, and C11.7 in their entirety. Originally published in 1978, 1990, 1992, and 1998 respectively. Previously published March 2001.

1 Purpose

1.1 The purpose of this document is to standardize requirements for 2-propanol used in the semiconductor industry and testing procedures to support those standards. Test methods have been shown to give statistically valid results. This document also provides guidelines for grades of 2-propanol for which a need has been identified. In the case of the guidelines, the test methods may not have been statistically validated yet.

2 Scope

2.1 The scope of this document is all grades of 2-propanol used in the semiconductor industry.

2.2 The VLSI grade purity level is typically required by semiconductor devices with geometries of 0.8–1.2 microns.

2.3 These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 None.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI C1 — Specifications for Reagents

4.2 *ASTM Standards*[1]

ASTM D5127 — Standard Guide for Ultra Pure Water Used in the Electronics and Semiconductor Industry

NOTE 1: Unless otherwise indicated, all documents cited shall be the latest published versions.

5 Terminology

5.1 None.

6 Physical Property (for information only)

Density at 25°C	0.78 g/mL
Boiling Point	82.3°C

7 Requirements

7.1 The requirements for 2-propanol for Grades 1 and 2, VLSI Grade, and Tiers B and C are listed in Table 1.

8 Grade 1 Procedures

NOTE 2: Due to the uncertainty of acid concentration in the liquid residue the final concentration can be estimated to be approximately 2% (v/v). Standard calibration solutions are to use this same acid concentration.

NOTE 3: Each laboratory is responsible for verifying the validity of the method within its own operation.

8.1 *Assay* — Analyze the sample by gas chromatography (see SEMI C1, Section 3.1, Guidelines for Assay by Wide Bore Column Gas Chromatography). The parameters cited have given satisfactory results.

Column: 30 meter × 530 micron I.D. fused silica capillary, coated with 5 micron film of DB-Wax or equivalent (100% methyl silicone which has been surface bonded and cross linked).

Column Temperature: 40°C isothermal for 5 minutes, then programmed to 200°C at 10°C/min.

Injector Temperature:	150°C
Detector Temperature:	250°C
Sample Size:	0.2 µL splitless
Carrier Gas:	Helium at 3 mL/min
Detector:	Thermal Conductivity
Approximate Retention Times (min):	
Acetone	4.5
2-Propanol	5.0

8.2 *Color* — Dilute 2.0 mL of platinum-cobalt stock solution (APHA No. 500) to 100 mL with water.

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, Pennsylvania 19428-2959, USA. Telephone: 610.832.9585, Fax: 610.832.9555 Website: www.astm.org

Compare this standard (APHA No. 10) with 100 mL of sample in Nessler tubes. View vertically over a white background. The sample must be no darker than the standard.

8.3 *Acidity* — To 25 mL of water in a glass-stoppered flask, add 10 mL of sample and 0.1 mL of phenolphthalein indicator solution. Add 0.01 N sodium hydroxide until a slight pink color persists after shaking for one-half minute. Add 64 mL (50 g) of the sample, mix well, and titrate with 0.01 N sodium hydroxide until the pink color is reproduced. Not more than 1.0 mL of the sodium hydroxide solution should be required.

8.4 *Alkalinity* — Add 128 mL (100 g) of sample to 25 mL of water and mix well. Add 0.05 mL of methyl red indicator solution. Titrate with 0.01 N hydrochloric acid until a slight pink color is produced. Not more than 1.0 mL of the hydrochloric acid should be required.

8.5 *Residue after Evaporation* — Evaporate 256 mL (200 g) of sample to dryness. Dry at 105°C for 30 minutes, cool in a desiccator, and weigh (see SEMI C1, Section 3.3, Determination of Residue After Evaporation).

8.6 *Water* — Add 25 mL of methanol to a dry titration flask and add Karl Fischer (KF) reagent to a visually or electrometrically determined endpoint that persists for 30 seconds. Add 25 mL (20 g) of sample, taking care to protect the sample and contents of the flask from moisture. Stir vigorously and titrate with Karl Fischer reagent to the same endpoint.

$$\%\ \text{Water}\ (H_2O) = \frac{\text{mL KF reagent} \times \text{KF factor}\left(\text{g } H_2O/\text{mL}\right) \times 100}{\text{Weight of sample}\ (\text{g})}$$

8.7 *Solubility in Water* — Mix 10 mL of sample with 40 mL of water. Allow to stand 1 hour. The solution should be as clear as an equal volume of water.

8.8 *Chloride* — To 64 mL (50 g) of sample, add 10 mL of sodium carbonate reagent solution and evaporate to dryness on a steam bath in a hood. Dissolve the residue in 10 mL of water, add 1 mL of nitric acid and dilute to 20 mL with water. Add 1 mL of silver nitrate reagent solution. Any turbidity produced should be no greater than that produced when 0.01 mg of chloride ion (Cl) is treated as the sample.

8.9 *Phosphate* — To 26 mL (20 g) of sample, add 10 mL of sodium carbonate reagent solution and evaporate to dryness on a steam bath in a hood. Dissolve the residue in 25 mL of 0.5 N sulfuric acid. Add 1 mL of ammonium molybdate reagent solution and 1 mL of p-(methylamino)phenol sulfate reagent solution. Allow to stand at room temperature for 2 hours. Any blue color produced should be no greater than that produced when 0.01 mg of phosphate ion (PO_4) is treated like the sample.

8.10 *Arsenic and Antimony (as As)* — Evaporate 256 mL (200 g) of sample in a 400 mL beaker to a small volume in a hood. Add 50 mL of water and again evaporate to a small volume. Repeat the evaporation with water addition. Do not allow to go to dryness. Add 5 mL of nitric acid and 5 mL of sulfuric acid and evaporate to dense fumes of sulfur trioxide. Cool, cautiously add 10 mL of water, and again evaporate to dense fumes of sulfur trioxide. Cool, and cautiously wash into a generator flask with water to make a volume of 35 mL. Proceed as described in the General Method for Arsenic (and Antimony) under SEMI C1, Section 3.4.5, starting with the sentence which begins, “Swirl the flask....” Any red color in the silver diethyldithiocarbamate solution of the sample should be no greater than that of the standard containing 0.002 mg of arsenic (As).

8.11 *Trace Metal Analysis*

8.11.1 *Boron* — To 128 mL (100 g) of sample, add 0.10 mL of 10% sodium hydroxide, and evaporate to dryness in a nitrogen atmosphere using a covered chamber such as a Thiers assembly or equivalent. Dissolve the residue with 2 mL of water and 0.10 mL of hydrochloric acid. Transfer to a test tube, cool in an ice bath, and add 10 mL of sulfuric acid. Add 10 mL of carminic acid solution and remove from the ice bath. Allow to stand for 45 minutes. Prepare a standard containing 0.001 mg of boron treated exactly as the sample. Run a complete blank determination on 2 mL of water. Measure the absorbances of the sample and standard against the blank at 585 nm using 5.00 cm cells. The absorbance of the sample solution should be no greater than that of the standard.

8.11.1.1 *Carminic Acid Solution* — Dissolve 0.05 g of carminic acid in 100 mL of sulfuric acid and shake until dissolution is complete.

8.11.1.2 *Boron Standard Solution* — Dissolve 0.572 g of boric acid in water in a 1000 mL volumetric flask. Dilute to the mark with water. Dilute 10.0 mL of this solution with water to the mark in a 100 mL volumetric flask. (1 mL = 0.01 mg boron.)

8.11.2 *Gold (Au)* — Analyze by graphite atomic absorption using the manufacturer's recommended procedure. This technique has been shown to give satisfactory results using a 1:4 dilution and Zeeman background correction. Each laboratory must determine the appropriate dilution and background correction for their instrument to meet the specification limit.

8.11.3 The following method has given satisfactory results in determining trace metal impurities at the value specified for each of the following trace metals: aluminum (Al), calcium (Ca), chromium (Cr), copper (Cu), iron (Fe), lead (Pb), magnesium (Mg), manganese (Mn), nickel (Ni), potassium (K), sodium (Na), tin (Sn), titanium (Ti), and zinc (Zn). Alternate methods may be used as long as appropriate studies demonstrate recovery between 75–125% of a known sample spike for half of the value of each specified item.

8.11.4 *Special Reagents*

8.11.4.1 *Hydrochloric Acid, Ultra Pure* — Use hydrochloric acid specified for ultra low metal ion content.

8.11.4.2 *2% (v/v) Hydrochloric Acid Solution* — Dilute 20 mL of ultra pure 12 M hydrochloric acid to 1 L using water meeting the criteria for Type E1.1 in ASTM D5127.

8.11.5 *Sample Preparation*

8.11.5.1 *Tin* — To 100 g (128 mL) sample in a PTFE dish add 1 mL of 1% oxalic acid solution. Slowly evaporate to about 1 mL. Dissolve the residue in 10% hydrochloric acid and transfer to a 10 mL volumetric flask using 10% hydrochloric acid. Analyze by plasma emission spectrometry using matrix-matched standards.

8.11.5.2 *All Other Elements* — In a clean environment, place 250 g of solvent in a PTFE dish. Slowly evaporate on a hot plate avoiding loss of sample by effervescence or spattering until approximately 1 mL of liquid remains. Take up liquid and all visible residue (from walls of dish) with 1 mL ultra pure, 12 M hydrochloric acid and continue heating until approximately 0.5 mL of liquid remains. No undissolved particulate matter should be observed. Otherwise repeat the addition of hydrochloric acid until all particulate matter is dissolved. Transfer quantitatively to a 50 mL volumetric flask using 2% (v/v) hydrochloric acid and adjust liquid level to mark. Prepare a reagent blank using the same reagents and in the same manner as for the sample concentration.

8.11.6 *Analysis*

8.11.6.1 Using the prepared sample and reagent blank, analyze group I elements potassium (K) and sodium (Na) by atomic absorption spectroscopy and all other elements by plasma emission spectroscopy. Apply, if necessary, a reagent blank correction to the final determined value of the sample.

9 Grade 2 Procedures

NOTE 4: Each laboratory is responsible for verifying the validity of the method within its own operation.

9.1 *Non-Metal Impurities* — See Section 8, which contains procedures for the following tests:

Assay

Water

Color (APHA)

Chloride

Phosphate

Arsenic and Antimony (as As)

Boron

9.2 *Trace Metals Analysis*

9.2.1 The following method has given satisfactory results in determining metal ion impurities at the values specified for each of the following metals: aluminum (Al), barium (Ba), beryllium (Be), bismuth (Bi), calcium (Ca), chromium (Cr), cobalt (Co), copper (Cu), gallium (Ga), germanium (Ge), gold (Au), iron (Fe), lead (Pb), lithium (Li), magnesium (Mg), manganese (Mn), molybdenum (Mo), nickel (Ni), niobium (Nb), potassium (K), silver (Ag), sodium (Na), strontium (Sr), tantalum (Ta), tin (Sn), titanium (Ti), vanadium (V), zinc (Zn), and zirconium (Zr). Alternate methods may be used as long as appropriate studies demonstrate a recovery between 75–125% of a known sample spike for half of the value of each specified element.

9.2.2 *Special Reagents*

9.2.2.1 *Nitric Acid, Ultra Pure* — Use nitric acid specified for low metal ion content.

9.2.2.2 *1% Nitric Acid Solution* — Dilute 10 mL of ultrapure nitric acid to 1 L using water meeting the criteria for Type E1.1 in ASTM D5127.

9.2.2.3 *Water* — The water used for all the dilution, calibration and standards should meet at a minimum the criteria for Type E1.1 in ASTM D5127 in regard to cation analysis.

9.2.2.4 *Indium Internal Standard* — Make up an indium internal standard solution to a concentration of 20 mg/mL (ppm) from an appropriate concentrated indium standard solution.

9.2.2.5 *Mannitol Powder* — Mannitol powder, reagent grade (ACS)

9.2.2.6 *5% Mannitol Solution* — Prepare a 5% (by weight), dissolve and dilute 5 g of reagent grade Mannitol powder (ACS) to 100 g using water meeting the criteria for Type E1.1 in ASTM D5127.

9.2.3 *Sample Preparation*

9.2.3.1 *All Elements* — In a clean environment, place 200 g of sample into a PTFE dish. Add 5 mL of the 5% Mannitol solution and 100 mL of the 1% nitric acid solution. Slowly evaporate on a hot plate to dryness avoiding loss of sample by effervescence or spattering until 1 to 2 mL remain. Dissolve the residue with 5 mL of the 1% nitric acid solution by heating on a hot plate at low temperature for several minutes. Cool to room temperature, dilute to 50 mL with 1% nitric acid, add 50 mL of the indium internal standard, mix well. Run a reagent blank.

9.2.4 *Analysis*

9.2.4.1 Using the prepared solutions and blanks, analyze potassium, calcium and iron by graphite furnace atomic absorption (GFAA) and the remaining elements by inductively coupled plasma mass spectrometry (ICP/MS). For calibration, the standards are made up with the 1% nitric acid solution and a final concentration of 20 ng/g of the indium internal standard.

10 Grade 3 Procedures

10.1 This section does not apply to this chemical.

11 Grade 4 Procedures

11.1 This section does not apply to this chemical.

12 Grade 5 Procedures

12.1 This section does not apply to this chemical.

13 VLSI Grade Procedures

13.1 Specific procedures for this grade do not exist. Refer to Sections 8 and 9 for available procedures.

14 Tier A Procedures

14.1 This section does not apply to this chemical.

15 Tier B Procedures

15.1 Standardized test methods are being developed for all parameters at the purity levels indicated. Until standardized test methods are published, test methodology shall be determined by user and producer. The Process Chemicals Committee considers a test method to be valid only if there is a documented recovery study showing a recovery of 75–125%. Recovery is for a known sample spike at 50% of the specified level.

16 Tier C Procedures

16.1 Standardized test methods are being developed for all parameters at the purity levels indicated. The Process Chemicals Committee considers a test method to be valid if there is a documented recovery study showing a recovery of 75–125%. Recovery is for a known sample spike at 50% of the specified level.

17 Tier D Procedures

17.1 This section does not apply to this chemical.

Table 1 Impurity Limits and Other Requirements for 2-Propanol

SEMI C42-0699
SPECIFICATION FOR SODIUM HYDROXIDE PELLETS

This specification was technically approved by the Global Process Chemicals Committee and is the direct responsibility of the North American Process Chemicals Committee. Current edition approved by the North American Regional Standards Committee on April 23, 1999. Initially available on SEMI OnLine May 1999; to be published June 1999. This document replaces SEMI C1.22 in its entirety. Originally published in 1978.

1 Purpose

1.1 The purpose of this document is to standardize requirements for sodium hydroxide pellets used in the semiconductor industry and testing procedures to support those standards. Test methods have been shown to give statistically valid results. This document also provides guidelines for grades of sodium hydroxide pellets for which a need has been identified. In the case of the guidelines, the test methods may not have been statistically validated yet.

2 Scope

2.1 The scope of this document is all grades of sodium hydroxide pellets used in the semiconductor industry.

3 Limitations

3.1 None.

4 Referenced Documents

SEMI C1 — Specifications for Reagents

5 Terminology

5.1 None.

6 Physical Property (for information only)

6.1 Not applicable.

7 Requirements

7.1 The requirements for sodium hydroxide pellets for Grade 1 are listed in Table 1.

8 Grade 1 Procedures

8.1 *Assay* — Weigh accurately 35 to 40 g of sample in a closed weighing bottle. Transfer to a 500 mL volumetric flask, dissolve with carbon dioxide-free water, cool to 25°C, dilute to the mark with carbon dioxide-free water, and mix thoroughly. Transfer 25 mL of this solution to a 500 mL glass-stoppered flask, dilute with 175 mL of carbon dioxide-free water, add 5 mL of barium chloride reagent solution, shake, and allow to stand for five minutes. Add 0.15 mL of phenolphthalein indicator solution and titrate with 1 N hydrochloric acid. (Save this solution for the sodium carbonate test.)

$$\%\text{Assay} = \frac{\text{mL} \times \text{N of HCl} \times 80.00}{\text{Weight of sample (g)}}$$

8.2 *Sodium Carbonate (Na_2CO_3)* — To the above titrated solution, add 0.15 mL of methyl orange indicator and continue the titration with 1 N hydrochloric acid, making sure that no insoluble carbonate remains. The additional hydrochloric acid is equivalent to that consumed by the sodium carbonate.

$$\%\ Na_2CO_3 = \frac{\text{mL} \times \text{N of HCl} \times 106.00}{\text{Weight of sample (g)}}$$

8.3 *Ammonium Hydroxide Precipitate* — Weigh 10 g of sample and dissolve in about 100 mL of water. Cautiously add 15 mL of sulfuric acid to 15 mL of water, cool; then cautiously add the mixture to the solution of the sample, and evaporate to dense fumes. Cool, dissolve the residue in 130 mL of hot water, and add ammonium hydroxide until the solution is just basic to methyl red. Heat to boiling, filter, wash with hot water, and ignite. The weight of the residue should not exceed 2 mg.

8.4 *Insoluble Matter* — Dissolve 50 g of sample in 250 mL of carbon dioxide-free water in a 500 mL stoppered flask and cool to 25° C. The solution should be clear and colorless. Filter through a tared, medium-porosity filtering crucible and wash thoroughly with hot water. Dry at 105° C for 1 hour, cool, and weigh the residue. The result of the residue should not exceed 2.5 mg.

8.5 *Stock Solution for 8.6-8.11, 8.13-8.14* — Dissolve 50 g of sample in 250 mL of carbon dioxide-free water and dilute with such water to 500 mL. One mL contains 0.10 g of sample. Store in a plastic container.

8.6 *Nitrogen Compounds (as N)* — Dilute 20 mL of the Stock Solution with 50 mL of water in a flask connected through a spray trap to a condenser, the end of which dips beneath the surface of 10 mL of 0.1 N hydrochloric acid. For the standard, take 50 mL of water in a similar flask, and add 10 mL of the Stock Solution and 1 mL of the nitrogen standard solution. To each flask add 0.5 g of aluminum wire in small pieces, allow to stand for 1 hour, and slowly distill about 35 mL. To each distillate, add 2 mL of freshly boiled 10% sodium hydroxide reagent solution, dilute with water to 50 mL, and add 2 mL of Nessler reagent. Any color in the solution of the sample should not exceed that in the standard.

8.7 *Chloride* — Dilute 10 mL of the Stock Solution with water to 100 mL. Filter, if necessary, through a chloride-free filter. To 20 mL of this solution add 5 mL of water, 1 mL of nitric acid and 1 mL of silver nitrate reagent solution. Any turbidity developed should not exceed that produced by 0.01 mg of chloride ion (Cl) in an equal volume of solution containing the quantities of reagents used in the test.

8.8 *Phosphate* — To 40 mL of Stock Solution, add 10 mL of hydrochloric acid and evaporate to dryness on a steam bath. Dissolve the residue in 25 mL of 0.5 N sulfuric acid. Add 1 mL of ammonium molybdate reagent solution and 1 mL of p-(methylamino)phenol sulfate reagent solution. Allow to stand for 2 hours at room temperature. Any blue color developed should not exceed that produced when 0.02 mg of phosphate ion (PO_4) is treated as the sample.

8.9 *Sulfate* — To 20 mL of the Stock Solution, add 5 mL of hydrochloric acid and evaporate to dryness on a steam bath. Dissolve the residue in 20 mL of water and evaporate again to dryness. Dissolve the residue in 20 mL of water, filter if necessary and add 1 mL of dilute hydrochloric acid (1 + 19) and 1 mL of barium chloride reagent solution. Allow to stand for 10 minutes. Any turbidity developed should not exceed that produced when 0.04 mg of sulfate ion (SO_4) is treated as the sample.

8.10 *Heavy Metals (as Ag)* — To 60 mL of the Stock Solution, cautiously add 20 mL of nitric acid. For the standard, add 0.05 mg of silver ion (Ag) to 10 mL of the Stock Solution and cautiously add 20 mL of nitric acid. Evaporate both solutions to dryness over a low flame or an electric hot plate. Dissolve each residue in about 20 mL of water, filter if necessary through a chloride-free filter, and dilute with water to 25 mL. Adjust the pH of the standard and sample solutions to between 3 and 4 (using a pH meter) with 1 N acetic acid or ammonium hydroxide (10% NH_3). Dilute each solution with water to 40 mL and stir. Add 10 mL of freshly prepared hydrogen sulfide water to each solution and stir again. Any color developed in the sample should not exceed that in the standard.

8.11 *Iron* — Neutralize 10 mL of the Stock Solution with hydrochloric acid using phenolphthalein indicator solution, add 2 mL in excess, and dilute with water to 50 mL. Add 30 to 50 mg of ammonium peroxydisulfate crystals and 3 mL of ammonium theiocyanate reagent solution. Any red color developed should not exceed that produced when 0.01 mg of iron ion (Fe) is treated as the sample.

8.12 *Mercury* — To each of two thoroughly clean 125 mL conical flasks add 20 mL of water and 1 mL of 4% potassium permanganate solution. To one add 5.5 g of sample. To the other add 0.5 g of sample and 0.5 mg of mercury ion (Hg). To each flask slowly add 18 mL of hydrochloric acid, with constant swirling. Heat to boiling, allow to cool, and dilute to 100 mL. Determine mercury in 10 mL aliquots by the cold vapor (flameless) atomic absorption method using 1 mL of 10% hydroxylamine hydrochloride reagent solution and 2 mL of 10% stannous chloride reagent solution for the reduction. The peak obtained with the sample solution should not be larger than that of the standard mercury solution.

8.13 *Nickel* — Dilute 20 mL of the Stock Solution to 50 mL with water and neutralize with hydrochloric acid using a pH meter. Dilute to 85 mL and add ammonium hydroxide to make the solution just basic (pH 8). Add 5 mL of bromine water, 5 mL of alcoholic 1% dimethylgyloxime solution in alcohol, and 5 mL of 10% sodium hydroxide reagent solution. Any red color developed should not exceed that produced when 0.02 mg of nickel ion (Ni) is treated as the sample.

8.14 *Potassium* — Dilute 10 mL of the Stock Solution with water to 100 mL to form the Sample Solution. To prepare the Standard Solution, add 0.2 mg of potassium ion (K) to 10 mL of the Stock Solution and dilute with water to 100 mL.

8.14.1 Using flame emission spectroscopy, observe the emission of the Standard Solution at the 767 nm potassium line. Observe the emission of the Sample Solution at the 767 nm potassium line and also at a wavelength of 750 nm. The difference between the intensities observed for the Sample Solution at 767 nm and 750 nm should not exceed the difference observed at 767 nm between the Sample Solution and Standard Solution (see SEMI C1, Section 3.7, Flame Emission Spectroscopy).

Iron (Fe)	10 ppm max
Mercury (Hg)	0.1 ppm max
Nickel (Ni)	10 ppm max
Potassium (K)	0.02% max

SEMI C43-0699
SPECIFICATION FOR SODIUM HYDROXIDE, 50% SOLUTION

This specification was technically approved by the Global Process Chemicals Committee and is the direct responsibility of the North American Process Chemicals Committee. Current edition approved by the North American Regional Standards Committee on April 23, 1999. Initially available on SEMI OnLine May 1999; to be published June 1999.

1 Purpose

1.1 The purpose of this document is to standardize requirements for 50% sodium hydroxide solution used in the semiconductor industry and testing procedures to support those standards. Test methods have been shown to give statistically valid results. This document also provides guidelines for grades of 50% sodium hydroxide solution for which a need has been identified. In the case of the guidelines, the test methods may not have been statistically validated yet.

2 Scope

2.1 The scope of this document is all grades of 50% sodium hydroxide solution used in the semiconductor industry.

3 Limitations

3.1 None.

4 Referenced Documents

SEMI C1 — Specifications for Reagents

5 Terminology

5.1 None.

6 Physical Property (for information only)

6.1 Not applicable.

7 Requirements

7.1 The requirements for 50% sodium hydroxide solution for Grade 1 are listed in Table 1.

8 Grade 1 Procedures

NOTE 1: Each laboratory is responsible for verifying the validity of the method within its own operation.

8.1 *Assay* — Accurately weigh 70 to 80 g of sample in a closed weighing bottle. Transfer to a 500 mL volumetric flask, dilute in carbon dioxide-free water, cool to 25°C, dilute to the mark with carbon dioxide-free water, and mix thoroughly. Transfer 25.0 mL of this solution to a 500 mL glass-stoppered flask, dilute with 175 mL of carbon dioxide-free water, add 5 mL of barium chloride reagent solution, shake and allow to stand for five minutes. Add 0.15 mL of phenolphthalein indicator solution and titrate with standardized 1 N hydrochloric acid. (Save this solution for the sodium carbonate test.)

$$\%\ \text{Assay} = \frac{\text{mL} \times \text{N of HCl} \times 80.00}{\text{Weight of Sample (g)}}$$

8.2 *Sodium Carbonate* — To the above titrated solution, add 0.15 mL of methyl orange indicator and continue the titration with 1 N hydrochloric acid, making sure that no insoluble carbonate remains. The additional hydrochloric acid is equivalent to that consumed by the sodium carbonate.

$$\%\ Na_2CO_3 = \frac{\text{mL} \times \text{N of HCl} \times 106.0}{\text{Weight of Sample (g)}}$$

8.3 *Ammonium Hydroxide Precipitate* — Weigh 20 g of sample into 250 mL beaker and dissolve in about 100 mL of water.

8.3.1 Cautiously add 15 mL of sulfuric acid to 15 mL of water in a 100 mL glass beaker, cool; then cautiously add the mixture to the solution of the sample, and evaporate to dense fumes. Cool, dissolve the residue in 130 mL of hot water, and add ammonium hydroxide until the solution is just basic to methyl red.

8.3.2 Heat to boiling, filter, wash with hot water and ignite. The weight of the residue should not exceed 2 mg.

8.4 *Insoluble Matter* — Dilute 50 g of sample in 250 mL of carbon dioxide-free water in a 500 mL stoppered flask and cool to 25°C. The solution should be clear and colorless. Filter through a tared, medium porosity filtering crucible and wash thoroughly with hot water. Dry the crucible at 105°C for 1 hour, cool and weigh the residue. The weight of the residue should not exceed 2.5 mg.

8.5 *Stock Solution for Sections 8.6 through 8.13* — Add 50 g of sample to 250 mL of carbon dioxide-free water and dilute with such water to 500 mL. One mL contains 0.10 g of sample. Store in a plastic container.

8.6 *Nitrogen Compounds (as N)* — Dilute 30 mL of the stock solution with 50 mL of water in a flask connected through a spray trap to a condenser, the end of which dips beneath the surface of 10 mL of 0.1 N hydrochloric acid. For the standard, take 50 mL of water in a similar flask, and add 10 mL of the stock solution and 1 mL of the nitrogen standard solution (0.010mg N/ml). To each flask add 0.5 g of aluminum wire in small pieces, and allow the solution to stand for 1 hour. Slowly distill to about 35 mL of solution. To each distillate add 2 mL of freshly boiled 10% sodium hydroxide reagent solution, dilute with water to 50 mL and add 2 mL of Nessler reagent. Any color in the solution of the sample should not exceed that in the standard.

8.7 *Chloride* — Dilute l0 mL of the stock solution with water to 100 mL. Filter, if necessary, through a chloride-free filter. To 25 mL of this solution, add 5 mL of water, 1 mL of nitric acid, and 1 mL of silver nitrate reagent solution. Any turbidity developed should not exceed that produced by 0.01 mg of chloride (CI) ion in an equal volume of solution containing the quantities of reagent used in the test

8.8 *Phosphate* — To 40 mL of the stock solution, add 10 mL of hydrochloric acid and evaporate to dryness on a steam bath. Dissolve the residue in 25 mL of 0.5 N sulfuric acid. Add 1 mL of ammonium molybdate reagent solution and l mL of p-(methylamino)phenol sulfate reagent solution. Allow the solution to stand for 2 hours at room temperature. Any blue color developed should not exceed that produced when 0.02 mg of phosphate (PO_4) ion is treated as the sample.

8.9 *Sulfate* — To 40 mL of the stock solution, add 5 mL of hydrochloric acid and evaporate to dryness on a steam bath. Dissolve the residue in 20 mL of water and evaporate again to dryness. Dissolve the residue in 20 mL of water, filter if necessary, and add 1 mL of dilute hydrochloric acid (1+19) and 1 mL of barium chloride reagent solution. Allow the solution to stand for 10 minutes. Any turbidity developed should not exceed that produced when 0.04 mg of sulfate (SO_4) ion is treated as the sample.

8.10 *Heavy Metals (as Ag)* — To 60 mL of the stock solution cautiously add 20 mL of nitric acid. For the standard add 0.05 mg of silver ion (Ag) to 10 mL of the stock solution and cautiously add 20 mL of nitric acid. Evaporate both solutions to dryness over a low flame or on an electric hot plate. Dissolve each residue in about 20 mL of water, filter if necessary through a chloride-free filter, and dilute with water to 25 mL. Adjust the pH of the standard and sample solutions to between 3 and 4 (using a pH meter) with 1 N acetic acid or ammonium hydroxide (10% NH_3). Dilute each solution with water to 40 mL and stir. Add 10 mL of freshly prepared hydrogen sulfide water to each solution and stir again. Any color developed in the sample should not exceed that in the standard.

8.11 *Iron* — Neutralize 20 mL of the stock solution with hydrochloric acid, using a phenolphthalein indicator solution, add 2 mL of HCI in excess, and dilute with water to 50 mL. Add 30 to 50 mg of ammonium peroxydisulfate crystals and 3 mL of ammonium thiocyanate reagent solution. Any red color developed should not exceed that produced when 0.01 mg of iron (Fe) ion is treated as the sample.

8.12 *Nickel* — Dilute 40 mL of the stock solution to 50 mL with water and neutralize with hydrochloric acid using a pH meter. Dilute to 85 mL with water and add ammonium hydroxide to make the solution barely basic (pH 8). Add 5 mL of bromine water and 5 mL of alcoholic 1% dimethylgy1oxime solution in alcohol, and 5 mL of 10% sodium hydroxide reagent solution. Any red color developed should not exceed that produced when 0.02 mg of nickel (Ni) ion is treated as the sample.

8.13 *Potassium* — Dilute 10 mL of the stock solution with water to 100 mL to form the sample solution. To prepare the standard solution, add 0.1 mg of potassium (K) ion to 10 mL of the stock solution and dilute with water to 100 mL.

8.13.1 Using flame emission spectroscopy, observe the emission of the standard solution at the 767 nm potassium line. Observe the emission of the sample solution at the 767 nm potassium line and also at a wavelength of 750 nm. The difference between the intensities observed for the Sample Solution at 767 nm and 750 nm should not exceed the difference observed at 767 nm between the sample solution and standard solution (see SEMI Cl, Section 3.7, Flame Emission Spectroscopy).

SEMI C44-0301
SPECIFICATIONS AND GUIDELINES FOR SULFURIC ACID

These specifications and guidelines were technically approved by the Global Process Chemicals Committee and are the direct responsibility of the North American Process Chemicals Committee. Current edition approved by the North American Regional Standards Committee on October 17, 1999. Initially available at www.semi.org February 2001; to be published March 2001. This document replaces SEMI C1.16, C7.8, C8.8, and C11.5 in their entirety. Originally published in 1978, 1990, 1992, and 1994 respectively; previously published October 2000.

1 Purpose

1.1 The purpose of this document is to standardize requirements for sulfuric acid used in the semiconductor industry and testing procedures to support those standards. Test methods have been shown to give statistically valid results. This document also provides guidelines for grades of sulfuric acid for which a need has been identified. In the case of the guidelines, the test methods may not have been statistically validated yet.

2 Scope

2.1 The scope of this document is all grades of sulfuric acid used in the semiconductor industry.

2.2 The VLSI grade purity level is typically required by semiconductor devices with geometries of 0.8–1.2 microns.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 None.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI C1 — Specifications for Reagents

4.2 *ASTM Standards*[1]

ASTM D5127 — Standard Guide for Ultra Pure Water Used in the Electronics and Semiconductor Industry

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 None.

6 Physical Property (for information only)

Density at 25°C	1.83 g/mL

7 Requirements

7.1 The requirements for sulfuric acid for Grades 1 and 2, VLSI Grade, and Tiers B and C are listed in Table 1.

8 Grade 1 Procedures

NOTE 2: Each laboratory is responsible for verifying the validity of the method within its own operation.

8.1 *Assay* — Accurately weigh 1 mL of sample in a small glass-stoppered conical flask. Cautiously add 30 mL of water, cool, add 0.1 mL of methyl orange indicator solution, and titrate with standardized 1.0 N sodium hydroxide to a red to yellow color change.

$$\%\text{Assay} = \frac{\text{mL} \times \text{N of NaOH} \times 4.904}{\text{Weight of sample (g)}}$$

8.2 *Color* — Dilute 2.0 mL of platinum-cobalt stock solution (APHA No. 500) to 100 mL with water. Compare this standard (APHA No. 10) with 100 mL of sample in Nessler tubes. View vertically over a white background. The sample must be no darker than the standard.

8.3 *Chloride* — Place 40 mL of water in each of two beakers. To one, add carefully 27 mL (50 g) of sample and to the other, 27 mL (50 g) of chloride-free sulfuric acid and 0.005 mg of chloride ion (Cl). Cool to room temperature and add 1 mL of nitric acid and 1 mL of silver nitrate reagent solution. Mix well; if necessary, make the volume of each solution identical by adding water. After 10 minutes, measure the turbidity of each solution using a suitable nephelometer. The turbidity in the sample should be no greater than the standard.

NOTE 3: Prepare chloride-free sulfuric acid in a hood by gently fuming sulfuric acid in a crucible or dish for at least 30

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, Pennsylvania 19428-2959, USA. Telephone: 610.832.9585, Fax: 610.832.9555. Website: www.astm.org

minutes. Cool and transfer to a tightly-capped glass bottle for storage.

8.4 *Nitrate* — Prepare the following solutions:

Sample Solution A:	Cautiously add 27 mL (50 g) of sample to 1.0 mL of water, dilute to 50 mL with brucine sulfate reagent solution and mix.
Control Solution B:	Cautiously add 27 mL (50 g) of sample to 1.0 mL of the standard nitrate solution containing 0.01 mg of nitrate ion (NO_3) per mL, dilute to 50 mL with brucine sulfate reagent solution and mix.
Blank Solution C:	Use 50 mL of brucine sulfate reagent solution.

8.4.1 Heat the three solutions in a preheated (boiling) water bath for 10 minutes. Cool rapidly in an ice bath to room temperature. Set a photometer at 410 nm and, using 1-cm cells, adjust the instrument to read zero absorbance with Blank Solution C in the light path, then determine the absorbance of Sample Solution A. Adjust the instrument to read zero absorbance with Sample Solution A in the light path and determine the absorbance of Control Solution B. The absorbance of Sample Solution A should be no greater than that Control Solution B.

8.5 *Phosphate* — Evaporate 11 mL (20 g) of sample to dryness in a platinum dish in a hood. Dissolve the residue in 25 mL of 0.5 N sulfuric acid. Add 1 mL of ammonium molybdate reagent solution and 1 mL p-(methylamino)phenol sulfate reagent solution. Allow to stand at room temperature for 2 hours. Any blue color produced should be no greater than that produced when 0.01 mg of phosphate ion (PO_4) is treated as the sample.

8.6 *Arsenic and Antimony (as As)* — To 109 mL (200 g) of sample in a beaker, add 5 mL of nitric acid and evaporate to about 10 mL in a hood. Cool. Cautiously add 10 mL of water, and again evaporate to about 5 mL. Cool, and cautiously wash into a generator flask with water to make a volume of 35 mL. Proceed as described in General Method for Arsenic (and Antimony) under SEMI C1, Section 3.4.5, starting with the first sentence which begins: “Swirl the flask...” Any red color in the silver diethyldithiocarbamate solution from the sample should be no greater than that of the standard containing 0.001 mg of arsenic (As).

8.7 *Trace Metal Analysis*

8.7.1 *Gold (Au)* — Analyze by graphite atomic absorption using the manufacturer's recommended procedure. This technique has been shown to give satisfactory results using a 1:4 dilution and Zeeman background correction. Each laboratory must determine the appropriate dilution and background correction for its instrument to meet the specification limit.

8.7.2 The following method has given satisfactory results in determining trace metal impurities at the value specified for each of the following trace metals: aluminum (Al), boron (B), calcium (Ca), chromium (Cr), copper (Cu), iron (Fe), lead (Pb), magnesium (Mg), manganese (Mn), nickel (Ni), potassium (K), sodium (Na), tin (Sn), titanium (Ti), and zinc (Zn). Alternate methods may be used as long as appropriate studies demonstrate recovery between 75–125% of a known sample spike for half of the value of each specified item.

8.7.3 *Special Reagents*

8.7.3.1 *Water* — The water used for all the dilution, calibration and standards should meet at a minimum the criteria for Type E1.1 in ASTM D5127 in regard to cation analysis.

8.7.3.2 *Indium Internal Standard* — Make up the indium intenal standard solution to a concentration of 20 µg/mL (ppm) from the appropriate concentrated indium standard solution.

8.7.3.3 *Nitric Acid, Ultrapure* — Use nitric acid specified for ultra low metal ion content.

8.7.3.4 *1% Nitric Acid Solution* — Dilute 10 mL of ultrapure nitric acid to 1 L using water meeting the criteria for Type E1.1 in ASTM D5127.

8.7.3.5 *2% Nitric Acid Solution* — Dilute 20 mL of ultrapure nitric acid to 1 L using water meeting the criteria for Type E1.1 in ASTM D5127.

8.7.3.6 *Hydrochloric Acid, Ultrapure* — Use hydrochloric acid specified for ultra low metal ion content.

8.7.3.7 *2% Hydrochloric Acid Solution* — Dilute 20 mL of ultra-pure hydrochloric acid to 1 L using water meeting the criteria for Type E1.1 in ASTM D5127.

8.7.4 *Sample Preparation*

8.7.4.1 *Boron* — In a clean environment, dilute 1.00 g sample with 15.0 g of Type E1.1 water and add 15 µL of the indium internal standard. Run a reagent blank.

8.7.4.2 *Tin* — In a clean environment, place 100 g of sulfuric acid in a quartz crucible. Slowly evaporate to dryness on a hot plate avoiding loss of sample by effervescence or spattering. Cool. Add 2 mL of high purity 12 M hydrochloric acid and 10 mL of water. Cover, and digest on the hot plate for 10 minutes. Cool. Transfer quantitatively to a 50 mL volumetric flask using water for rinsing and dilution to volume. Run a reagent blank.

8.7.5 *All Other Elements* — In a clean environment, place 100 g of sulfuric acid in a quartz crucible. Slowly evaporate on a hot plate avoiding loss of sample by effervescence or spattering until approximately 2 mL of liquid remains. Cool. Add carefully, 1 mL of high purity, 70% nitric acid. While maintaining volume, carefully warm several minutes to dissolve any residue. Cool. Transfer quantitatively to a 50 mL volumetric flask using 2% nitric acid and dilute to volume. Run a reagent blank.

8.7.6 *Analysis* — Using the prepared solutions and blanks, analyze boron by inductively coupled plasma mass spectrometry (ICP/MS). Using the acid sample and reagent blank, analyze group I elements by flame atomic absorption spectroscopy. Analyze all other elements by plasma emission spectroscopy.

NOTE 4: Analysis of dilute sulfuric acid can produce rapid corrosion of nickel cones commonly used in inductively coupled plasma mass spectrometry, platinum cones should be considered as alternative when performing this analysis.

9 Grade 2 Procedures

NOTE 5: Each laboratory is responsible for verifying the validity of the method within its own operation.

9.1 *Non-Metal Impurities* — See Section 8, which contains procedures for the following tests:

Assay

Color (APHA)

Chloride

Nitrate

Phosphate

9.2 *Trace Metals Analysis*

9.2.1 The following method has given satisfactory results in determining metal ion impurities at the values specified for each of the following metals: aluminum (Al), antimony (Sb), arsenic (As), barium (Ba), beryllium (Be), bismuth (Bi), boron (B), calcium (Ca), chromium (Cr), cobalt (Co), copper (Cu), gallium (Ga), germanium (Ge), gold (Au), iron (Fe), lead (Pb), lithium (Li), magnesium (Mg), manganese (Mn), molybdenum (Mo), nickel (Ni), niobium (Nb), potassium (K), silver (Ag), sodium (Na), strontium (Sr), tantalum (Ta), tin (Sn), titanium (Ti), vanadium (V), zinc (Zn), and zirconium (Zr). Alternate methods may be used as long as appropriate studies demonstrate a recovery between 75–125% of a known sample spike for half of the value of each specified element.

9.2.2 Special Reagents

9.2.2.1 *Nitric Acid, Ultrapure* — Use nitric acid specified for low metal ion content.

9.2.2.2 *1% Nitric Acid Solution* — Dilute 10 mL of ultrapure nitric acid to 1 L using water meeting the criteria for Type E1.1 in ASTM D5127.

9.2.2.3 *Water* — The water used for all the dilution, calibration and standards should meet at a minimum the criteria for Type E1.1 in ASTM D5127 in regard to cation analysis.

9.2.2.4 *Indium Internal Standard* — Make up the indium intenal standard solution to a concentration of 20 µg/mL (ppm) from the appropriate concentrated indium standard solution.

9.2.3 *Sample Preparation*

9.2.3.1 *Chromium, Cobalt, Lithium, Manganese, Nickel, Titanium, Vanadium, and Zinc* — In a clean environment, place 1.00 g of sample into a clean quartz dish. Slowly evaporate on a hot plate to dryness avoiding loss of sample by effervescence or spattering. Dissolve the residue with 5 mL of the 1% nitric acid solution by heating on a hot plate at low temperature for several minutes. Cool to room temperature, dilute to 15 mL with 1% nitric acid, add 15 µL of the indium internal standard, mix well. Run a reagent blank.

9.2.3.2 *All Other Elements* — In a clean environment, dilute 1.00 g sample with 15.0 g of Type E1.1 water and add 15 µL of the indium internal standard. Run a reagent blank.

9.2.4 *Analysis*

9.2.4.1 Using the prepared solutions and blanks, analyze sodium, potassium, calcium and iron by graphite furnace atomic absorption (GFAA) and the remaining elements by inductively coupled plasma mass spectrometry (ICP/MS). For calibration, the standards are made up with the 1% nitric acid solution and the indium internal standard such that the final indium concentration is 20 ng/g. For boron and tantalum, the standards for calibration must be matrix matched with equal amounts of sulfuric acid certified to have both elements below 1 µg/mL in the concentrated acid.

NOTE 6: Analysis of dilute sulfuric acid can produce rapid corrosion of nickel cones commonly used in inductively coupled plasma mass spectrometry, platinum cones should be considered as alternative when performing this analysis.

10 Grade 3 Procedures

10.1 This section does not apply to this chemical.

11 Grade 4 Procedures

11.1 This section does not apply to this chemical.

12 Grade 5 Procedures

12.1 This section does not apply to this chemical.

13 VLSI Grade Procedures

13.1 Specific procedures for this grade do not exist. Refer to Sections 8 and 9 for available procedures.

14 Tier A Procedures

14.1 This section does not apply to this chemical.

15 Tier B Procedures

15.1 Standardized test methods are being developed for all parameters at the purity levels indicated. Until standardized test methods are published, test methodology shall be determined by user and producer. The Chemical Reagent Committee considers a test method to be valid only if there is a documented recovery study showing a recovery of 75–125%. Recovery is for a known sample spike at 50% of the specified level.

16 Tier C Procedures

16.1 Standardized test methods are being developed for all parameters at the purity levels indicated. The Process Chemicals Committee considers a test method to be valid if there is a documented recovery study showing a recovery of 75–125%. Recovery is for a known sample spike at 50% of the specified level.

17 Tier D Procedures

17.1 This section does not apply to this chemical.

SEMI C45-0301
SPECIFICATION AND GUIDELINE FOR TETRAETHYLORTHOSILICATE (TEOS)

This specification and this guideline were technically approved by the Global Process Chemicals Committee and are the direct responsibility of the North American Process Chemicals Committee. Current edition approved by the North American Regional Standards Committee on October 17, 1999. Initially available at www.semi.org February 2001; to be published March 2001. This document replaces SEMI C7.13 in its entirety. Originally published in 1991; previously published June 1999.

1 Purpose

1.1 The purpose of this document is to standardize requirements for tetraethylorthosilicate used in the semiconductor industry and testing procedures to support those standards. Test methods have been shown to give statistically valid results. This document also provides guidelines for grades of tetraethylorthosilicate for which a need has been identified. In the case of the guidelines, the test methods may not have been statistically validated yet.

2 Scope

2.1 The scope of this document is all grades of tetraethylorthosilicate used in the semiconductor industry.

2.2 These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 None.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI C1 — Specifications for Reagents

4.2 *ASTM Standards*[1]

ASTM D5127 — Standard Guide for Ultra Pure Water Used in the Electronics and Semiconductor Industry

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 None.

6 Physical Property (for information only)

6.1 Not applicable.

7 Requirements

7.1 The requirements for tetraethylorthosilicate for Grade 1 and Tier A are listed in Table 1.

8 Grade 1 Procedures

NOTE 2: Each laboratory is responsible for verifying the validity of the method within its own operation.

8.1 *Assay* — Analyze the sample by gas chromatography (see SEMI C1, Section 3.1, Guidelines for Assay by Wide Bore Column Gas Chromatography). The parameters cited have given satisfactory results.

8.1.1 *Column* — 30 meter x 530 micron fused silica capillary, coated with 5 micron film of DB-1 or equivalent (100% methyl silicone which has been surface bonded and cross linked).

8.1.2 *Column Temperature* — 60°C isothermal for 1 minute, then programmed to 200°C at 20°C/min.

Injector Temperature:	120°C
Detector Temperature:	260°C
Sample Size:	1 µL splitless
Carrier Gas:	Helium at 3 mL/min
Detector:	Thermal Conductivity
Retention Times (min)	
Water	2.0
Ethanol	2.5
TEOS	7.8

8.2 *Color* — Dilute 1.0 mL of platinum-cobalt stock solution (APHA No. 500) to 100 mL with water. Compare this standard (APHA No. 5) with 100 mL of sample in Nessler tubes. View vertically over a white background. The sample must be no darker than the standard.

8.3 *Water* — The cell is dried with a dry nitrogen gas stream for twenty minutes. Reagents are added and a blank (no sample) is run. Add 5 g of sample to the dry

1 American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, Pennsylvania 19428-2959, USA. Telephone: 610.832.9585, Fax: 610.832.9555. Website: www.astm.org

Coulometric Karl Fischer water analyzer. Results are obtained in ppm by dividing the micrograms of water found in the sample by weight of TEOS in grams.

8.4 *Trace Metals Analysis* —The following method has given satisfactory results in determining trace metal impurities at the specified value for each of the following trace metals: aluminum (Al), arsenic (As), calcium (Ca), chromium (Cr), copper (Cu), iron (Fe), lead (Pb), magnesium (Mg), manganese (Mn), nickel (Ni), potassium (K), sodium (Na), tin (Sn), titanium (Ti), and zinc (Zn). Alternate methods may be used as long as appropriate studies demonstrate recovery between 75–125% of a known sample spike for half of the value of each specified item.

8.4.1 *Special Reagents* — All water used in the *Trace metals Analysis* and *Boron Analysis* should be a deionized water meeting the criteria for Type E1.1 in ASTM D5127.

8.4.1.1 *Mixed Acid* — 1% HF - 2% HNO_3 prepared by dilution of ultra pure acids with appropriate weights of deionized water.

8.4.1.2 *Standards* — Composite standard solutions containing 0, 1, 2, and 4 ppb multi-element standards are prepared by diluting with mixed acid of appropriate weights for ICP-MS. Single-element standards are prepared (Ca, Fe, K, Na) for GFAA.

8.4.2 *Sample Preparation* — In a clean environment, place 100 g of sample in a clean PFA Teflon closed bottle equipped with an inlet and outlet tube and evaporate under a nitrogen purge at approximately 110°C. When dry, close the inlet and the outlet tube and digest the residue at 100°C for 30 minutes with 7 mL of mixed acid solution. Cool and transfer the contents with deionized water. Dilute the transferred contents with deionized water to a final volume of 14 mL.

8.4.3 *Analysis* — Analyze the samples by graphite furnace atomic absorption (GFAA) for sodium, calcium, potassium, and iron. Analyze the sample for all other metallic elements by inductively coupled plasma mass spectrometry (ICP-MS).

8.5 *Boron Analysis* — The following method has given satisfactory results in the determination of trace levels of boron (B). Alternate methods may be used as long as appropriate studies demonstrate recovery between 75–125% of a known sample spike for half of the specified value.

8.5.1 *Standard* — Standards of 0, 2, and 4 ppm boron are prepared by dilution of an aqueous boron stock solution with deionized water meeting the criteria for Type E1.1 in ASTM D5127.

8.5.2 *Sample Preparation* — A 100 g sample of TEOS is extracted with 10 mL of deionized water, that meets the criteria for Type E1.1 in ASTM D5127, by vigorously shaking the solution for minimum of 10 minutes on a mechanical shaker. Allow the layers to separate and remove the aqueous portion to a separate container.

8.5.3 *Analysis* — The 10 mL water extract is analyzed for boron by inductively coupled plasma atomic emission spectroscopy (ICP-AES) at 249.68 nm.

9 Grade 2 Procedures

9.1 This section does not apply to this chemical.

10 Grade 3 Procedures

10.1 This section does not apply to this chemical.

11 Grade 4 Procedures

11.1 This section does not apply to this chemical.

12 Grade 5 Procedures

12.1 This section does not apply to this chemical.

13 VLSI Grade Procedures

13.1 This section does not apply to this chemical.

14 Tier A Procedures

14.1 Standardized test methods are being developed for all parameters at the purity levels indicated. Until standardized test methods are published, test methodology shall be determined by user and producer. The Chemical Reagent Committee considers a test method to be valid only if there is a documented recovery study showing a recovery of 75–125%. Recovery is for a known sample spike at 50% of the specified level.

15 Tier B Procedures

15.1 This section does not apply to this chemical.

16 Tier C Procedures

16.1 This section does not apply to this chemical.

17 Tier D Procedures

17.1 This section does not apply to this chemical.

SEMI C48-0699E
SPECIFICATION AND GUIDELINE FOR 1,1,1-TRICHLOROETHANE*, FURNACE GRADE

This specification and this guideline were technically approved by the Global Process Chemicals Committee and are the direct responsibility of the North American Process Chemicals Committee. Current edition approved by the North American Regional Standards Committee on April 23, 1999. Initially available on SEMI OnLine May 1999; to be published June 1999. This document replaces SEMI C1.26 and C7.15 in their entirety. Originally published in 1988 and 1991 respectively.

E This document was editorially modified in March 2000. Changes were made to the table following Section 8.1.

* CAUTION: Reacts violently with Aluminum and white metals and is not to be used for vapor degreasing. (Contains less than 0.05% inhibitors.)

1 Purpose

1.1 The purpose of this document is to standardize requirements for 1,1,1-trichloroethane, furnace grade used in the semiconductor industry and testing procedures to support those standards. Test methods have been shown to give statistically valid results. This document also provides guidelines for grades of 1,1,1-trichloroethane, furnace grade for which a need has been identified. In the case of the guidelines, the test methods may not have been statistically validated yet.

2 Scope

2.1 The scope of this document is all grades of 1,1,1-trichloroethane, furnace grade used in the semiconductor industry.

3 Limitations

3.1 None.

4 Referenced Documents

SEMI C1 — Specifications for Reagents

5 Terminology

5.1 None.

6 Physical Property (for information only)

Density at 25°C	1.33 g/mL
Boiling Point	73°C

7 Requirements

7.1 The requirements for 1,1,1-trichloroethane, furnace grade for Grade 1 and Tier A are listed in Table 1.

8 Grade 1 Procedures

8.1 *Assay* — Determine the assay using a suitable gas chromatograph. Integrate the areas under all stabalizer and impurity peaks and the 1,1,1-trichloroethane peak. Apply appropriate response factors for the column and detector system to correct the results from area percent to weight percent. The assay shall not be less than 99.9% by weight (see SEMI C1, Section 3.1, Guidelines for Assay by Wide Bore Column Gas Chromatography). The parameters cited have given satisfactory results.

NOTE 1: Calibration standard to be determined between supplier and user.

Column: 30 meter × 530 micron I.D. fused silica capillary, coated with 5 micron film of DB-1 or equivalent (100% methyl silicone which has been surface bonded and cross linked).

Column Temperature: 40°C isothermal for 5 minutes, then programmed to 200°C at 10°C/min.

Injector Temperature:	150°C
Detector Temperature:	250°C
Sample Size:	0.2 µL (splitless)
Carrier Gas:	Helium at 3 mL/min
Detector:	Thermal Conductivity
Approximate Retention Times (min):	
1,1,1-Trichloroethane	10.0

8.2 *Color* — Dilute 2.0 mL of platinum-cobalt stock solution (APHA No. 500) to 100 mL with water. Compare this standard (APHA No. 10) with 100 mL of sample in Nessler tubes. View vertically over a white background. The sample must be no darker than the standard.

8.3 *Acidity* — To 25 mL of water in a glass-stoppered flask, add 10 mL of sample and 0.1 mL of phenolphthalein indicator solution. Add 0.01 N sodium hydroxide until a slight pink color persists after shaking for one-half minute. Add 75 mL (100 g) of the sample, mix well, and titrate with 0.01 N sodium hydroxide until the pink color is reproduced. Not more than 3.0 mL of the sodium hydroxide solution should be required.

8.4 *Residue After Evaporation* — Evaporate 75 mL (100 g) of sample to dryness in a clean environment. Dry at 105°C for 30 minutes, cool in desiccator and weigh to a precision of 0.1 milligram (see SEMI C1, Section 3.3, Determination of Residue After Evaporation).

8.5 *Water* — Add 25 mL of methanol to a dry titration flask and add Karl Fischer (KF) reagent to a visually or electrometrically determined endpoint that persists for 30 seconds. Add 38 mL (50 g) of sample, taking care to protect the sample and contents of the flask from moisture. Stir and titrate with Karl Fischer reagent to:

$$\% \text{ Water } (H_2O) = \frac{\text{mL KF reagent} \times \text{KF factor (g } H_2O\text{/mL)} \times 100}{\text{Weight of sample (g)}}$$

8.6 *Phosphate* — To 75 mL (100 g) of sample, add 10 mL of sodium carbonate reagent solution and evaporate to dryness on a steam bath in a hood. Dissolve the residue in 25 mL of 0.5 N sulfuric acid. Add 1 mL of ammonium molybdate reagent solution. Add 1 mL of p-(methylamino)phenol sulfate reagent solution. Allow to 880 µm in a 1 cm cell should be no greater than that produced when 0.001 mg of phosphate ion (PO_4) is treated as the sample.

SEMI C49-0699
GUIDELINE FOR TRIMETHYLBORATE

This guideline was technically approved by the Global Process Chemicals Committee and is the direct responsibility of the North American Process Chemicals Committee. Current edition approved by the North American Regional Standards Committee on April 23, 1999. Initially available on SEMI OnLine May 1999; to be published June 1999. This document replaces SEMI C7.21 in its entirety. Originally published in 1995.

1 Purpose

1.1 The purpose of this document is to standardize requirements for trimethylborate used in the semiconductor industry and testing procedures to support those standards. Test methods have been shown to give statistically valid results. This document also provides guidelines for grades of trimethylborate for which a need has been identified. In the case of the guidelines, the test methods may not have been statistically validated yet.

2 Scope

2.1 The scope of this document is all grades of trimethylborate used in the semiconductor industry.

3 Limitations

3.1 None.

4 Referenced Documents

4.1 None.

5 Terminology

5.1 None.

6 Physical Property (for information only)

Density at 20°C	0.915 g/mL
Boiling Point	68.7°C

7 Requirements

7.1 The requirements for trimethylborate for Tier A are listed in Table 1.

8 Grade 1 Procedures

8.1 This section does not apply to this chemical.

12.1 This section does not apply to this chemical.

13 VLSI Grade Procedures

13.1 This section does not apply to this chemical.

14 Tier A Procedures

14.1 Standardized test methods are being developed for all parameters at the purity levels indicated. Until standardized test methods are published, test methodology shall be determined by user and producer. The Process Chemicals Committee considers a test method to be valid only if there is a documented recovery study showing a recovery of 75 - 125%. Recovery is for a known sample spike at 50% of the specified level.

15 Tier B Procedures

15.1 This section does not apply to this chemical.

16 Tier C Procedures

16.1 This section does not apply to this chemical.

17 Tier D Procedures

17.1 This section does not apply to this chemical.

SEMI C50-0699
GUIDELINE FOR TRIMETHYLPHOSPHITE

This guideline was technically approved by the Global Process Chemicals Committee and is the direct responsibility of the North American Process Chemicals Committee. Current edition approved by the North American Regional Standards Committee on April 23, 1999. Initially available on SEMI OnLine May 1999; to be published June 1999. This document replaces SEMI C7.22 in its entirety. Originally published in 1995.

1 Purpose

1.1 The purpose of this document is to standardize requirements for trimethylphosphite used in the semiconductor industry and testing procedures to support those standards. Test methods have been shown to give statistically valid results. This document also provides guidelines for grades of trimethylphosphite for which a need has been identified. In the case of the guidelines, the test methods may not have been statistically validated yet.

2 Scope

2.1 The scope of this document is all grades of trimethylphosphite used in the semiconductor industry.

3 Limitations

3.1 None.

4 Referenced Documents

4.1 None.

5 Terminology

5.1 None.

6 Physical Property (for information only)

Density at 20°C	1.05 g/mL
Boiling Point	112°C

7 Requirements

7.1 The requirements for trimethylphosphite for Tier A are listed in Table 1.

8 Grade 1 Procedures

8.1 This section does not apply to this chemical.

9 Grade 2 Procedures

9.1 This section does not apply to this chemical.

10 Grade 3 Procedures

10.1 This section does not apply to this chemical.

11 Grade 4 Procedures

11.1 This section does not apply to this chemical.

12 Grade 5 Procedures

12.1 This section does not apply to this chemical.

13 VLSI Grade Procedures

13.1 This section does not apply to this chemical.

14 Tier A Procedures

14.1 Standardized test methods are being developed for all parameters at the purity levels indicated. Until standardized test methods are published, test methodology shall be determined by user and supplier. The Process Chemicals Committee considers a test method to be valid only if there is a documented recovery study showing a recovery of 75 - 125%. Recovery is for a known sample spike at 50% of the specified level.

15 Tier B Procedures

15.1 This section does not apply to this chemical.

16 Tier C Procedures

16.1 This section does not apply to this chemical.

17 Tier D Procedures

17.1 This section does not apply to this chemical.

SEMI C51-0699
SPECIFICATION FOR XYLENES

This specification was technically approved by the Global Process Chemicals Committee and is the direct responsibility of the North American Process Chemicals Committee. Current edition approved by the North American Regional Standards Committee on April 23, 1999. Initially available on SEMI OnLine May 1999; to be published June 1999. This document replaces SEMI C1.21 in its entirety. Originally published in 1978.

1 Purpose

1.1 The purpose of this document is to standardize requirements for xylenes used in the semiconductor industry and testing procedures to support those standards. Test methods have been shown to give statistically valid results. This document also provides guidelines for grades of xylenes for which a need has been identified. In the case of the guidelines, the test methods may not have been statistically validated yet.

2 Scope

2.1 The scope of this document is all grades of xylenes used in the semiconductor industry.

2.2 This material is a mixture of ortho, meta, and para isomers and ethylbenzene. Xylene (o-, m-, and p- isomers and ethylbenzene) 99.0% min and Ethylbenzene 18% max.

3 Limitations

3.1 None.

4 Referenced Documents

SEMI C1 — Specifications for Reagents

5 Terminology

5.1 None.

6 Physical Property (for information only)

Density at 25°C	0.86 g/mL
Boiling Range	136 - 144°C

7 Requirements

7.1 The requirements for xylenes for Grade 1 are listed in Table 1.

8 Grade 1 Procedures

8.1 *Assay* — Assay the sample by gas chromatography (see SEMI C1, Section 3.1, Guidelines for Assay by Wide Bore Gas Chromatography). The parameters cited have given satisfactory results.

Column: 30 meter × 530 micron I.D. fused silica capillary, coated with 5 micron film of DB-1 or equivalent (100% methyl Silicone which has been surface bonded and cross linked).

Column Temperature: 40°C isothermal for 5 minutes, then programmed to 200°C at 10°C/min.

Injector Temperature:	175°C
Detector Temperature:	250°C
Sample Size:	0.2 µL splitless
Carrier Gas:	Helium at 3 mL/min
Detector:	Thermal Conductivity or Flame Ionization
Approximate Retention Times (min):	
Toulene	14.4
Ethylbenzene	17.0
p-xylene	16.9
m-xylene	17.2
o-xylene	17.8

8.1.1 Measure the areas under all peaks by any convenient means and calulate the concentration of all components in area percent (see SEMI C.1, Section 3.11, Guidelines for Assay by Wide Bore Column Gas Chromatography).

8.2 *Color* — Dilute 2.0 mL of platinum-cobalt stock solution (APHA No. 500) to 100 mL with water. Compare this standard (APHA No. 10) with 100 mL of sample in Nessler tubes. View vertically over a white background. The sample must be no darker than the standard.

8.3 *Acidity* — To 25 mL of water in a glass-stoppered flask, add 10 mL of sample and 0.1 mL of phenolphthalein indicator solution. Add 0.01 N sodium hydroxide until a slight pink color persists after shaking for one-half minute. Add 38 mL (33 g) of the sample, mix well, and titrate with 0.01 N sodium hydroxide until the pink color is reproduced. Not more than 1.0 mL of the sodium hydroxide solution should be required.

8.4 *Residue After Evaporation* — Evaporate 232 mL (200 g) of sample to dryness. Dry at 105°C for 30 minutes, cool in a desiccator, and weigh (see SEMI C1, Section 3.3, Determination of Residue After Evaporation).

8.5 *Water* — Add 25 mL of methanol to a dry titration flask and add Karl Fischer (KF) reagent to a visually or electrometrically determined endpoint that persists for 30 seconds. Add 23 mL (20 g) of sample, taking care to protect the sample and contents of the flask from moisture. Stir vigorously and titrate with Karl Fischer reagent to the same endpoint.

$$\% \text{ Water } (H_2O) = \frac{\text{mL KF reagent } \times \text{ KF factor (g } H_2O/\text{mL) } \times 100}{\text{Weight of sample (g)}}$$

8.6 *Chloride* — To a 100 mL separatory funnel, add 12 mL (10 g) of sample and 40 mL of water. Shake well for 30 seconds and allow the two layers to separate. Discard the sample (upper) layer. To a 20 mL portion of the water layer add 1 mL of nitric acid and 1 mL of silver nitrate reagent solution. Any turbidity produced should be no greater than that of a standard containing 0.015 mg of chloride ion (Cl) in an equal volume of solution and the amounts of reagents used.

8.7 *Phosphate* — To 12 mL (10 g) of sample, add 10 mL of sodium carbonate reagent solution and evaporate to dryness on a steam bath in a hood. Dissolve the residue in 25 mL of 0.5 N sulfuric acid. Add 1 mL of ammonium molybdate reagent solution and 1 mL of p-(methylamino)phenol sulfate reagent solution. Allow to stand at room temperature for 2 hours. Any blue color should be no greater than that produced when 0.01 mg of phosphate ion (PO_4) is treated as the sample.

8.8 *Arsenic and Antimony (as As)* — Evaporate 116 mL (100 g) of sample in a 250 mL beaker to a small volume in a hood. Add 50 mL of water and again evaporate to a small volume. Repeat the evaporation three times with water additions. Do not allow to go to dryness. Add 5 mL of nitric acid and 5 mL of sulfuric acid and evaporate to dense fumes of sulfur trioxide. Cool, cautiously add 10 mL of water, and again evaporate to dense fumes of sulfur trioxide. Cool, and cautiously wash into a generator flask with water to make a volume of 35 mL. Proceed as described in the General Method for Arsenic (and Antimony) under SEMI C1, Section 3.4.5, starting with the sentence which begins, "Swirl the flask..." Any red color in the silver diethyldithiocarbamate solution of the sample should be no greater than that of the standard containing 0.001 mg of arsenic (As).

8.9 *Trace Element Contents* — By a suitable emission spectrographic procedure, determine for each of the specified trace elements that its content is not greater than the stated specification limit (see SEMI C1, Section 3.5, Guidelines for Determination of Trace Elements by Emission Spectrography).

SEMI C53-0302
SPECIFICATIONS FOR DIMETHYL SULFOXIDE (DMSO) [GRADES 1 AND 2]

These specifications were technically approved by the Global Process Chemicals Committee and are the direct responsibility of the European Process Chemicals Committee. Current edition approved by the European Regional Standards Committee on December 20, 2001. Initially available at www.semi.org January 2002; to be published March 2002. Originally published November 2001.

1 Purpose

1.1 The purpose of this document is to standardize requirements for dimethyl sulfoxide used in the semiconductor industry and testing procedures to support those standards. Test methods have been shown to give statistically valid results.

2 Scope

2.1 The scope of this document is all grades of DMSO used in the semiconductor industry.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety health practices and determine the applicability or regulatory limitations prior to use.

3 Limitations

3.1 None.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI C1 — Specifications for Reagents

5 Terminology

5.1 None.

6 Physical Property (for information only)

Density (d 20/4)	1.10 g/mL

7 Requirements

7.1 The requirements for dimethyl sulfoxide for grades 1 and 2 are listed in Table 1.

8 Grade 1 and Grade 2 Procedures

8.1 *Assay* — Analyze the sample by gas chromatography (see SEMI C1, Section 3.1, Guidelines for Assay by Wide Bore Column Gas Chromatography). The parameters cited have given satisfactory results.

8.1.1 *Column* — 50 meter × 320 micron I.D. fused silica capillary, coated with 5 micron film of OV-1 or equivalent (100% methyl silicone which has been surface bonded and cross linked).

Column Temperature:	135°C isothermal
Injector Temperature:	240°C
Detector Temperature:	280°C
Sample Size:	1 µl
Carrier Gas:	Helium at 1.2 mL/min.
Detector:	Flame ionization
Approximate Retention Times (min):	
Dimethylsulfide	3.8
Dimethylsulfoxide	10.9
Dimethylsulfone	14.1

8.2 *Color* — Using a colorimeter, compare sample in a specific glass tube with flat bottom, graduated at 113 and 250 mm, with a standardized color reference disk CAA (Scale 2.5 to 30 APHA units).

8.3 *Water* — Use a Karl Fischer (KF) coulometer, consisting of a titration beaker, an electrode generator and an electrode indicator with double platinum wire; having as reagents Hydranal Coulomat A solution at the anode and Hydranal Coulomat C solution at the cathode. Add 500 µl of sample, taking care to protect the sample from moisture. Read directly the water content of sample in µg of water.

8.4 *Acidity* — Use a potentiograph with a compound glass electrode and a titration vat with nitrogen inlet. To 100 mL of sample add 5 mL of water, 5 mL of methanol and 2 drops of titan yellow under nitrogen-stream. The titration is performed with N/100 tetrabutylammonium hydroxide (TBAH) in isopropanol. The equivalence point is at about −400 mV. The density (see SEMI C1, Section 3.8) of the Dimethyl sulfoxide sample to be titrated must be determined to express the result in mgKOH/g.

8.5 *Residue after Evaporation* — The residue after evaporation is defined as the relative amount of residue remaining after evaporation of a sample of DMSO followed by heating of the residue: Heat a clean 200 mL beaker at 105°C in an oven for 30 min., cool for 30 min. in a dessicator charged with calcium chloride and weigh. Place 100 g of DMSO into the 200 mL tared beaker. Evaporate the liquid gently, so that boiling does not occur, in a hood protected from any possibility of contamination. When all the sample has evaporated, dry the residue in an oven at 105°C for 30 minutes and cool the beaker for 30 min in a dessicator charged with calcium chloride and reweigh.

8.5.1 Calculate the residue as parts per million (ppm).

8.6 *Trace Metal Determination* — The following method has given satisfactory results in determining trace metal impurities at the value specified for each of the following trace metals : aluminium (Al), antimony (Sb), arsenic (As), boron (B), calcium (Ca), chromium (Cr), copper (Cu), gold (Au), iron (Fe), lead (Pb), magnesium (Mg), manganese (Mn), nickel (Ni), potassium (K), sodium (Na), tin (Sn), titanium (Ti) and zinc (Zn). Alternate methods may be used as long as the method has been validated according to SEMI C1 Section 3.14.

8.7 *Special Reagents*

8.7.1 *Water* — The water used for all the dilution, calibration, and standards should meet suggested guidelines for pure water for Semiconductor processing.

8.7.2 *Sample Preparation* — In a clean environment, dilute 25 mL of sample by adding 25 mL of water. Prepare reagent blanks.

8.7.3 *Analysis* — Using the prepared sample and reagent blanks, analyse the elements by inductively coupled plasma (ICP). The density (see SEMI C1, Section 3.8) of the DMSO sample must be determined to express the result in ppb.

8.7.4 *Notes*

NOTE 1: Each laboratory is responsible for verifying the validity of the method within its own operation.

Table 1 Impurity Limit and Other Requirements for Dimethyl Sulfoxide

Semiconductor Equipment and Materials International

SEMI T1-95
SPECIFICATION FOR BACK SURFACE BAR CODE MARKING OF SILICON WAFERS

NOTICE: The user's attention is called to the possibility that compliance with this specification may require use of an invention covered by patent rights. By publication of this specification, SEMI takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this specification. Users of this specification are expressly advised that determination of any such patent rights, and the risk of the infringement of such rights, are entirely their own responsibility.

1 Scope

1.1 This specification defines the content and location of a back surface bar code marking for silicon wafers. The code is variable in length from 7 to 18 characters which are user-definable. A character position is held constant for the checksum character, but all else is variable. No other information is encrypted into the code. This allows the performance requirements of related bar code reading equipment to be simplified. In addition, provision is made for an optional alphanumeric marking of the size specified in SEMI M12 to enable operator identification of wafers. This alphanumeric code is not intended to be machine readable.

NOTE 1: The example as described in Table 1 and Figure 1 pertains to a hard mark applied by the silicon wafer manufacturer.

1.2 This specification applies to flatted or notched silicon wafers of nominal diameter 125 mm and larger, as specified in SEMI M1.

1.3 The bar code can be read bi-directionally without impairing its decodability.

2 Applicable Documents

2.1 *SEMI Standards*

SEMI M1 — Specifications for Polished Monocrystalline Silicon Wafers

SEMI M12 — Specification for Serial Alphanumeric Marking of the Front Surface of Wafers

3 Terminology

3.1 *background — of a bar code symbol* — the uniform lighter or more reflective region, including quiet zones, that provides contrast for the darker bars.

3.2 *bar — in a bar code symbol* — the darker or less reflective element of the symbol.

3.3 *bar code density* — the number of characters, exclusive of quiet zones, that can be represented in a linear unit of measure.

NOTE: Bar code density can be expressed in characters per inch (cpi) or characters per millimeter (cpmm).

3.4 *bar code symbol* — an array of rectangular bars and spaces that are arranged in a predetermined pattern following specific rules to represent elements of data that are referred to as characters.

NOTE: The symbol is comprised of message characters and start/stop characters, check characters, and quiet zones as required by a particular symbology to form a complete scannable entity.

3.5 *bar code character* — a single group of bars and spaces which represent an individual number, letter, punctuation mark, or other symbol.

3.6 *bar height — of a bar code symbol* — the bar dimension perpendicular to the bar width.

3.7 *bar width — of a bar code symbol* — the perpendicular distance across a bar between the points on opposite edges that have a reflectance that is midway between the background and bar reflectance.

3.8 *bi-directional bar code symbol* — a bar code symbol capable of being read successfully, either by scanning from right to left or from left to right.

3.9 *character — of a bar code* — a single group of bars and spaces that together represent an individual numeral, letter, punctuation mark, or other symbol.

3.10 *character set* — the complete range of characters available for encoding within a particular bar code symbology.

3.11 *check character — of a bar code symbol* — a character included within the symbol whose value is used for the purpose of mathematical verification of the accuracy of the read.

3.12 *continuous code* — a bar code symbol in which all spaces within the symbol are parts of characters so that there are no inter-character gaps.

3.13 *element — of a bar code symbol* — a single bar or space.

3.14 *module — of a bar code symbol* — narrowest element, bar, or space.

3.15 *nominal width — of a bar code element* — the average width of each size element.

3.16 *quiet zone — of a bar code symbol* — a clear background area that precedes the start character and follows the stop character of the symbol.

3.17 *self-checking bar code symbol* — a bar code symbol that uses a checking algorithm that can be applied against each character such that substitution errors can only occur if two or more "printing" defects appear within a single character.

3.18 *self-clocking bar code symbol* — a bar code symbol in which the number of modules, bars, and spaces is the same in each character.

3.19 *space — in a bar code symbol* — the more reflective element of the symbol, usually formed by the background between bars.

3.20 *start/stop character — in a bar code symbol* — special characters that provide initial timing references and direction-of-read information to the decoding logic.

3.21 *start/stop character pattern* — a special bar code character that provides the scanner with start and stop reading instructions as well as scanning direction. The start character is at the left end of a BC-412 symbol (position #2). The stop character is at the right end of the symbol (position #11).

3.22 *symbol* — a combination of characters, including start/stop characters, quiet zones, data characters, and check characters, required by a particular symbology, which form a complete scannable entity.

4 Method of Marking

4.1 The dot matrix laser method shall be used to write characters. The minimum bar matrix shall be 1 dot horizontal and 11 dots/mm vertical as shown in Table 1 and Figure 1. The minimum matrix for alphanumeric characters shall be as specified in SEMI M12. In either case, more dots may be used, up to and including a solid line.

5 BC-412 Code[1]

5.1 *Characteristics* — BC-412 is a presence-absence bar code symbology which uses an alphanumeric character set as outlined in Table 2. The name BC-412 is derived from the method used to encode data characters. Each data character is comprised of four single-width bars incremented within 12 modules. The code is a continuous code.

5.2 *Character Set* — The character set available for marking wafers consists of the ten digits (0−9) and all capital letters in the English alphabet except O as listed in Table 3. In addition, there is a start character and a stop character.

5.2.1 *Character Construction and Value* — The module sequence and value for use in calculating the check character are listed for each character in Table 3.

5.3 *Symbol Content* — All character count and content in the wafer marking symbol are user-definable and vary in number from 7 to 18. The checksum character position is fixed.

6 Optional Alphanumeric Code

6.1 The optional alphanumeric symbol is variable and user definable, and similar to existing SEMI standards M12 and M13 with respect to font style.

6.2 The characters may be oriented with the bottom or top of each character toward the primary fiducial user definable.

6.3 The characters in the optional alphanumeric symbol are those in position #3 through position # (n+2) of the BC-412 symbol (see Table 4).

7 Code Field Locations

7.1 The code field locations for flatted and notched wafers are specified in Figures 3 and 4, respectively. Values of the dimensions for both cases are given in Table 5.

7.2 The dimensions given in Table 5 are those found on the finished wafer, regardless of where in the process the wafer is marked.

7.3 These dimensions are derived with the assumption that both the bar code and the optional alphanumeric markings are placed on the wafer without realignment of the wafer.

7.4 The code field locations are defined by the limits of the bar code elements and the optional alphanumeric characters. Character dimensions are from centerline to centerline of the extreme features of the character.

1 IBM Corporation, 2000 Purchase Street, Purchase, NY 10577, Director of Commercial Relations

8 Definition of the Error-Detecting Method

8.1 Define the following symbols:

$CD =$ Check character

$i =$ Position of a data character within a string from left to right, $i \geq 1$

$CV(i) =$ Character value of i (Table 4)

$$F_o = Mod_{35}\left(\quad CV(i)_{i=odd} \right)$$

$$F_e = Mod_{35}\left(\quad CV(i)_{i=even} \right)$$

$$F = Mod_{35}\left(F_o + 2F_e\right)$$

8.2 Compute the check character:

8.2.1 Assign the value "0" to the check character (position #4, second character in string).

8.2.2 Calculate F_o and F_e.

8.2.3 Calculate F.

8.2.4 Calculate CD as $Mod_{35}(17 \times F)$.

8.3 *Verification*

8.3.1 Recalculate F_e and F_o with the value of CD found in Section 8.2.4 to the second character in the string (position #4).

8.3.2 Calculate F.

8.3.3 If F = 0, the check character is correct.

8.4 As an example, calculate the check character for A_Q45670 as follows:

8.4.1 Write the code as A0Q45670.

8.4.2 Calculate F_o, F_e, and F:

$$F_o = Mod_{35}(A(i) + Q(i) + 5(i) + 7(i)) =$$

$$F_o = Mod_{35}(7 + 18 + 33 + 21) = Mod_{35}(79) = 9$$

$$F_o = Mod_{35}(0 + 11 + 19 + 0) = Mod_{35}(30) = 30$$

$$F = Mod_{35}(9 + 60) = Mod_{35}(69) = 34$$

8.4.3 Calculate the value for CD:

$$CD = Mod_{35}(17 \times 34) = Mod_{35}(578) = 18$$

8.4.4 This corresponds to the character, Q, so the symbol is now AQQ45670.

8.4.5 Verify that the check character in AQQ45670 is correct as follows:

$$F_o = Mod_{35}(A(i) + Q(i) + 5(i) + 7(i))$$
$$= Mod_{35}(7 + 18 + 33 + 21) = Mod_{35}(79) = 9$$
$$F_e = Mod_{35}(Q(i) + 4(i) + 6(i) + 0(i))$$
$$= Mod_{35}(18 + 11 + 19 + 0) = Mod_{35}(48) = 13$$
$$F = Mod_{35}(F_o + 2F_e)$$
$$= Mod_{35}(9 + 26) = Mod_{35}(35) = 0$$

F	0.700 mm ref.	same	0.700 mm ref.	same
G[3]	5.400 mm ± 0.500 mm	13.320 mm ± 0.500 mm	5.400 mm ± 0.500 mm	13.320 mm ± 0.500 mm
H[3]	10.800 mm ± 0.050 mm	26.640 mm ± 0.050 mm	10.800 mm ± 0.050 mm	26.640 mm ± 0.050 mm
J	2.000 mm ± 0.025 mm	same	2.000 mm ± 0.025 mm	same
L[3]	13.200 mm ± 0.050 mm	29.040 mm ± 0.050 mm	13.200 mm ± 0.050 mm	29.040 mm ± 0.050 mm
M[2]	1.260 mm min.	same	1.260 mm min.	same

[1] This dimension is the distance between the centerline of the bottom dot in the bar code and the edge of the finished wafer.
[2] This dimension is the distance between the centerline of the first module of the start character (or the last element of the stop character) and the outer edge of the Quiet Zone.
[3] n = 7 and n = 18 values represent the smallest to the largest extremes of the bar code symbology to be used.

The formulas for calculating all other values in between are as follows:

$$\text{Dimension (B)} \text{ (Using SEMI M12 Sizing)} = \frac{((n\text{-}1)\ \text{Character Spacing}) + (\text{Character Width})}{2}$$

$$= \left| \frac{((n\text{-}1) \times 1.420) + 0.812}{2} \pm 0.500 \right| \text{mm} = ((0.710n - 0.304) \pm 0.500)\ \text{mm}$$

$$\text{Dimension (C)} = (((n - 1) \times 1.420) + 0.812 \pm 0.050)\ \text{mm} = ((1.420n - 0.608) \pm 0.050)\ \text{mm}$$

$$\text{Dimension (G)} = \left| \frac{((12n) \times 0.120) + (6 \times 0.120)}{2} \pm 0.500 \right| \text{mm} = ((0.720n - 0.360) \pm 0.500)\ \text{mm}$$

$$\text{Dimension (H)} = (((12n) \times 0.120) + (6 \times 0.120) \pm 0.050)\ \text{mm} = ((1.440n - 0.720) \pm 0.050)\ \text{mm}$$

$$\text{Dimension (L)} = (((12n) \times 0.120) + (6 \times 0.120) \pm (20 \times 0.120) \pm 0.050\ \text{mm} = ((1.440n - 3.120) \pm 0.050)\ \text{mm}$$

Tolerance for module spacing is non - cumulative (see Table 1).

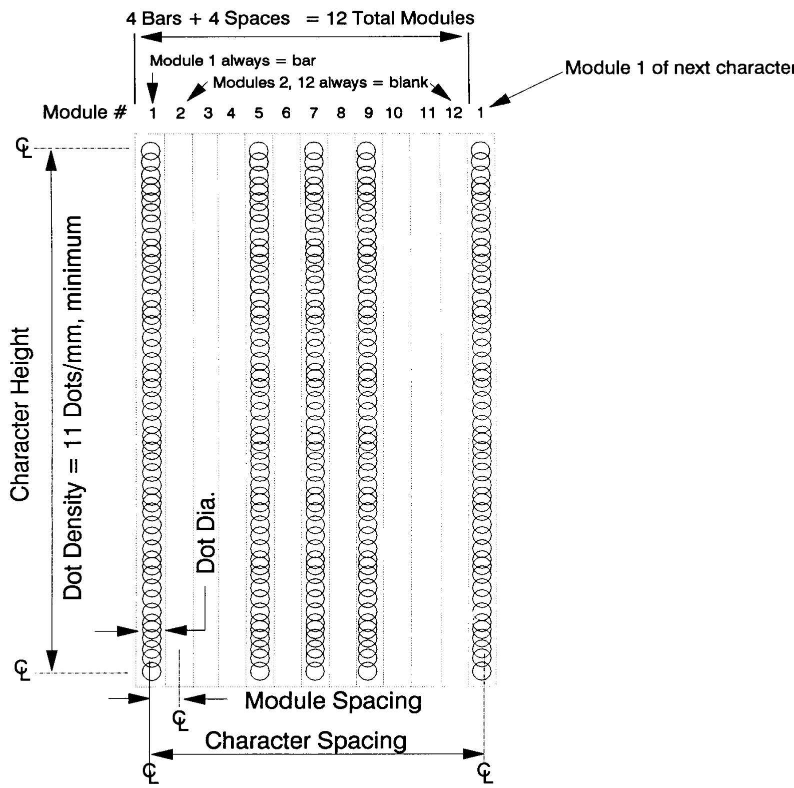

Figure 1
BC-412 Data Character Construction

NOTE 2: Each bar code character contains four bars and four spaces. A space is one or more contiguous blanks. Module 1 is always a bar; the other three bars are distributed among modules 3−11; modules 2 and 12 are always spaces. One or more blanks which comprise a space must occur between bars.

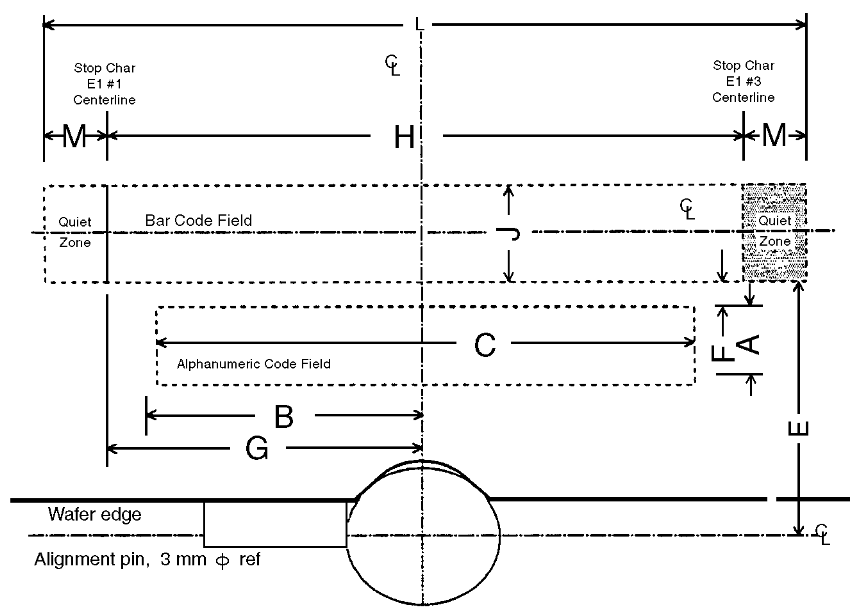

Figure 4
Code Field Locations for Notched Wafers

APPLICATION NOTE 1

NOTE: This application note is not an official part of SEMI T1 and is not intended to modify or supercede the official standard. Rather, this note is provided primarily as a source of information to aid in the application of the standard. As such, it is considered reference material only. The standard should be referred to in all cases.

A1-1 Center Reference Dimensions for Bar Code and Optional Alphanumeric Marks

A1-1.1 The following information is provided as a reference for equipment which employs center referencing to locate the bar code or optional alphanumeric marks. Dimensions for flatted wafers are given in Table A1-1 and dimensions for notched wafers are given in Table A1-2.

A1-2 Referenced Documents

SEMI T2-0298[E]

SPECIFICATION FOR MARKING OF WAFERS WITH A TWO-DIMENSIONAL MATRIX CODE SYMBOL

This specification was technically approved by the Global Traceability Committee and is the direct responsibility of the North American Traceability Committee. Current edition approved by the North American Traceability Committee on April 30, 1999. Initially available on SEMI OnLine April 1999; to be published June 1999. Originally published in 1993.

This entire document was revised in February 1998.

[E] This document was modified in April 1999 to reflect the creation of SEMI AUX1 as the source for vendor identification codes. Changes were made to numerous sections. This document was also modified in April 2000 to clarify patent issues. Changes were made to the notice at the end of this document.

1 Purpose

1.1 This specification is intended to provide a marking symbology that can be used to mark silicon wafers with minimum intrusion into the fixed quality area of the wafer.

2 Scope

2.1 This specification defines the geometric and spatial relationships and content (including the error checking and correcting code) of a two-dimensional (2-D), machine-readable, binary matrix code symbol for front surface marking of wafers of silicon which comply with SEMI M1, SEMI M2, or SEMI M11, and other materials with diameters of 125 to 200 mm. This specification allows for consistency of all wafer marking performed by wafer manufacturers. It may be used in conjunction with, or as an alternative to, the alphanumeric marking codes specified in SEMI M12 and SEMI M13 or a front surface bar code like that specified in SEMI T1.

2.2 Although this specification does not specify the marking techniques that may be employed when complying with its requirements, it is assumed that the symbol will be obtained by laser scribing individual dots.

2.3 The 2-D matrix code is applicable to a broad range of wafer products, including epitaxial wafers, SOI wafers, and unpatterned or patterned polished wafers. The format and algorithms of this code are based on the Data Matrix two-dimensional symbology specified in AIM International Symbology Specification - Data Matrix.

SEMI M12 — Specification for Serial Alphanumeric Marking of the Front Surface of Wafers

SEMI M13 — Specification for Alphanumeric Marking of Silicon Wafers

SEMI T1 — Specification for Back Surface Bar Code Marking of Silicon Wafers

3.2 *AIM International Technical Specification*[1]

AIM International Symbology Specification - Data Matrix

3.3 *ANSI Standard*[2]

ANSI X3.4 — American Standard Code for Information Interchange (ASCII)

NOTE 1: This standard is equivalent to ISO 646, Information Processing - ISO 7-bit Coded Character Set for Information Processing.

4 Terminology

4.1 *binary values* — a dot in the wafer surface indicates the binary value 1. The absence of a dot, or a smooth surface surrounding a cell center point, indicates the binary value 0.

4.2 *border column* — the outermost column of a data matrix code symbol.

4.3 *border row* — the outermost row of a data matrix code symbol.

4.4 *cell, of a data matrix code symbol* — the area within which a dot may be placed to indicate a binary value.

[1] *AIM International Inc., 11860 Sunrise Valley Drive, Suite 100, Reston, VA 20191, tel 703.391.7621, fax 703.391.7624*

[2] *American National Standards Institute, 11 West 42nd Street, New York, NY 10036, tel 212.642.4900, fax 212.398.0023*

4.5 *cell center point, of an array* — the point at which the centerline of a row intersects the centerline of a column.

4.6 *cell spacing, of an array* — the (equal) vertical or horizontal distance between the cell center points of contiguous cells.

4.7 *center line, of a row or column* — the line positioned parallel to, and spaced equally between, the boundary lines of the row or column.

4.8 *central area, of a cell* — the area enclosed by a circle centered at the cell center point; used by code readers to sense the binary value of the cell.

4.9 *data matrix code symbol* — a two-dimensional array of square cells arranged in contiguous rows and columns.

4.10 *dot* — a localized region with a reflectance which differs from that of the surrounding surface.

NOTE 2: To assure reading efficiency, a minimum contrast of 30% is required between the reflectance value of a dot and the surrounding wafer surface. Various densitometers can provide such measurements nondestructively.

4.11 *dot misalignment, within a cell* — the distance between the physical center point of a dot and the cell center point.

4.12 *reference point, of a data matrix code symbol* — the physical center point of a corner cell common to a border row and border column, used to identify the physical location of the symbol on the object being marked with the symbol.

NOTE 3: The reference point is at a fixed location on the object. Different cells may be chosen as the reference point, depending on the desired orientation of the symbol on the object and the size variability of the symbol. The particular cell to be used as the reference point must be specified for each application.

5 Ordering Information

5.1 Purchase orders for wafers furnished to this specification shall include the following items:

5.1.1 *Message Characters*

5.1.1.1 Quantity (10 to *nn*, where *nn* is 11–31 and depends on the character set to be encoded (see Table 1).

5.1.1.2 Content of Message Characters 11 and up, if present.

5.1.2 Cell Spacing (125 or 150 µm).

6 Requirements

6.1 *Shape and Size of the Matrix Code Symbol*

6.1.1 Each square matrix code symbol shall be composed of an equal even number (from 16 to 20) of rows and columns of equally spaced square cells. Cell spacing shall be either 125 or 150 µm. (See Table 2, and Figures 1 and 2.)

6.1.2 *Dot Size* — The nominal shape of the dot produced in the matrix may be circular or square. Its diameter or edge length (after polishing) shall be 100 ± 10 µm.

6.2 *Border Rows and Columns (see Figure 3)*

6.2.1 One border row and one border column shall contain a dot in each cell. These are identified as the primary border row and the primary border column. These are used by the code reader to determine the reference point and orientation of the matrix.

6.2.2 The opposing (secondary) border row and column shall contain dots in alternating cells.

6.2.3 The reference point of the symbol shall be the physical centerpoint of the cell common to the primary border row and the secondary border column.

6.2.4 The maximum dot misalignment within a cell is 20 µm. This ensures that a minimum size dot covers a cell central area of radius 25 µm. (See Figure 4.)

Table 1 Matrix Code Symbol Dimensions

Square Arrays for Use on 125 to 200 mm Wafers	*C_1, R_1 (µm)**			*C_2, R_2 (µm)**		
# of cells in row or column	16	18	20	16	18	20
125 µm spacing	1875	2125	2375	2000	2250	2500
150 µm	2250	2550	2850	2400	2700	3000

*See Figure 1 for pictorial representation of Dimensions C_1, C_2, R_1, and R_2.

Table 2 Message Character Count in Square Arrays for Use on 125 to 200 mm Wafers

# of Cells in a Row or Column		*16*	*18*	*20*
Maximum # of Message Characters	8-bit	10	16	20
	Mostly upper-case	16	25	31

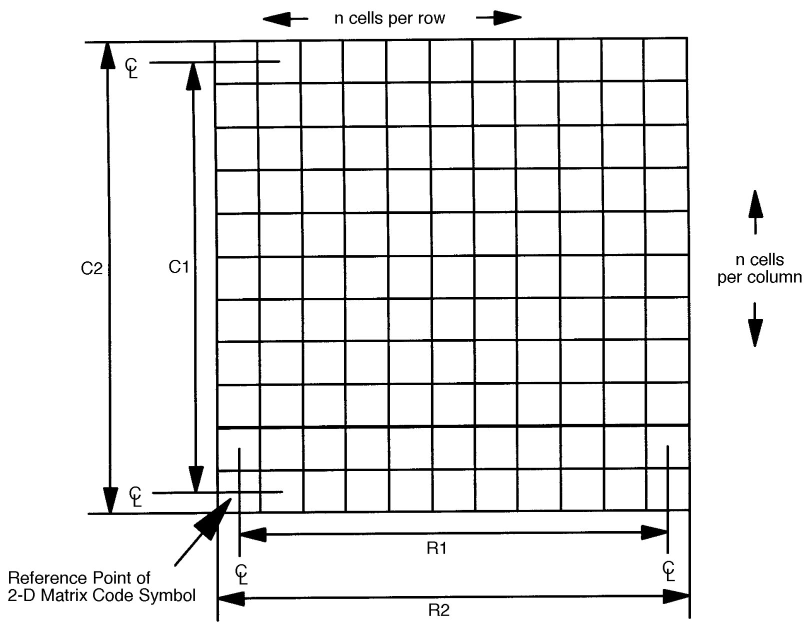

Figure 1
Data Matrix Field Dimensions

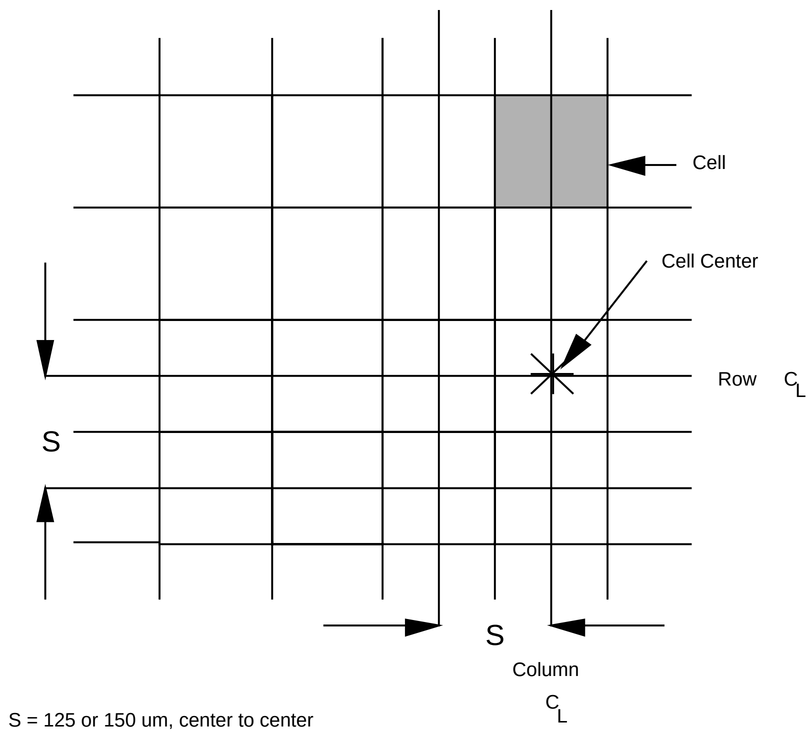

Figure 2
Data Matrix Cell Spacing

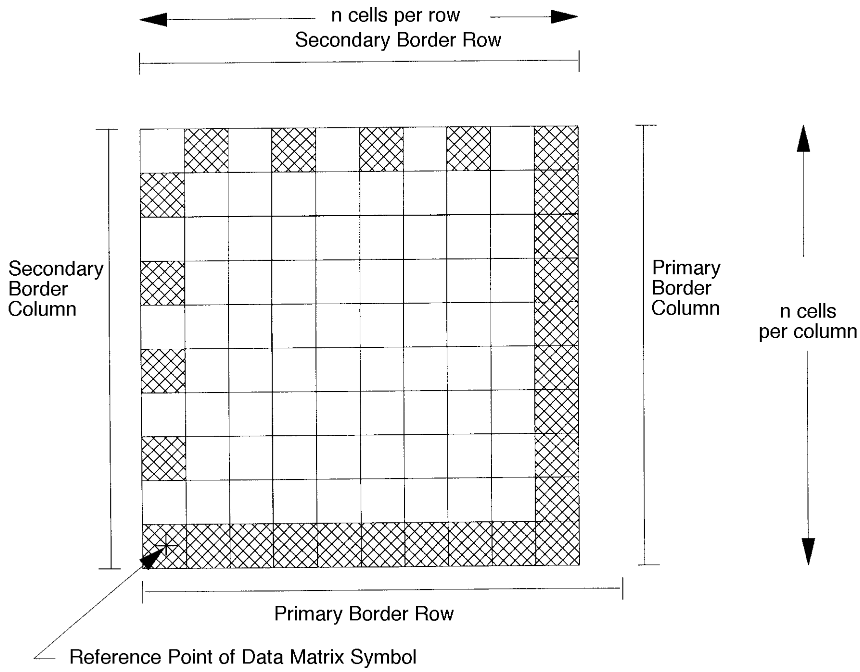

Figure 3
Border Rows and Columns: ECC200

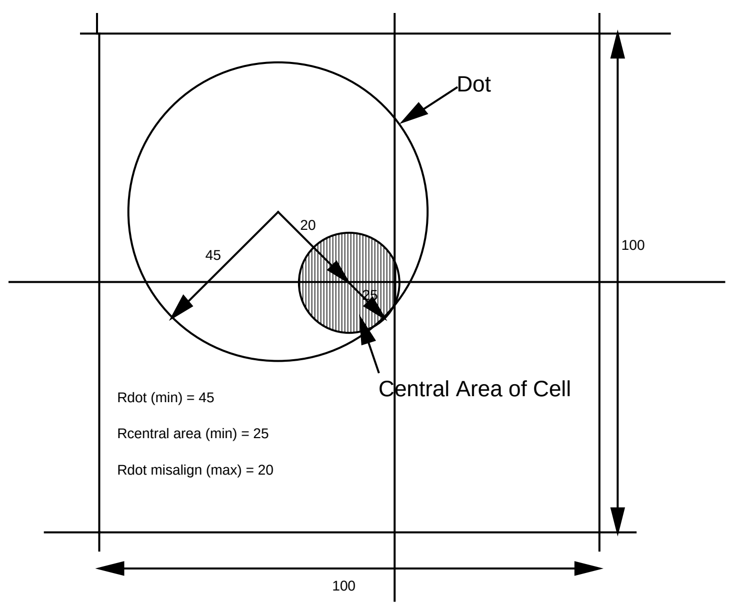

Figure 4
Minimum Size Dot with Maximum Dot Misalignments (all Dimensions in µm)

6.3 *Content of the Matrix Code Symbol*

6.3.1 Each square matrix code symbol shall contain between 10 and 23 message characters encoded in accordance with AIM ISS Data Matrix, including the characters associated with error checking and correcting (ECC200), as also defined in AIM ISS Data Matrix.

6.3.2 The message characters may include any of those designated as "mostly uppercase" in Table 5 and Annex J of AIM ISS - Data Matrix. The first 10 message characters shall contain two elements:

a vendor-assigned 8-character wafer identification code, followed by

a 2-character vendor identification code as defined in SEMI AUX1.

6.3.2.1 The remaining message characters, if any, shall contain information as agreed between the vendor and user.

6.3.3 The total number of message characters available depends on the row/column count and on the encoded character set. (See Table 2.)

6.4 *Location of the Matrix Code Symbol*

6.4.1 With the wafer positioned front surface up and with the primary fiducial toward the operator, the reference point of the matrix code symbol shall be located as specified in Table 3.

6.4.2 The square matrix code symbol used on 125 to 200 mm diameter wafers shall be oriented with the border columns parallel with the primary fiducial bisector and the border rows perpendicular to the primary fiducial bisector. The secondary border column shall be toward the primary fiducial bisector, and the primary border row shall be toward the edge of the wafer.

6.4.3 The nominal position of the reference point of the matrix code symbol is 1 mm to the right of the closest alphanumeric code field. A 3º skew toward the alphanumeric field, which is the maximum skew allowed by SEMI M12 and SEMI M13, does not cause the matrix code symbol to impinge on the alphanumeric code fields, even if the symbol is placed only 15.5 mm from the primary fiducial bi-sector. Consequently, this matrix code symbol position permits the simultaneous use of front surface alphanumeric marking as specified in SEMI M12 or M13, on 125 to 200 mm wafers with either flatted or notched primary fiducials.

6.4.4 Because the matrix code symbol is located in the same place with respect to the primary fiducial bisector on all wafer diameters from 125 to 200 mm, the use of both marking and reading equipment is simplified.

6.4.5 The distance from the edge of the data matrix code symbol to the diameter perpendicular to the primary fiducial bisector varies according to the actual size of the wafer and the placement of the symbol within its tolerance range. Minimum distances from the edge of the code symbol to the wafer center-line are given in Table 4 for both 16 × 16, 125 µm and 20 × 20, 150 µm matrix code symbols.

Table 3 Location of Matrix Code Symbol — Wafer Polished Side Up, Primary Fiducial toward the Operator

Type of Array	*Wafer Fiducial*	*Reference Point Cell*	*Location of Symbol Reference Point*
Square (used on 125, 150, and 200 mm wafers)	Flat	Common cell of primary border row and secondary border column	16.0 ± 0.5 mm to the right of the fiducial bisection, and 2.5 ± 0.5 mm above the edge of the flat
	Notch		160 ± 0.5 mm to the right of the fiducial bisector, and 5.3 ± 0.5 mm above the notch pin center

Table 4 Minimum Distances from Edge of Matrix Code Symbol to the Wafer Centerline

APPENDIX 1
SIMULTANEOUS MARKING WITH SQUARE DATA MATRIX AND ALPHANUMERIC CODES

NOTE: The material in this appendix is an official part of SEMI T2 and was approved by full letter ballot procedures on 7/15/97.

A1-1 The relative positions of alphanumeric and data matrix markings are shown in Figure A1-1. This figure also shows the relationship between the data matrix code symbol and the edge of the polished area of the front surface of the wafer. Wafer peripheries in the figure are the edges of the polished area of wafers with maximum intrusion of the edge contour, minimum diameter, and maximum flat diameter (minimum flat length), or distance between the notch pin centerline and the wafer edge, as specified in SEMI M1. For all wafer diameters, SEMI M1 allows the edge contour to extend inward from the edge up to 508 µm (Dimension B in Figure 4 of SEMI M1). The distance between the notch pin centerline and the wafer periphery may vary from 0.30 to 0.80 mm as indicated in Figure 6 of SEMI M1. Other dimensions and tolerances are specified in the appropriate polished wafer specification in SEMI M1.

A1-2 Alphanumeric code field locations are shown for all cases except the SEMI M13 code field for flatted wafers, which lies entirely to the left of the primary fiducial bisector. Note that alphanumeric code field locations are not specified for 125 mm diameter notched wafers in either SEMI M12 or SEMI M13.

A1-3 The nominal position of the reference point of the data matrix code symbol is marked by a +; this position is 1 mm to the right of the closest alphanumeric code field. Because of the tolerances on the position of the reference point, the largest data matrix code symbol (20 × 20, 150 µm cell spacing) may lie anywhere within the dotted square. The effect of a 3º skew toward the alphanumeric field is also shown. Although the skew does not affect readability of the data matrix code symbol, too great a skew may cause the data matrix symbol code to impinge on occupied areas of the wafer surface. The 3º skew, which is the maximum allowed by SEMI M12 and SEMI M13, does not cause the data matrix code symbol to impinge on the alphanumeric code fields.

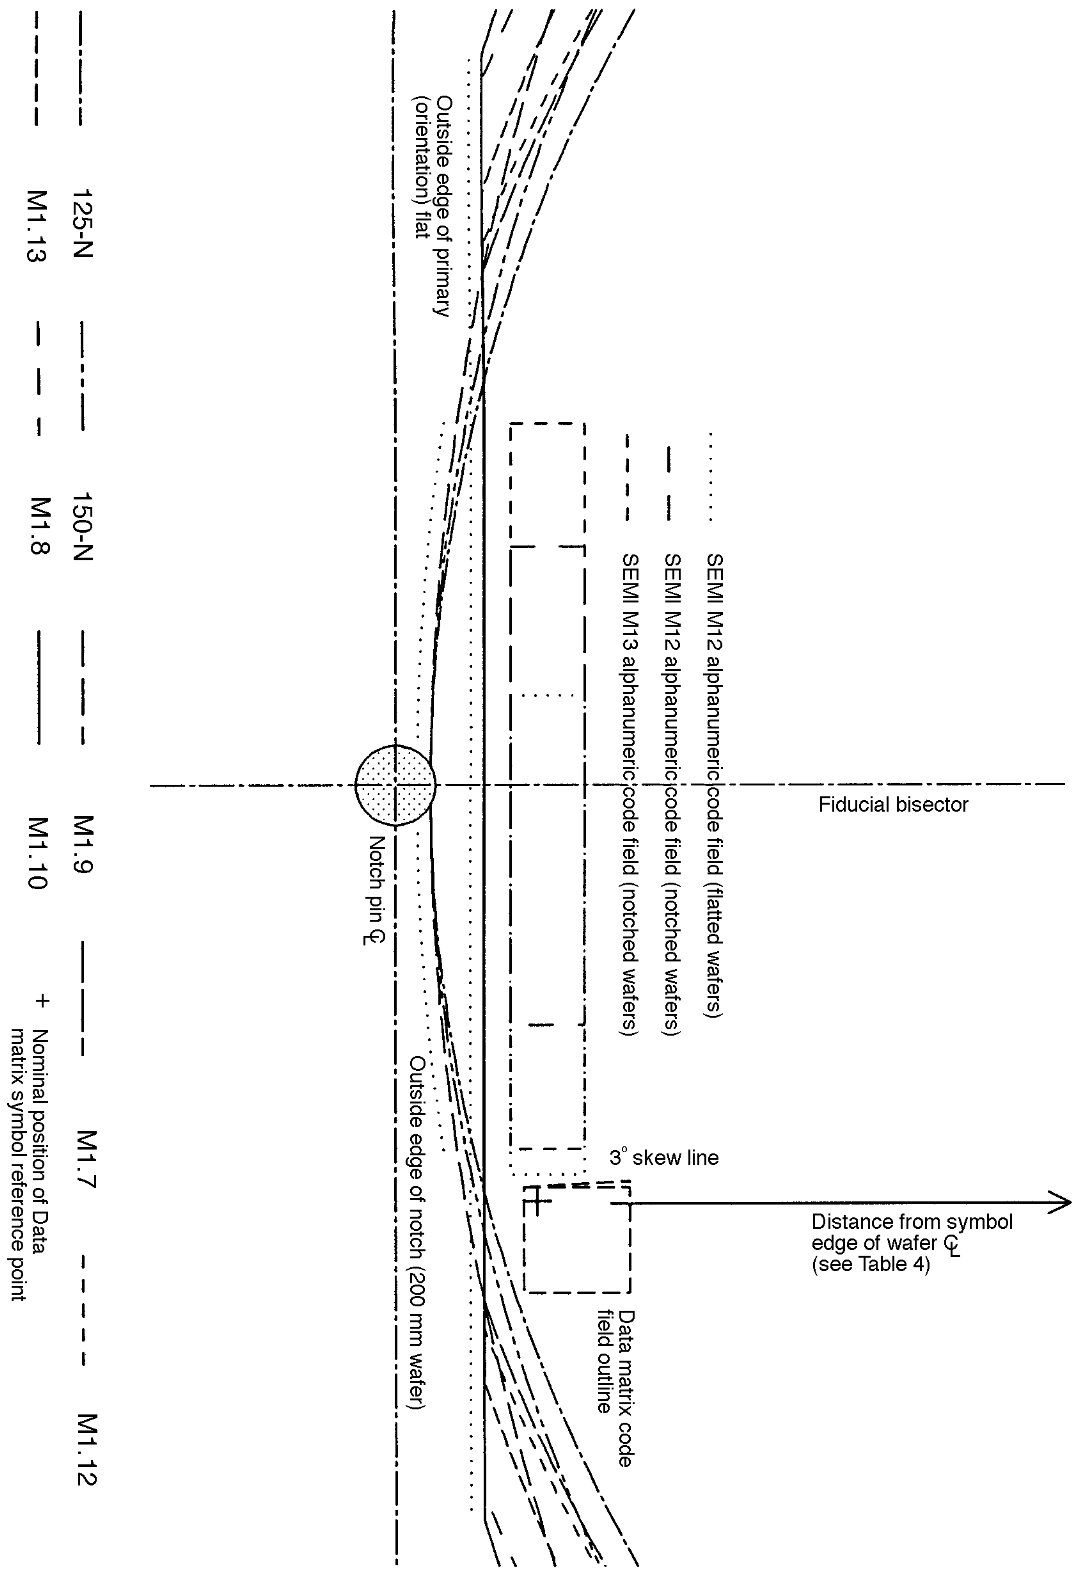

Figure A1-1
Relationship between the Maximum Size Matrix Code Symbol, Alphanumeric Fields, and the Edges of the Polished Front Surface of Minimum Size Wafers

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require the use of copyrighted material or of an invention covered by patent rights. RVSI Acuity CiMatrix has filed a statement with SEMI asserting that the patented or copyrighted item can be used by the public for the purpose of implementing this standard without specific license and without payment of royalty or other charge. Attention is also drawn to the possibility that some elements of this standard may be subject to patented technology or copyrighted items other than those identified above. Semiconductor Equipment and Materials International (SEMI) shall not be held responsible for identifying any or all such patented technology or copyrighted items. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights and the risk of infringement of such rights are entirely their own responsibility.

SEMI T3-0302
SPECIFICATION FOR WAFER BOX LABELS

This specification was technically approved by the Global Traceability Committee and is the direct responsibility of the North American Traceability Committee. Current edition approved by the North American Regional Standards Committee on November 27, 2001. Initially available at www.semi.org February 2002; to be published March 2002.

NOTE: This document was entirely rewritten for publication in 2002.

1 Purpose

1.1 This specification provides a common format, content, size, and location for printed, machine-readable labels on wafer boxes to facilitate communication of data essential for advanced traceability and electronic data exchange systems. These labels differ from those used in common commercial practice in that they provide less detailed information about parametric properties of the wafer. Such information is now readily stored in advanced traceability systems.

1.2 This specification covers labels that contain two bar code symbols and their associated human-readable interpretation.

1.3 This specification also covers a two-dimensional Data Matrix code symbol that can accommodate substantially more information than can the bar code symbols. This symbol is included to provide for a smooth transition from existing traceability and labeling procedures to the comprehensive, unified system envisioned for the future in which common reading equipment can be used throughout the plant. If the Data Matrix symbol is used without the bar code symbols, provision is made for an associated human readable interpretation.

1.4 Labels provided in accordance with this specification satisfy the special requirements of 300 mm Wafer Shipping Systems, detailed in SEMI M45, for both front opening shipping box (FOSB) labels and bag labels.

2 Scope

2.1 This specification covers size, message content and symbology requirements of labels for wafer boxes used for storage and transport of silicon wafers 100 mm in diameter and larger.

2.2 For wafer boxes used with 100 to 200 mm diameter wafers, this specification provides for two similar labels in order that the contents of the wafer box can be identified when the wafer box is stored in either of two positions: with the side of the wafer box parallel with the front of the storage shelf or with the end of the wafer box parallel with the front of the storage shelf. Because wafer boxes are routinely stacked for storage, placement of box labels on the top or bottom of the box is not recommended.

2.3 For FOSBs used with 300 mm wafers, this specification provides for two identical labels, one to be placed on the FOSB and the other to be placed on the outer bag. These requirements are consistent with the requirements of SEMI M45. SEMI M31 specifies FOSB dimensions.

2.4 The message content and locations of the symbols used on the labels covered by this specification are designed to fit in a space consistent with size of the available flat area on wafer boxes investigated. If a larger flat area is available on the wafer boxes to be used, the label size may be increased and additional message content included.

2.5 This specification includes descriptions of the characteristics of the code formats to be employed.

2.6 The labels covered by this specification may be applied on the box itself, and on the box wrap portion of the wafer package, but not on the transport package (outer shipping carton) used for commercial transportation of wafer packages.

NOTE 1: Specifications for transaction labels, which are intended for use on the outer shipping carton, are given in ANSI/EIA 556-B.

2.6.1 The format of the barcode is based on Code 39, as specified in ISO/IEC 16388.

2.6.2 The format of the Data Matrix Code is specified in ISO/IEC 16022.

2.7 Wafer box labels are intended to be applied in a cleanroom environment concurrent with the completion of production of the wafers. Although it is recognized that the materials of construction and the adhesives used to apply the label must be selected with this use in mind, their specification is beyond the scope of this document.

2.8 The dimensions in this specification are applicable to labels printed with printers that have nominal resolution of 203 dots per inch (dpi). Printers with higher resolution may be used, but many of the dimensions may differ from those in this specification and the code fields may or may not fit within the specified label size and format. In such cases, the user of this specification must ensure that the label is of a size that fits the box to be employed.

2.9 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety health practices and determine the applicability or regulatory limitations prior to use.

4 Terminology

4.1 Definitions of terms relating to wafer boxes (see Figure 1) are as follows:

4.1.1 *bar end, of a wafer box base* — the end of the box base that is next to the first pocket of the cassette inside the base or the first pocket of the base itself.

4.1.2 *base, of a wafer box* — the open-top container into which wafers are placed, either in cassettes or into integrally molded pockets.

4.1.3 *box wrap* — the wrapping or bagging applied over the wafer box to comprise the product package.

NOTE 2: The box wrap is usually sealed under clean room conditions.

4.1.4 *cover, of a wafer shipping box* — the portion of the box which closes the top of the base.

4.1.5 *wafer box* — a sealable container consisting of a base and a cover, used for storing or transporting wafers. Compare with *transport package* in ANSI/EIA-556-B.

4.1.6 *wafer box label* — the label on the wafer box identifying the product and its manufacturer.

4.1.7 *wafer package* — the combination of a wafer box and box wrap.

4.1.8 *wall end, of a wafer shipping box* — the end of the shipping box that is opposite the bar end.

4.2 Terms relating to FOSBs are defined in SEMI M31.

4.3 Terms relating to bar code characteristics are defined in SEMI T1. Definitions for additional terms relating to the product package, product package label, and bar code format and characteristics can be found in ANSI/EIA-556-B, Appendix A.

4.4 Terms relating to the data matrix code symbol characteristics are defined in SEMI T2 and ISO/IEC 16022.

4.5 Definitions of terms relating to code content are as follows:

4.5.1 *customer information field* — a 35-character field containing the customer product ID and, if desired, other customer assigned information.

4.5.2 *customer product ID* — a unique combination of alphanumeric characters assigned by a customer or purchaser to identify a product, sometimes called customer part number.

4.5.3 *data field* — a specific portion or area of a label designated to contain a human readable interpretation, a bar code symbol, or a two-dimensional matrix code symbol.

4.5.4 *data identifier* — a specified character or character string that defines the category or intended use of data that follows.

4.5.5 *encrypted data* — data entered by the vendor, usually to facilitate traceability, that may or may not be shared with the customer.

4.5.6 *human readable interpretation (hri)* — the interpretation of all or a portion of a bar or matrix code symbols presented in a type font which can be read by persons.

4.5.7 *message character* — a character that contains data, encoded into a bar or matrix code symbol.

NOTE 3: Data identifiers and concatenation characters are considered to be message characters, but start/stop characters are not.

4.5.8 *message length* — the number of message characters contained in a single encoded message.

4.5.9 *traceability number, of a wafer box label* — a string of 35 message characters comprising a lot number, vendor code (including manufacturing location, if desired), and date of labeling together with the appropriate data identifier and concatenation characters.

5 Ordering Information

5.1 Purchase orders for the wafers furnished with wafer box labels in conformance with this specification shall include the following:

5.1.1 Statement that the wafer box label conforms to SEMI Specification T3.

5.1.2 Content of message characters for customer information field.

5.1.3 Label type (see Section 7.1) or, if additional space is available on the box, dimensions of labels and placement of fields thereon.

5.2 In addition, the following optional items may be specified:

5.2.1 If a two-dimensional matrix code symbol is included on the label:

5.2.1.1 Inclusion or exclusion of wafer identification information.

5.2.1.2 User-specified data, if required, and requirement, if any, for sharing of code for encrypted data.

5.2.2 Label locations on the wafer box, if different from the recommended locations.

6 Content and Characteristics of Data Fields

6.1 *Bar Code Symbols*

6.1.1 The label shall contain two data fields for bar code symbols, when such symbols are specified. Each bar code symbol shall contain 35 message characters in addition to the start/stop characters.

6.1.2 A non-printed message header is normally encoded when encoding multiple, concatenated data fields. However, this header is not encoded in the bar code fields to conserve space. The absence of this message header requires appropriate software in bar code reading systems, to separate the data fields.

6.1.3 The upper bar code data field, the customer information field (see Table 1 and Figure 2a), shall contain the customer product ID preceded by a “P,” the data identifier for this item as specified in ANSI MH10.8.2.

6.1.3.1 Optionally, if the customer product ID occupies less than 34 characters, the customer identification field may also contain one or more of the subfields listed below, up to the limit of 35 characters total. Each optional subfield shall be preceded by the concatenator symbol “+ ” and the data identifier(s) below, in accordance with ANSI MH 10.8.2.

6.1.3.2 Field Identifier for *customer part number revision*: 2P

6.1.3.3 Field Identifier for *customer specification number*: 20P

6.1.3.4 Field Identifier for *customer specification revision*: 21P

6.1.3.5 Field Identifier for *customer drawing number*: 12P

6.1.3.6 Field Identifier for *customer drawing revision*: 22P

6.1.4 The lower bar code data field (see Table 2 and Figure 2b) shall contain the 35-message character traceability number. This field is divided into four subfields, each separated from the adjacent field by the concatenation symbol "+ ." The first subfield contains the lot number of 16 characters, preceded by the data identifier "1T." The second subfield contains the 2-character SEMI vendor identification code, preceded by the data identifier "1V. " The third subfield contains the labeling date (YYMMDD), preceded by the data identifier "D. " The fourth subfield contains the quantity, preceded by the data identifier "Q. " The quantity indicated on the label shall be the number of wafers in the wafer box to which the label is affixed; the unit of measure is understood as each (EA). The message characters in this symbol are distributed as shown in Table 2.

Table 1 Content of Bar Code Symbol in Upper Bar Code Data Field (Customer Information Field)

Number of characters	*Symbol Content*	*Notes*
	Required Subfield	
First 1	Data Identifier	"P"
message dependent	Customer Product ID (e.g. part number)	(Customer-specified)
	Optional Subfields	
3	Concatenator + Data Indentifier	"+ 2P"
message-dependent	Customer Part Number Revision	(Customer-specified)
4	Concatenator + Data Indentifier	"+ 20P"
message-dependent	Customer Specification Number	(Customer-specified)
4	Concatenator + Data Indentifier	"+ 21P"
message-dependent	Customer Specification Number Revision	(Customer-specified)
4	Concatenator + Data Indentifier	"+ 12P"
message-dependent	Customer Drawing Number	(Customer-specified)
4	Concatenator + Data Indentifier	"+ 22P"
message-dependent	Customer Drawing Revision	(Customer-specified)

NOTE 1: The total number of characters in the field shall not exceed 35; any character location not filled with data shall contain a dash.

Table 2 Content of Bar Code Symbol in Lower Bar Code Data Field (Traceability Number)

Character Location	*Symbol Content (All required fields)*	*Notes*
1–2	Data Identifier	"1T"
3–18	Lot Number	(Supplier assigned)
19–21	Concatenation Symbol and Data Identifier	"+ 1V"
22–23	Vendor Identification Code	(SEMI) (See Note 1)
24–25	Concatenation Symbol and Data Identifier	"+ D"
26–31	Labeling Date	(YYMMDD) (See Related Information 1)
32–33	Concatenation Symbol and Data	"+ Q"
34–35	Quantity (unit, EA, implied)	(numeric)

NOTE 1: The SEMI vendor identification code may contain information on manufacturing location. AUX1 contains multiple codes indicating manufacturing location for some, but not all, wafer suppliers. If desired, suppliers whose codes do not now include manufacturing location identification can request additional codes for each location from SEMI, following the procedure in AUX1.

6.1.5 All bar code symbols shall use the Code 39 bar code as specified in ISO/IEC 16388, unless an optional bar code is selected (see Section 6.1.9). Code 39 is a variable length, discrete, self-checking, bi-directional bar code. Each character is composed of nine elements: Five bars and four spaces. Three of the nine elements are wide and six elements are narrow.

6.1.6 *Character Set* — The Code 39 character set consists of 43 characters: 0-9, A-Z,+ ,-,.,$,/,%, and space. In addition, an asterisk (*) is used only for both the start and stop characters; it cannot be used as a message character. No other characters shall be encoded in the bar code symbols of labels covered by this specification. In the absence of a character at any assigned location, a dash (-) shall be used.

6.1.7 *Print Quality* — The Code 39 print quality shall be B/03/630 or better in accordance with ANSI X3.182. To assure reading efficiency, the minimum reflectance of the quiet zones shall be 60%, the minimum reflectance of spaces shall be 51%, and the maximum reflectance of bars shall be 10%.

6.1.8 *Symbol Dimensions* — Bar code symbol dimensions shall be as listed in Table 3.

6.1.9 *Other Bar Code Symbology* — Code 128 may be used in lieu of Code 39. Users must verify that this code fits within the available label space.

6.2 *Human-Readable Interpretation Symbols*

6.2.1 Each bar code symbol data field on the label shall have an associated human-readable data field either immediately above or immediately below it. The symbol in each of the human-readable data fields shall contain all the message characters contained in the associated bar code data field. Start and stop characters shall not be included, but the data field identifiers and concatenation symbols shall be included.

6.2.2 The nominal height of the human-readable characters shall be 2.0 mm (0.08 in.).

6.2.3 There shall be a clear space of 0.5 mm (0.02 in.) above and below each human-readable symbol.

6.3 *Data Matrix Code Symbol*

6.3.1 The label may contain up to two identical square two-dimensional matrix code symbols each with up to 682 message characters when six-bit characters are encoded using the EDIFACT encodation scheme described in Annexe J3 of ISO/IEC 16022 (see also Table 11 in ISO/IEC 16022).

6.3.2 The first six characters shall contain the message header, in accordance with EIA 706; this header identifies a message that contains data identifiers that are in accordance with ANSI MH10.8.2. The header content is not printed.

6.3.3 The next 71 characters in the matrix code symbol shall contain the information included in the two bar code symbols on the label, together with additional concatenation symbols, as summarized in Table 4. In the absence of a character at any assigned location, a dash (-) shall be used. This information shall also be included if the bar codes are not printed.

Table 3 Nominal Dimensions of Bar Code 39 Symbols

Symbol	*Dimension*	*Metric (SI) Value*	*U.S. Customary Value*
-	number of message characters	35	35
X	width of narrow bar	0.125 mm	0.00493 in.
N	ratio of wide to narrow bar width	2.0	2.0
I	nominal intercharacter gap	0.1251 mm	0.00493 in.
H	bar height (See Note 1.)	9.0 mm	0.35 in.
L'	bar code symbol length (excl. quiet zones)	60.06 mm	2.365 in.
-	bar code density (excl. quiet zones)	0.583 cpmm	14.80 cpi
Q	width of quiet zone (See Note 1.)	6.35 mm	0.25 in.
L	total length of bar code symbol	72.76 mm	2.865 in.

NOTE 1: The metric (SI) and U.S. Customary values of this dimension are not exact equivalents; the dimension has been rounded to obtain rational values in both systems.

6.3.4 For boxes to be used for wafers between 100 and 200 mm in diameter, the content of the remainder of the data matrix code symbol is optional, as agreed between the customer and supplier. However, it is recommended that the remaining message characters in the Data Matrix code symbol include the following 500-character wafer identification information. For labels to be used on 300 mm FOSBs, the wafer identification information is required, in accordance with SEMI M45.

6.3.4.1 These next 500 characters identify the slot number and individual wafer identification of each wafer in the box, with a string of 25 twenty-character fields. Each of these fields contains:

a. The concatenation character (“+ ”) and Data Identifier for the slot ID (“31T”) and a two-digit number of the slot, and

b. the concatenation character (“+ ”) and Data Identifier for the ID of the wafer in that slot (“32T”) and the ten-character wafer ID including the two-character vendor identification code. The wafer ID number is comprised of

i) the first ten characters of the marking codes specified in SEMI M12, SEMI M13, or SEMI T2, or

ii) all ten characters of the marking code specified in SEMI T7.

NOTE 4: The content of the marking code specified in SEMI T1 is not specified. This standard may not be suitable for use with wafers marked with the marking code specified in SEMI T1.

6.3.4.2 The cassette/box slot sequence assumes slot 01 at the bar end and slot 25 at the other end of the box. Data matrix code symbols on labels on boxes or cassettes with less than 25 slots shall have one field for each slot.

Table 4 Message Character Content of Matrix Code Symbols

Character		*Symbol Content*	*Notes*
Location	*Count*		
		General Information	
1–6	6	Message Header	<d237>
7	1	Data Identifier	“P”
8–41	34	Customer Information (see Table 2)	(Customer-assigned)
42–44	3	Concatenation Symbol and Data Identifier	“+ 1T”
45–60	16	Lot Number	(Supplier-assigned)
61–63	3	Concatenation Symbol and Data Identifier	“+ 1V”
64–65	2	Vendor Identification Code	(SEMI)
66–67	2	Concatenation Symbol and Data Identifier	“+ D”
68–73	6	Labeling Date	(YYMMDD) (See Related Information 1)
74–75	2	Concatenation Symbol and Data Identifier	“+ Q”
76–7	2	Quantity (unit, EA, implied)	(numeric)
	77	Subtotal for general information	
		Wafer Information (Optional, see 6.3.4 and 6.3.4.1)	
78–81	4	Concatenation Symbol and Data Identifier	“+ 31T”(See Note 8)
82–83	2	Slot Number	(numeric, 01-25)
84–87	4	Concatenation Symbol and Data Identifier	“+ 32T”
88–97	10	Wafer Identification Number	
	20	Subtotal for one wafer	
98–577	480	Subtotal for next 24 wafers	
	500	Subtotal for wafer information	
	577	Total for General + Wafer Information	
		Encrypted or Customer-specific Data (Optional)	
577–682	up to 105	As needed	Otherwise unused character locations (See Note 9)

NOTE 1: If wafer identification data are not available or are not desired for a particular application, additional supplier-specified and/or customer-specified data fields may be included in these character locations as agreed upon between customer and supplier. Begin each supplier-specified field with a data identifier from the series 31T to 34T and each customer-specified field with a data identifier from the series 20T to 24T. Separate adjacent fields with the concatenation symbol (+).

NOTE 2: These unused character locations are available for encrypted or unencrypted supplier-specified information or for customer-specified information. These characters do not appear in the bar code symbol, but only in the Data Matrix Code Symbol. Begin the field with the concatenation symbol (“+ ”) followed by an appropriate data identifier as defined in Note 1; in the unlikely event that more than one field is included, begin each field with an appropriate identifier and separate adjacent fields with the concatenation symbol. If the field is not filled completely with characters it is not necessary to pad with dashes; the encoding software will pad it automatically.

6.3.4.3 All slots shall be represented in the Data Matrix code. The first identification number shall be that of the wafer in slot 01 at the bar end; the second, that of the wafer in slot 02; and so on. An empty slot shall be designated by dashes. For shipping boxes containing 100 to 200 mm diameter wafers, slot 01 is at the bar end of the box. For 300 mm FOSBs, slot 1 is specified by SEMI M31 to be at the bottom of the FOSB.

6.3.5 Any character locations not otherwise used may contain information whose content shall be agreed to between supplier and customer. These characters may consist of customer-specified data or supplier-specified data (which may be encrypted) or both.

6.3.6 The data matrix code shall be a square field, constructed in accordance with ISO/IEC 16022, using error correction code ECC200.

6.3.7 *Dot Size* — The nominal shape of the dot produced in the matrix may be circular or square, depending on the printing technique. It is recommended that each " cell" of the data matrix symbol be composed of at least four dots (a cell with two dots per edge). When printed at 203 dpi, the dot diameter or edge length is 0.125 mm (0.00985 in.).

6.3.8 *Symbol Dimensions* — Each matrix code symbol shall be composed of 80 rows and 80 columns of cells spaced equally with cell spacing *S* (see Figure 3). The nominal outside dimensions of the matrix (C2 and R2 in Figure 4), printed with 4 dots per cell at 203 dpi is 20 mm.

6.3.9 *Border Rows and Columns (see Figure 4)*

6.3.9.1 The leftmost border row and the bottom border column shall contain dots in each cell. These are identified as the primary border row and the primary border column.

6.3.9.2 The opposing (secondary) border row and column shall contain dots in every other cell.

6.3.9.3 These border rows and columns are used by the code reader to determine the origin, size, and orientation of the matrix.

6.3.9.4 The origin of the matrix code symbol shall be the physical center point of the cell common to the primary border row and the primary border column.

NOTE 5: This origin location differs from that used in SEMI T2.

6.3.10 *Message Characters* — The matrix code symbol contains 682 8-bit message characters.

Table 5 Nominal Dimensions of Wafer Box Labels and All Data Fields

Dimension	*Metric (SI) Value*	*U.S. Customary Value*
A (see Note 11)	25 mm	1 in.
B (see Note 11)	0.75 mm	0.04 in.
C (see Note 11)	1.0 mm	0.04 in.
D (see Note 11)	0.50 mm	0.02 in.
E (see Note 11)	2.0 mm	0.08 in.
F (see Note 11)	24.24 mm	0.95 in.
H (see Note 11)	9.0 mm	0.35 in.
J	2.0 mm	0.08 in.
K (see Note 12)	20.0 mm	0.788 in.
L´	60.06 mm	2.365 in.
L	72.76 mm	2.865 in.
P	119.0 mm	4.69 in.
Q	6.35 mm	0.25 in.
S (see Note 11)	30.0 mm	1.19 in.
T (see Note 11)	24.0 mm	0.95 in.
U (see Note 11)	2.5 mm	0.106 in.

NOTE 1: The Metric (SI) and U.S. Customary values of this dimension are not exact equivalents; the dimension has been rounded to obtain rational values in both systems.
NOTE 2: Printed at 4 dots/cell and 203 dpi.

6.3.10.1 The initial six characters are a non-printed message header. The next 570 characters are restricted to the Code 39 Character Set (see 6.1.6) using the six-bit EDIFACT encodation scheme described in Annexe J3 of ISO/IEC 16022. The remaining 105 message characters may be any character in the EDIFACT Encodation Character Set, including unprinted ones. These 105 characters are available for encrypted or unencrypted information, as negotiated between supplier and customer.

6.3.11 *Print Quality* — To assure reading efficiency, a minimum contrast of 30% is required between the reflectance value of a dot and the surrounding label surface. Various densitometers can provide such measurements nondestructively.

7 Label Types, Label Dimensions, and Placement of Data Fields on Labels

7.1 *Label Types (see Figure 5 for examples)*

7.1.1 *Type 1* — Company Field + Data Matrix Field with hri fields

7.1.2 *Type 2* — Company Field + Bar Code Field with hri fields

7.1.3 *Type 3* — Company Field + Data Matrix Field + Bar Code Field with hri fields. Two of this type of label are required for use on 300 mm FOSBs.

NOTE 6: The space reserved on the FOSB rear surface accepts labels as large as 120 mm by 120 mm. This permits the use of labels wider than is specified in this standard. Such labels may contain additional information as arranged by agreement between customer and supplier.

7.1.4 *Type 4* — Company Field + Data Matrix Field1 + Bar Code Field with hri fields + Data Matrix Field2 with hri fields

7.1.5 *Type 5* — Company Field + two Data Matrix Fields, both with hri fields

7.2 Each label shall contain an area containing Company Information and one or more areas containing bar codes, data matrix codes, and related human-readable information.

7.2.1 The Company Information area may contain supplier-related information in human-readable alpha-numeric format and other information as agreed to between customer and supplier.

7.2.2 The other fields that contain bar code, human-readable, and two-dimensional matrix code data fields, may be arranged as indicated in the examples shown in Figure 5.

7.2.3 The human-readable (hri) data fields can be placed either above or below their associated bar code data fields. The examples in Figure 5 show the configuration with the hri fields above the bar code data fields.

7.3 Approximate overall dimensions of the five label types shown in Figure 5 are tabulated in Table 6.

7.4 Dimensions of individual fields, label height, and label length for a type 4 label are given in Table 5 and Figure 6. Label types 4 and 5 may use perforated label material so that the sections may be separated after printing.

Table 6 Overall Dimensions of Box Labels

Label Type	*Length*			*Width*		
	Symbol	*mm*	*in.*	*Symbol*	*mm*	*in.*
1	F+ S	54.2	2.1	A	25.0	1.0
2	F+ L	97.0	3.8	A	25.0	1.0
3	P=F+ T+ L	119.0	4.7	A	25.0	1.0
4	P+ S	149.0	5.9	A	25.0	1.0
5	F+ 2S	84.2	3.3	A	25.0	1.0

NOTE 1: For meaning of the symbols, see Table 5.

8 Label Locations on Wafer Box

8.1 For boxes containing wafers from 100 to 200 mm in diameter, the following recommendations apply.

8.1.1 It is recommended that label type 4 or label type 5 be used for these boxes. These label types may be printed on perforated label material so that the sections may be separated after printing.

8.1.2 The recommended location for the larger label is the center (both vertically and horizontally) of the side of the cover of the wafer box facing the operator with the bar end to the left and the wall end to the right (see Figure 7). Alternatively, this label may be placed in the center of the same side of the base of the wafer box.

8.1.3 The recommended location for the smaller label is the center (both vertically and horizontally) of the wall end of the base of the wafer box (see Figure 7). Alternatively, this label may be placed at the center of the wall end of the cover of the wafer box.

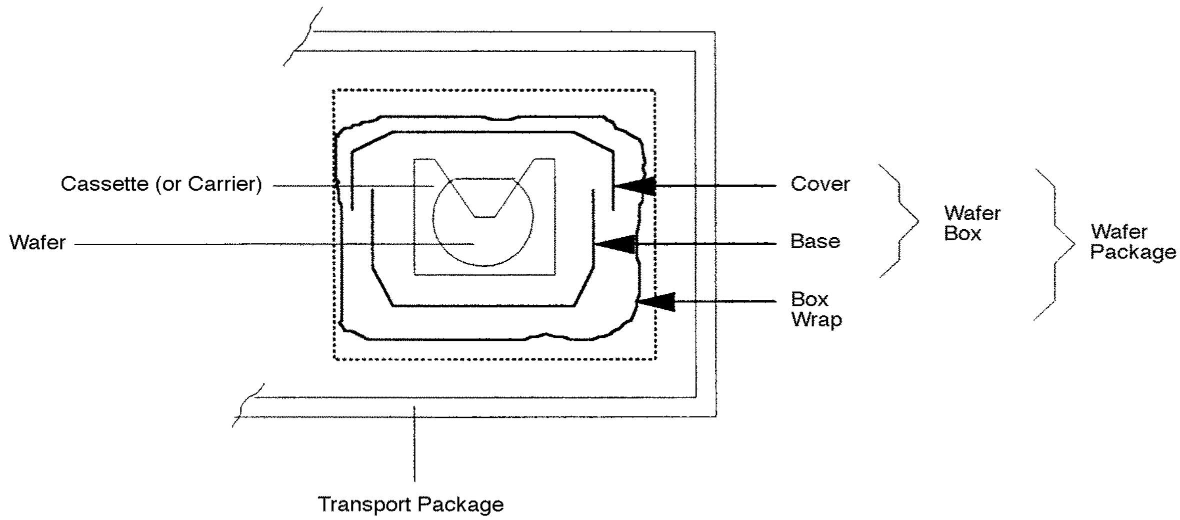
8.1.4 It is recommended that the wafer box cover and the wafer box base each contain a label, so that each will have a label after they have been separated. However, in some cases, space limitations may require that both labels be placed on the same part of the wafer box.

8.2 For FOSBs containing 300 mm wafers, the following requirements apply.

8.2.1 Use two identical Type 3 labels.

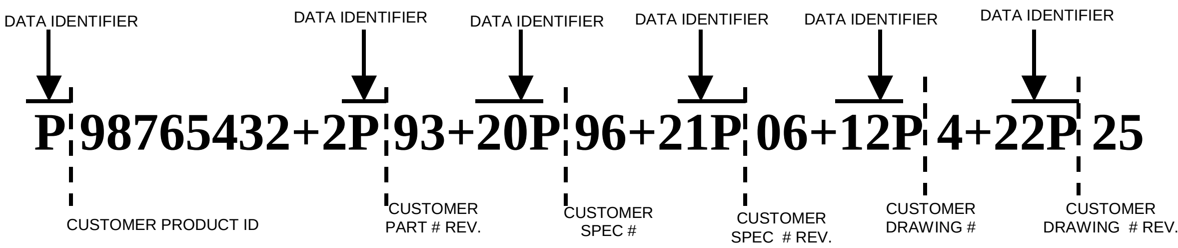
8.2.2 Place one label on the center of the rear surface of the FOSB with the long axis of the label perpendicular to the FOSB base (see Figure 8a).

8.2.3 Place the other, identical, label on the outer wrap bag, which is specified in SEMI M31, at the center of the side adjacent to the FOSB door (see Figure 8b).



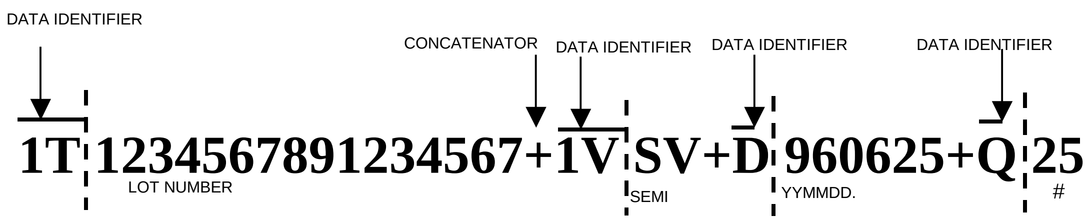
NOTE 1: This specification covers only labels for the wafer package, including the wafer boxes and the wafer box wrap; labels for transport packages are specified in EAI 556-B.

Figure 1
Wafer Box, Wafer Package and Transport Package



NOTE 1: In this figure, vertical dashed lines separate subfields; the concatenation and field identifiers are to the left of these dashed lines. The CUSTOMER PRODUCT ID is a required field whose content is specified by the customer. The PART # REVISION, SPECIFICATION #, SPECIFICATION # REVISION, DRAWING NUMBER and DRAWING NUMBER REVISION are optional fields; these are also assigned by the customer up to a maximum character count of 35, including all concatenation and field identifier characters. All unused character locations are filled with a dash (-).

Figure 2a
Example of Customer Information Field



NOTE 1: In this figure, vertical dashed lines separate subfields; the concatenation and field identifiers are to the left of these dashed lines. LOT NUMBER is assigned by the supplier. SEMI represents the two-character vendor code that is maintained by SEMI. YYMMDD represents the year, month and day of packaging and # is a two-digit number indicating the quantity of wafers in the box.

RELATED INFORMATION 1
MODIFIED DATE FORMAT

NOTE: This related information is not an official part of SEMI T3 and was derived from information developed by the T3 Revision task force of the N.A. Traceability committee during revision of the standard. This related information was approved for publication in June 1997 after full letter ballot and approval by the NA Regional Standards Committee.

R1-1 Alternative Labeling Date Format

R1-1.1 By agreement between supplier and customer, the labeling date may be in the format of YYYYMMDD. The data identifier "6D" should be used when the year is indicated by four characters. This adds three characters to the information printed on the label, two additional date characters and the second character in the data identifier. There is space available on the minimum size label when using the two-dimensional data matrix symbol or the optional Code 128 bar code. Three additional characters added to the Code 39 bar code will not fit on the minimum size label unless the Lot Number is reduced to 13 characters.

SEMI T4-0301
SPECIFICATION FOR 150 mm AND 200 mm POD IDENTIFICATION DIMENSIONS

This specification was technically approved by the Global Physical Interfaces & Carriers Committee and is the direct responsibility of the European Equipment Automation Committee. Current edition approved by the European Regional Standards Committee on December 20, 2000. Initially available at www.semi.org February 2001; to be published March 2001. Originally published in 1995.

1 Purpose

1.1 The purpose of this specification is to ensure dimensional compatibility when mounting pod identification tags and tag identification devices.

2 Scope

2.1 The scope of this specification is to define:

- free space at a pod to allow the mounting of a pod identification tag, and
- free space to allow data transmission.

2.2 This specification is applicable to 150 mm and 200 mm Standard Mechanical Interfaces (SEMI E19). The space required for pod handling per SEMI E47 is considered.

2.3 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This specification applies to pod identification only.

4 Referenced Standards

4.1 *SEMI Standards*

SEMI E15 — Specification for Tool Load Port

SEMI E19 — Standard Mechanical Interface (SMIF)

SEMI E47 — Specification for 150 mm/200 mm Pod Handles

NOTE 1: As listed or revised, all documents cited shall be the latest publications of adopted standards.

5 Terminology

5.1 *pod* — a box having a Standard Mechanical Interface (SMIF) per SEMI E19.

5.2 *Pod Identification Tag* — information carrier mounted to a pod.

5.3 *Standard Mechanical Interface (SMIF)* — interface plane between pod and another minienvironment per SEMI E19.

5.4 *Tag Identification Device* — device for transferring information from/to a pod identification tag.

6 Requirements

6.1 The defined free space for a pod identification tag (see Figure 1) may not be used by any other device than the pod identification tag and its supports.

6.1.1 The pod identification tag and its supports may not exceed the outline of the defined free space for a pod identification tag (see Related Information Section R1-1).

6.2 The defined free space for data transmission (see Figure 1) may only be used by the tag identification device if necessary (see Related Information Section R1-2).

Table 1 Dimensions of Defined Free Space

Dimension	*150 mm SMIF*	*200 mm SMIF*
A1	130 mm	167.5 mm
A2	160 mm min. 180 mm recommended	207.5 mm min. 227.5 mm recommended
A3	70 mm	70 mm
B1	36 mm	36 mm
B2	43 mm	43 mm
B3	120 mm	120 mm

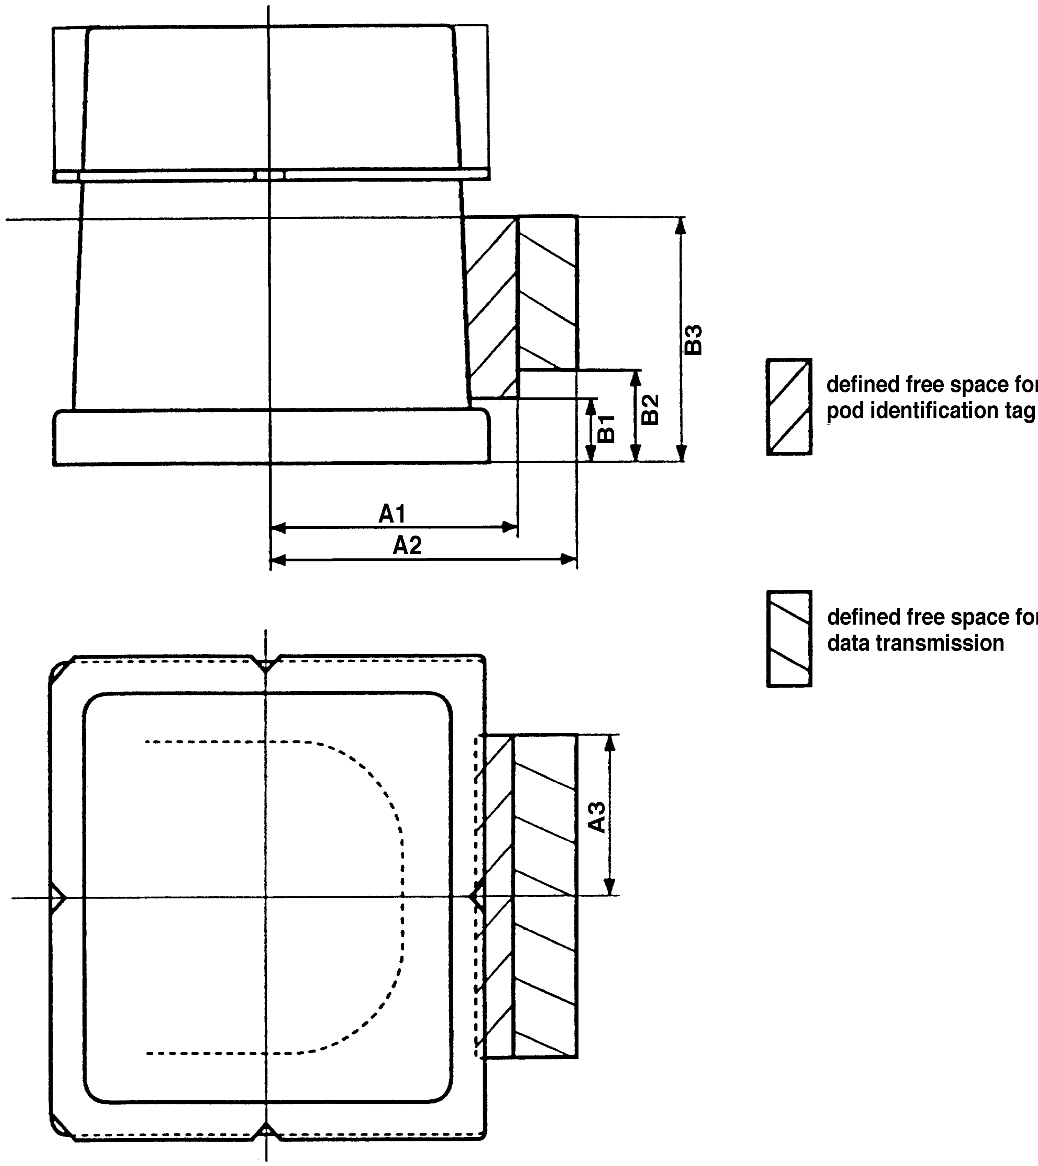

Figure 1

NOTICE: SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials or equipment mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

RELATED INFORMATION 1

NOTE: This related information is not an official part of SEMI T4, but was approved for publication by full letter ballot procedures in 1995.

R1-1 As the outline of the pod sidewall is not standardized, the available space for the pod identification tag may vary between different pod types.

R1-2 The defined free space for data transmission should not be obstructed for the following reasons:

- data transmission
- loading/unloading
- SEMI E15 (multiple row applications)

SEMI T5-96[E]
SPECIFICATION FOR ALPHANUMERIC MARKING OF ROUND GALLIUM ARSENIDE WAFERS

This specification was technically approved by the Global Traceability Committee and is the direct responsibility of the North American Traceability Committee. Current edition approved by the North American Traceability Committee on April 30, 1999. Initially available on SEMI OnLine May 1999; to be published June 1999. Originally published in 1996.

E This document was modified in April 1999 to reflect the creation of SEMI AUX1 as the source for vendor identification codes. Changes were made to numerous sections.

1 Purpose

1.1 The purpose of this document is to define standard criteria for the alphanumeric marking of round gallium arsenide wafers, in order to improve the consistency of wafer marking and allow simplification of the performance requirement of automatic optical character recognition (OCR) equipment.

2 Scope

2.1 This specification defines the geometric and spatial limits of the alphanumeric code, specifically for nominally round, flatted gallium arsenide wafers. It also defines the basic code used to characterize the individual wafer, thereby providing practical operator interpretation. This document does NOT address the marking techniques that may be employed when complying with this standard nor does it address any health issues associated with those techniques.

3 Referenced Documents

3.1 *SEMI Documents*

SEMI AUX1 — List of Vendor Identification Codes

SEMI M12 — Specification for Serial Alphanumeric Marking of the Front Surface of Wafers - Appendix 1, SEMI OCR Standard Character Set

4 Terminology

4.1 *adjacent character misalignment* — the vertical distance, *r*, between the character baselines of two adjacent characters on the same line (see Figure 6).

4.2 *line character misalignment* — the vertical distance, *R*, between the character baselines of any two characters on the same line (see Figure 7).

4.3 *character separation* — the horizontal distance between the adjacent boundaries of any characters (see Figure 1).

4.4 *character spacing* — the horizontal distance between the character spacing reference lines of the adjacent characters (see Figure 1).

4.5 *front surface of the wafer* — the surface upon which active semiconductor devices have been, or will be, fabricated.

NOTE 1: This can be either the V-Groove or Dovetail side of the GaAs wafer.

4.6 *code field (also known as character window)* — the rectangular window within which all characters must be contained (see Figure 4).

4.7 *character skew* — the angle between the character baseline and a line parallel with the bottom of the character window (see Figure 5).

4.8 *character height* — the vertical distance between the lowest and the highest centerpoints of a character.

4.9 *character width* — the horizontal distance between the most left and the most right centerpoint of a character.

5 Shape and Size of Marking

5.1 Dot matrix method shall be used to write characters. The minimum matrix shall be 5 dots horizontal and 9 dots vertical as shown in Figure 1. More dots may be used.

NOTE 2: The 5 × 9 dot matrix shown in Figure 1 is the minimum number of dots allowed. More dots may be used, up to and including a solid line. A solid line is not recommended, since it may increase wafer breakage.

5.2 *Character Dimensions and Spacing* — See Table 1, Table 2, and Figure 1.

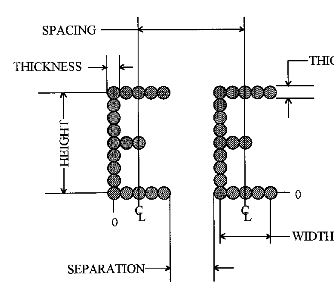

Figure 1

Character Outline

Table 1 Character Dimensions and Spacing — Configuration A — 3”, 100 mm, 125 mm, 150 mm

Character	*(mm)*
Height	1.624 ± 0.025
Width	0.812 ± 0.025
Thickness	0.200 + 0.050 – 0.150
Spacing	1.420 ± 0.025
Minimum Separation	0.400

Table 2 Configuration B — 2”, Option for 3” Wafers

Character	*(mm)*
Height	0.812 ± 0.025
Width	0.406 ± 0.025
Thickness	0.100 ± 0.050
Spacing	0.710 ± 0.025
Minimum Separation	0.104

NOTE 3: The thickness of the diagonal in the letter "N" is 0.138 ± 0.05 mm for single density dot matrix.

5.3 *SEMI OCR Standard Character Set* — See Figure 2 and Appendix 1.

Figure 2

Standard Character Set

6 Alphanumeric Code

6.1 *Code* — Limited to one line of 20 characters maximum (see Figure 3 and Table 3 for an example using 15 characters). The first five to ten characters are an identification number which is unique to the ingot for a given supplier. This is followed by a dash, which is followed by three digits which indicate the wafer number, as numbered starting from the seed end of the ingot. The next two alpha characters identify the vendor according to SEMI AUX1. The last optional characters are specified by the vendor or customer. For example, these characters could be used to differentiate specifications, orientation, or doping. The character string (using a five character ingot as example) is constructed as follows:

Table 3 Vendor identification code

Character #	*Character Style*	*Parameter*	*Definition*
1 - 5	Alphanumeric	Ingot number	Supplier-assigned
6	Alpha	dash	a spacer
7 - 9	Numeric	Wafer number	Number of wafer in ingot
10 - 11	Alpha only	Vendor Identification Code	See SEMI AUX1
12 - 15	Alphanumeric	Optional: characters to identify specification(s)	Supplier- or customer-specified

6.2 If the optional special code characters are used to indicate doping, surface orientation, the symbols shown in Table 4 will be employed.

Table 4 Special Code Characters

Parameter	*Code*	*Definition*
Device surface orientationand flat location	V	V - Groove
	D	Dovetail
Dopant	U	Undoped
	C	Carbon
	R	Chromium
	T	Tellurium
	I	Indium
	S	Silicon
	L	Sulfur
	Z	Zinc
	E	Selenium
Front Surface Orientation	0	100
	A, B	111 A or B
	2	100 (2°off)
	3	100 (other off orientation)
	4	other orientation
	5	other flats

6.3 An example of the code is given in Figure 3.

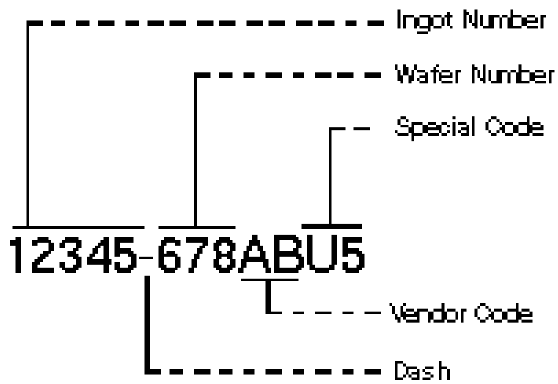

Figure 3

Example of Code for 3" Wafer

7 Code Field Location

7.1 Code field shall be located on the polished front surface of wafers or on the polished or etched back surface of wafers as shown in Table 5.

7.2 Code field is located as shown in Figure 4 and Table 6.

7.3 All characters must be contained within the code field along the major flat. The top of the characters is toward the side of the code field nearest the flat, see Figure 4.

7.4 *Dimensions* — See Figure 4 and Table 6.

7.5 In the standard specification, the first character of the code line is located toward the left side of the code field.

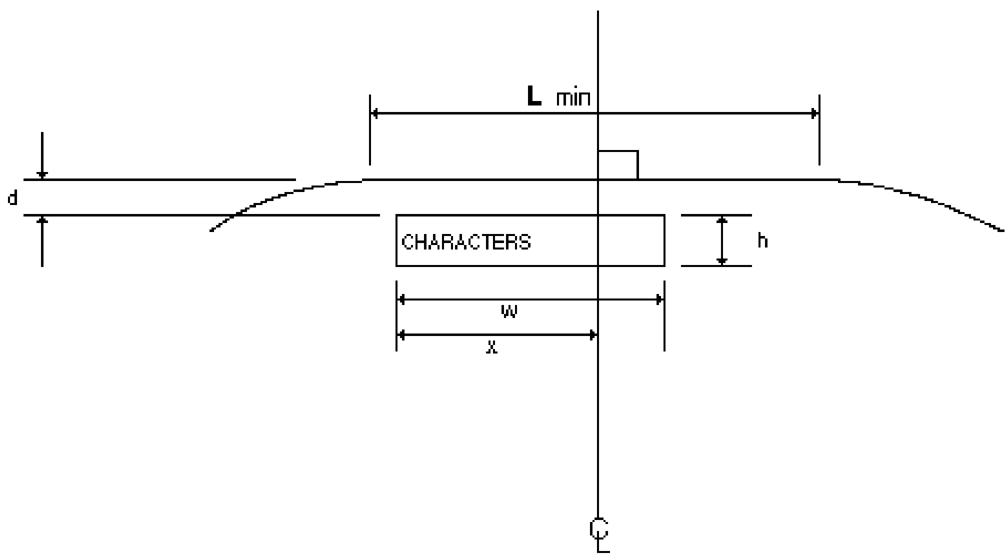

Figure 4

Code Field Location for Flatted Wafers

Table 5 Location of Code Field

Wafer Diameter	*Location of Code Field*
2"	Front (standard); Back surface (alternate)
3"	Front (standard); Back surface (alternate)
100 mm	Front surface
125 mm	Front surface
150 mm	Front surface

Table 6 Code Field Location and Dimensions

Parameter (mm)	*2″*	*3″*	*3″*	*100 mm*	*125 mm*	*150 mm*
Configuration Character Dimension(See Tables 1 and 2)	*B*	*B*	*A**	*A*	*A*	*A*
L min	14.23	19.05	19.05	30.0	40.0	55.0
x	7.1	9.5	9.5	15.0	20.0	27.5
w	14.0	14.0	19.0	27.0	27.0	27.0
d	1.0	1.0	1.0	1.0	1.0	1.0
h	1.4	1.4	2.4	2.4	2.4	2.4

* For 3" wafers, only 13 characters are allowed due to limitations on the size of the code field.

8 Character Alignment

8.1 *Character Skew* — 3 degrees maximum allowable (see Figure 5).

8.2 Maximum character misalignment (see Figures 6 and 7).

8.2.1 Maximum adjacent character misalignment allowable is 0.230 mm.

8.2.2 Maximum line character misalignment allowable is 0.460 mm.

RELATED INFORMATION 1

NOTE: This related information is not an official part of SEMI T5 and is not intended to modify or supercede the official standard. The standard should be referred to in all cases. SEMI makes no warranties or representations as to the suitability of the material set forth herein for any particular application. The determination of the suitability of the material is solely the responsibility of the user.

R1-1 Considerations for Reliable Automatic Reading of the Marking

R1-1.1 The following suggestions are offered to assist in assuring the most reliable automatic reading of the alphanumeric marking.

R1-1.2 *Character Stroke Thickness* — If a 5 × 9 dot matrix is chosen for marking, it is recommended that the minimum dot size be 0.100 mm. Double or higher density dot matrix is recommended; when used, smaller dot diameters may be employed. Stroke thickness should be constant withing 20% over the entire character set so that the reader settings may be optimized for the specific wafer run.

R1-1.3 *Contrast* — The character should have sufficient contrast to be legible. Contrast may be affected by depth and other conditions.

R1-1.4 *Clear Zone* — It is recommended that the area immediately beneath and a minimum of 0.500 mm around the marking characters be of uniform reflectivity and free of any lithography and process overlay edges.

R1-2 Considerations for the Use of Front Surface Markings

R1-2.1 Marks can impinge upon areas where devices may be printed. Since mask geometries are varied, considerations of the mark area should be made in mask design and also when applying the mark specifications to existing mask designs.

R1-2.2 When the mark is applied prior to epitaxial deposition, a crown or epi may grow along the mark edge. The height of this crown will depend upon the epi thickness and the deposition process.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require use of copyrighted material or of an invention covered by patent rights. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights, and the risk of infringement of such rights, are entirely their own responsibility.

SEMI T6-0697[E]

PROCEDURE AND FORMAT FOR REPORTING OF TEST RESULTS BY ELECTRONIC DATA INTERCHANGE (EDI)

This procedure was technically approved by the Global Traceability Committee and is the direct responsibility of the North American Traceability Committee. Current edition approved by the North American Traceability Committee on April 30, 1999. Initially available on SEMI OnLine May 1999; to be published June 1999. Originally published in 1997.

[E] This document was modified in April 1999 to reflect the creation of SEMI AUX1 as the source for vendor identification codes. Changes were made to numerous sections.

1 Purpose

1.1 To facilitate the electronic transfer of quality and test data between users and suppliers.

2 Scope

2.1 This document describes a procedure and format using ANSI ASC X12 "*863 Report of Test Results*" for electronic data interchange (EDI). The ANSI standard provides a basic structure and codes for transmitting messages. This is supplemented by SEMI-generated codes to describe product parameters and test methods specific to the semiconductor industry. For a description of the EDI business applications, see Appendices 1 and 2.

2.2 This standard may be used to report test results for all products used in the semiconductor industry when the applicable codes are included in a SEMI standard. It is intended to provide a consistent method for transmitting test results throughout the industry. Any implementation of this document shall be agreed upon between trading partners.

3 Referenced Documents

3.1 *SEMI Documents*

SEMI AUX1 — List of Vendor Identification Codes

SEMI M12 — Specification for Serial Alphanumeric Marking of the Front Surface of Wafers

SEMI M18 — Format for Silicon Wafer Specification Form for Order Entry

3.2 *ANSI Documents*[1]

ASC X12 — 863 Report of Test Results, version 003 release 050

ASC X12 — Data Dictionary

[1] *American National Standards Institute, 11 West 42nd Street, New York, NY 10036*

4 Terminology

4.1 *Acronyms*

ANSI — American National Standards Institute

ASC X12 (Accredited Standards Committee X12) — Comprised of industry members for the purpose of creating EDI standards for submission to ANSI for subsequent approval and dissemination.

EDI (Electronic Data Interchange) — The computer-to-computer exchange of information which has traditionally been communicated using paper documents.

4.2 *Definitions*

4.2.1 *certificate of analysis EDI message* — one message containing measurement or statistical data for one shipment, from one supplier site to one user site, of one user part number against one user purchase order shipped. Multiple lot numbers may be included in the shipment. (See Appendix 5.)

4.2.2 *codes* — a recognized set of abbreviations or conventions for representing specific elements of data.

4.2.3 *EDI translation* — the conversion of application data to and from the ASC X12 standard format.

4.2.4 *manufacturing lot* — a generic description for a group of parts that have a relationship as defined by the party establishing the identification (e.g., batch, shipment, production run, qualification/test run, individual product). (See Application Notes.)

4.2.5 *mapping* — the process of identifying the standards data element relationship to application data elements.

4.2.6 *message* — entire data stream including the outer envelope.

4.2.7 *statistical results EDI message* — one message containing measurement or statistical data for defined parameters for a stated period of time (see Appendix 5).

4.2.8 *test results EDI message* — used to designate data provided by special request (e.g., engineering, qualifications). This message contains specific measurement or statistical data for one request, from one trading partner to another trading partner, of one part number against one purchase order. Multiple lot numbers may be included. (See Appendix 5.)

4.2.9 *trading partner* — all members within the channels of distribution within an industry (suppliers, carriers, users, and intermediaries)[2] . This includes buyers and sellers which represent SEMI terms of user and supplier as well.

5 Requirements

5.1 An implementation model shall be agreed upon by trading partners. It is the intent of this document to make interpretation of the models used for transmitting electronic messages more consistent, so that implementations are based upon common practices.

5.1.1 Select one of the report types in Table 1 using the business model (Appendix 1) and the definitions found in Section 4.

Table 1 Report Types

Code	*Type of EDI Message*
CA	Certificate of Analysis
RT	Test Results
SR	Statistical Results

5.1.2 Define data requirements representing the requested measurements and statistics that are recorded for reporting electronically. (See Appendix 2.)

5.1.3 Select codes for parameters, units of measure, and statistical terms. Appendix 4 is a guideline to assist in modeling the EDI message. It uses codes selected from the ANSI Data Dictionary as well as codes created by SEMI for the semiconductor industry.

5.1.4 Data is electronically reformatted from the application where it resides into a format suitable for EDI transmission. This usually requires the use of translation software and the development of application interface programs.

5.2 Thorough piloting, testing, and educating is required for successful implementation.

6 Procedures

6.1 See Appendix 4.

[2] *The term "Trading Partner" is referenced from the Global Electronics Guidelines (DRAFT) for Bar Code & 2D Symbol Marking of Products and Packages in Conjunction with EDI.*

7 Application Notes

7.1 Pending ANSI approval, SEMI is an authorized agency to maintain the tables of codes.

7.2 The material contained in Appendix 4 was created by using an EDI simulator referencing the ASC X12 "*863 Report of Test Reports*", version 003 release 050.

7.3 In using Appendix 4, refer to the column "SEMI Use" (far-left) to determine if data element usage is mandatory, conditional, or optional. SEMI mandatory elements include all ASC X12 863 mandatory elements, as well as selected other elements that are optional or conditional within ASC X12 863.

7.4 In Appendix 5, the example messages in this appendix were simplified by showing only a portion of what they can do. In practice, all of the transaction types (CA, RT, and SR) can use any combination of the statistical codes in Appendix 4, the new statistical codes in Appendix 4, or raw measurement data.

7.5 Additional statistical codes are defined in Appendix 3. These codes are pending ANSI approval.

7.6 This procedure will accommodate date/time considerations for the turn of the century. There are many options found in the data transmission segments in this document. The end result for which option is utilized will be agreed upon by the trading partners. The message is itself part of the ANSI standard, and any revisions to this standard will be incorporated.

7.6.1 In the data element type, DT is a standard ANSI definition and is being addressed by ASC X12 Committee.

7.6.2 In the BTR segment, used to identify the date of the actual transmission, BTR06 may be used as a century reference number.

7.6.3 In the DTM segments, used to identify the date for the actual data, the DTM05 data element of CC represents a two-digit century code (e.g., 19 for 1999, 20 for 2000).

7.7 Multiple levels of lot definitions (i.e., Lots and Sub-lots) may be handled through nesting within the LIN loop.

8 Listing of Appendices

8.1 *Appendix 1* — EDI Business Model

8.2 *Appendix 2* — EDI Transmission Flowchart

8.3 *Appendix 3* — New EDI Statistics (Definitions)

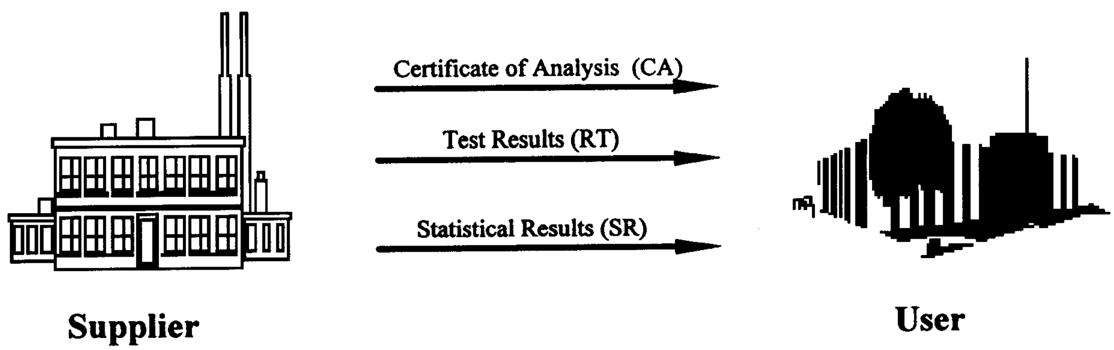
8.4 *Appendix 4* — EDI Transmission Components (863 Report of Test Results)

8.5 *Appendix 5* — Examples of EDI Transmissions

APPENDIX 1
EDI BUSINESS MODEL

NOTE: The material in this appendix is an official part of SEMI T6 and was approved by full letter ballot procedure in March 1997.

A1-1 Any implementation model is agreed upon by trading partners. It is the intent of this document to make interpretation of the models used for transmitting electronic messages more consistent, so that implementations are based upon common practices.



A1-2 Attributes of EDI Messages

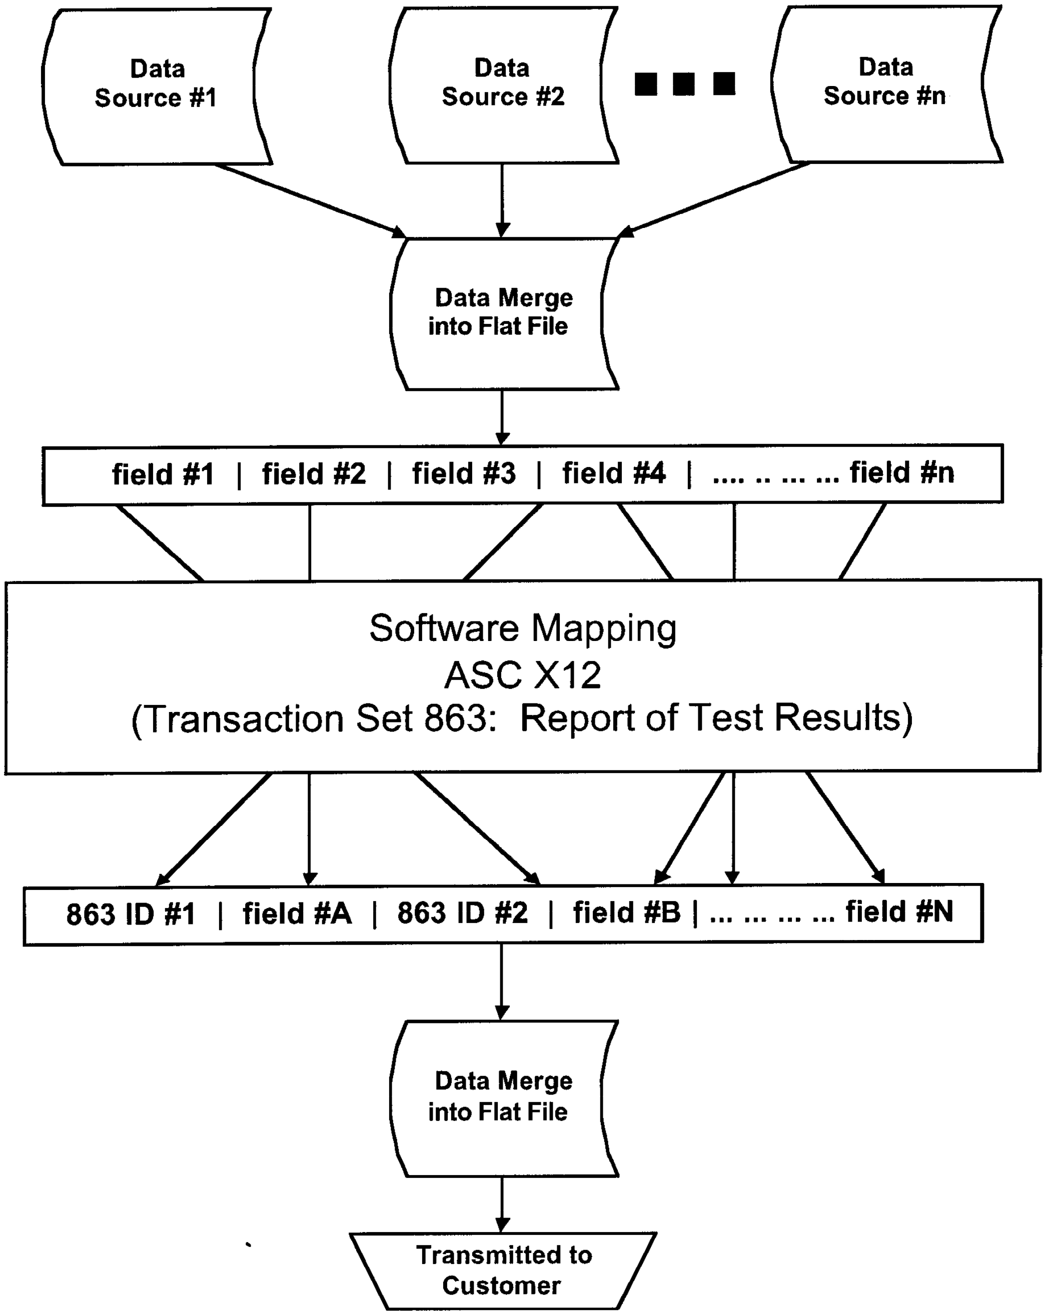
A1-2.1 *Certificate of Analysis (CA)* — One message containing measurement or statistical data for one shipment, from one supplier site to one user site, of one user part number against one user purchase order shipped. Multiple lot numbers may be included in the shipment.

A1-2.2 *Test Results (RT)* — Used to designate data provided by special request (e.g., engineering, qualifications). This message contains specific measurement or statistical data for one request, from one trading partner to another trading partner, of one part number against one purchase order. Multiple lot numbers may be included.

A1-2.3 *Statistical Results (SR)* — One message containing measurement or statistical data for defined parameters for a period of time from one trading partner to another.

APPENDIX 2
EDI TRANSMISSION FLOWCHART

NOTE: The material in this appendix is an official part of SEMI T6 and was approved by full letter ballot procedure in March 1997.



APPENDIX 3
NEW EDI STATISTICS (DEFINITIONS)

NOTE: The material in this appendix is an official part of SEMI T6 and was approved by full letter ballot procedure in March 1997.

A3-1 Additions to ANSI's Statistical Codes to be Included within this Standard

A3-1.1 These new statistical codes are added to a predefined ANSI list of summary statistics found in Appendix 3 under the transaction segment STA. The codes are HS, HW, HC, GM, GS, PK, EC, OC, and PE and are submitted to ANSI for approval. The codes can be used in an EDI message as long as the trading partners agree to include them as part of their transmissions. Once the codes are approved, the ASC X12 convention will be updated to automatically accept these codes as standards.

A3-1.2 *Histogram Information*

A3-1.2.1 **HS** = Histogram Start (Left side of first class or bar)

A3-1.2.2 **HW** = Histogram Class Width (Width of class or bar)

A3-1.2.3 **HC** = Histogram Class Count (Count of classes or bars)

A3-1.3 *Process Capability Information*

A3-1.3.1 **GM = Geometric Mean (GMEAN).** For the lognormal distribution, it's calculated as:

TMEAN = The mean of the natural log of the raw data values

GMEAN = EXP(TMEAN+ (TSIGMA**2)/2)

A3-1.3.2 **GS = Geometric Sigma (GSIGMA).** For the lognormal distribution, it's calculated as:

TSIGMA = The sigma of the natural log of the raw data values

GSIGMA = SQRT((EXP((2*TMEAN)+(TSIGMA**2)))**EXP((TSIGMA**2))-1))

A3-1.3.3 **PK** = The **peak** of the fitted probability distribution function. It's calculated as the maximum Y value of the probability distribution function after it is fitted to the process histogram.

A3-1.3.4 **EC** = The **equivalent normal Cpk (ECPK).** For the lognormal distribution, it's calculated as:

ECPK = ((LN(USL))-LN((GMEAN**2/(SQRT(GMEAN**2+GSIGMA**2))))/ (3*SQRT(LN (GMEAN**2)/ GMEAN**2)))

A3-1.4 *Outlier Information*

A3-1.4.1 **OC = Outlier Count.** It may be calculated as A minus B, where A = the count beyond a chosen sigma point using the histogram, and B = the count beyond the chosen sigma point using the statistical distribution.

A3-1.5 *Percentile Information*

A3-1.5.1 **PE = Percentile.** Like the HG, it can be repeated to give different elements. The user and supplier need to agree on the order for a particular application.

APPENDIX 4
EDI TRANSMISSION COMPONENTS (863 REPORT OF TEST RESULTS)

NOTE: The material in this appendix is an official part of SEMI T6 and was approved by full letter ballot procedure in March 1997.

A4-1 Introduction

A4-1.1 The purpose of this section is to provide the necessary information to enable trading partners to use the ASC X12 standards for the exchange of electronic business documents within the electronics industry.

A4-1.2 The transmission, in the ASC X12 format, is comprised of an outer envelope (transmission envelope) which identifies the sender and receiver. Within the transmission envelope are one or more functional groups.

A4-1.3 The functional groups are analogous to batches of like documents (i.e., certificate of analysis, test results, statistical results). Each functional group contains one or more transaction sets (electronic documents). Each transaction set is an ordered collection of segments. Each segment is an ordered collection of data elements.

A4-1.4 Each segment has been assigned a two or three charac-ter identifier.

A4-1.5 This identifier marks the beginning of each segment. Each element within the segment is separated by a data element separator character. Electronic Industry Data Exchange (EIDX) recommends the use of the asterisk (*) character as a data element separator. A segment terminator character is used to mark the end of a segment.

A4-2 Format

A4-2.1 The ASC X12 segment hierarchy lists all segments, in order, available from the ASC X12 standard. The segment ID's that are shaded indicate the segments utilized by EIDX. Following the ASC X12 segment hierarchy is a detailed description of each segment in the order that they appear in the transaction set.

A4-2.2 Each segment is listed with the segment ID and name, level (header, detail, or summary), loop (if the segment is contained within a loop), loop repeat (for the first segment in the loop), requirement within the transaction set, maximum use, purpose (as defined by ASC X12), ASC X12 syntax notes, ASC X12 comments for segment usage, and notes that explain the EDIX convention for this segment within the transaction set. It is important to note all shaded text is either an EDIX convention or EDIX terminology. Shaded coded lists refer to recommendations culled from the entire ASC X12 data element code list. The unshaded areas contain definitions and comments from the ASC X12 standard.

A4-2.3 The data element summary lists each data element, in order, for the segment; for each data element there is one line to identify reference designator, data element number, data element name, and attributes.

A4-2.4 Below the one line summary are usage notes and ac-tual values identified for use.

A4-2.5 *Reference Designator* — This is the segment identifier with the data element sequence number within the segment.

A4-2.6 *Data Element Number* — This is the number assigned to the data element by ASC X12. This number may be used for direct refer-ence into the ASC X12 Data Dictionary.

A4-2.7 *Data Element Name* — This is the name assigned to the data element by ASC X12, in the ASC X12 Data Dictionary.

A4-2.8 *Attributes* — Each data element has three ANSI attributes: element usage, element type, and Minimum/Maximum length.

A4-2.9 *Element Usage*

M Mandatory Designer

This is the segment identifier with the data element sequence number within the segment.

O Optional

The data element may be used if the segment is used.

X Conditional

The data element may be used only if other elements are used within the segment.

The particular condition/relation will be stated in the Data Element Summary for the segment when used.

A4-2.10 *Element Type*

ID Identifier

Values for the identifier-type data elements are taken from a predefined list in the ASC X12 data element dictionary.

AN String

Values for the string-type data elements are a sequence of any printable characters.

DT Date

Values for a date-type data element are in the format YYMMDD.

TM Time

Values for a time-type data element are in the format HHMM expressed in a 24-hour clock.

Nx Numeric

Values for a numeric data element are in an implied decimal format, where "X" indicates the number of places to the right of the decimal point.

i.e.,

N0 is a whole number (999.)

N2 is 999.99

R Decimal

This is a numeric field in character format, with a decimal point included. It is treated as alpha/numeric. The decimal point is not sent for whole numbers.

e.g.,

to send the number 0128.734, the field would contain "128.734".

to send the number 0789.00, the field would contain "789".

A4-2.11 *Minimum/Maximum*

This is the minimum and maximum length the field can be.

e.g.,

02/02 - fixed length of 2 characters.

04/09 - Minimum length of 4 characters and maximum length of 9 characters.

863 Report of Test Results - Overview

Heading: This section of information appears one time at the beginning of each transaction. The information is targeted at the indentification of "Who is sending What to Whom, Where, and When."

SEMI USE:	*Pos. No.*	*Seg. ID*	*Name*	*Req. Des.*	*Max. Use*	*Loop Repeat*
M	010	ST	Transaction Set Header	M	1	
M	020	BTR	Beginning Segment for Test Results	M	1	
X	040	REF	Reference Numbers (Order & Material Ident.)	O	12	
O	060	PID	Product/Item Description (Commodity ID)	O	200	
			LOOP ID- NI			>1
M	080	N1	Name (Buyer & Seller Company)	O	1	
O	090	N2	Additional Name Information	O	2	
O	100	N3	Address Information	O	2	
O	110	N4	Geographic Location (Buyer & Seller Site)	O	1	
			LOOP ID - PER			>1
O	130	PER	Administrative Communications Contact	O	1	

Detail: This section of information appears as often as necessary during the transaction. The information deals directly with the data specific to the product or process of the supplier.

SEMI USE:	*Pos. No.*	*Seg. ID*	*Name*	*Req. Des.*	*Max. Use*	*Loop Repeat*
			LOOP ID - LIN			>1
M	010	LIN	Item Identification (Primary Data Loop)	O	1

M	242	LM	Code Source Information	O	1	
M	244	LQ	Industry Code	M	>1	

Summary: Transmission segments to mark the end of the transaction set.

SEMI USE:	*Pos. No.*	*Seg. ID*	*Name*	*Req. Des.*	*Max. Use*	*Loop Repeat*
O	005	CTT	Transaction Totals	O	1	
M	010	SE	Transaction Set Trailer	M	1	

Transmission Segments and Data Elements:

Segment:	**ST Transaction Set Header**
Level:	Heading
Loop:	_______
Usage:	Mandatory
Max Use:	1
Purpose:	To indicate the start of a transaction set and to assign a control number.
Semantic Notes:	**1** The transaction set identifier (ST01) used by the translation routines of the interchange partners to select the appropriate transaction set definition (e.g., 810 selects the invoice transaction set).

Data Element Summary

SEMI USE:	*Ref. Des.*	*Data Element*	*Name*	*Attributes*		
M	**ST01**	**143**	**Transaction Set Identifier Code**	**M**	**ID**	**3/3**
			Code uniquely identifying a Transaction Set.			
			863 X12.41 Report of Test Results			
M	**ST02**	**329**	**Transaction Set Control Number**	**M**	**AN**	**4/9**
			Identifying control number that must be unique within the transaction set functional group assigned by the originator for a transaction set.			

Segment: **BTR Beginning Segment for Test Results**
Level: Heading
Loop: _______
Usage: Mandatory
Max Use: 1
Purpose: To indicate the beginning of a test results transaction set.
Semantic Notes:

1 If BTR01 equals 01, 02, 03, 04, 05, 18, or 19, then BTR06 is required to identify the original test report reference number transmitted.

2 BTR02 is the date that this transaction set was created by the sending party.

3 BTR03 is the time that this transaction set was created by the sending party.

4 BTR05 specifies test results report reference number created by the sending party.

Comments: This segment is used to identify date and purpose of the data transmission.

Data Element Summary

SEMI USE:	*Ref. Des.*	*Data Element*	*Name*	*Attributes*		
M	**BTR01**	**353**	**Transaction Set Purpose Code**	**M**	**ID**	**2/2**
			Code identifying purpose of transaction set.			
			00 Original			
			18 Reissue			
M	**BTR02**	**373**	**Date**	**M**	**DT**	**6/6**
			Date (YYMMDD).			
			Seller generated date representing the data collection date or other mutually agreeable date. Not associated with the lot/date code of the material.			
O	**BTR03**	**337**	**Time**	**O**	**TM**	**4/8**
			Time expressed in 24-hour clock time as follows: HHMM or HHMMSS, or HHMMSSD or HHMMSSDD, where H = hours (00-23), M = minutes (00-59), S = integer seconds (00-59) and DD = decimal seconds are expressed as follows: D = tenths (0-9) and DD = hundredths (00-99).			
			Seller generated time representing the data collection time or other mutually agreeable time. Not associated with the lot/date code of the material.			
M	**BTR04**	**755**	**Report Type Code**	**O**	**ID**	**2/2**
			Code indicating the title or contents of a document, report, or supporting item.			
			CA Certificate of Analysis			
			RT Report of Tests and Analysis Report			
			SR Statistical Report			
X	**BTR05**	**127**	**Reference Number**	**O**	**AN**	**1/30**
			Reference number or identification number as defined for a particular Transaction Set, or as specified by the Reference Number Qualifier.			
			Seller's unique shipment identification code visible on the shipping container and/or shipping paperwork that identifies the link to the data in a single Transaction Set. (Examples: Invoice No., Shipper No., Work Order No., etc.)NOTE: In the case of a re-transmittal (Purpose Code 18, reissue) of previous data due to correction or loss of data, this data element repeats the information from the prior transmission to be replaced.			
O	**BRT06**	**127**	**Reference Number**	**O**	**AN**	**1/30**
			Reference number of identification number as defined for a particular Transaction Set, or as specified by the Reference Number Qualifier.			

Segment: **REF Reference Numbers (Order & Material Ident.)**
Level: Heading
Loop: _______
Usage: Optional
Max Use: 12
Purpose: To specify identifying numbers.
Syntax Notes: **1** At least one of REF02 or REF03 is required.
Comments:
1 It is recommended for use and for report types CA and RT.
2 BTR03 is the time that this transaction set was created by the sending party.
3 It is not repeated once for each REF01 Qualifier determined by mutual consent between the Buyer and Seller as required.

Data Element Summary

SEMI USE:	*Ref. Des.*	*Data Element*	*Name*	*Attributes*		
M	**REF01**	**128**	**Reference Number Qualifier**	**M**	**ID**	**2/2**
			Code qualifying the Reference Number.			
			BV Purchase Order Line Item Identifier *(Buyer)*			
			MF Manufacturer's Part Number *(Seller)*			
			PM Part Number *(Buyer)*			
			PO Purchase Order Number *(Buyer)*			
			PP Purchase Order Revision Number *(Buyer)*			
			RE Release Number *(Buyer)*			
			S3 Specification Number *(Buyer)*			
			SZ Specification Revision *(Buyer)*			
			YB Revision Number *(Buyer)*			
			ZZ Mutually Defined			
X	**REF02**	**127**	**Reference Number**	**X**	**AN**	**1/30**
			Reference number or identification number as defined for a particular Transaction Set, or as specified by the Reference Number Qualifier.			
O	**REF03**	**352**	**Description**	**X**	**AN**	**1/80**
			A free-form description to clarify the related data elements and their content.			

Segment: **PID** **Product/Item Description (Commodity ID)**

Level: Heading

Loop: _______

Usage: Optional

Max Use: 200

Purpose: To describe a product or process in coded or free-form format.

Syntax Notes:

1 If PID04 is present, then PID03 is required.

2 At least one of PID04 or PID05 is required.

3 If PID07 is present, then PID03 is required.

Semantic Notes:

1 Use PID03 to indicate the organization that publishes the code list being referred to.

2 PID04 should be used for industry-specific product description codes.

Comments:

1 If PID01 = "F", then PID05 is used. If PID01 = "S", then PID04 is used. If PID01 = "X", then both PID04 and PID05 are used.

2 PID07 specifies the individual code list of the agency specified in PID03.

Data Element Summary

SEMI USE:	*Ref. Des.*	*Data Element*	*Name*		*Attributes*		
M	**PID01**	**349**	**Item Description Type**		**M**	**ID**	**1/1**
			Code indicating the format of a description.				
			F	Free-form			
				Not recommended. To be used prior to adoption of SEMI codes into X.12.41 Standards.			
			S	Structured (From Industry Code List)			
				Preferred use. The PID03 and PID04 codes shall be registered with the appropriate organization.			
			X	Semi-structured (Code and Text)			
				Not recommended.			
M	**PID03**	**559**	**Agency Qualifier Code**		**X**	**ID**	**2/2**
			Code identifying the agency assigning the code values.				
			SM	Semiconductor Equipment and Materials International			
				SEMI EDI Task Force shall register this code with ANSI.			
			ZZ	Mutually Defined			
				To be used prior to adoption of SEMI codes into X.12.41 Std.			
M	**PID04**	**751**	**Product Description Code**		**X**	**AN**	**1/12**
			A code from an industry code list which provides specific data about a product characteristic.				
			For silicon wafers see SEMI Standard M18. Codes for other semiconductor products can be used as they are documented.				
O	**PID05**	**352**	**Description**		**X**	**AN**	**1/80**
			A free-form description to clarify the related data elements and their content.				
O	**PID07**	**822**	**Source Subqualifier**		**O**	**AN**	**1/15**
			A reference that indicates the table or text maintained by the Source Qualifier.				
			Identifies the SEMI Standard and applicable Table or Figure reference that defines the meaning of the codes used in PID04.				

Segment:	**N1 Name (Buyer & Seller Company Ident.)**
Level:	Heading
Loop:	N1
Usage:	Optional
Max Use:	1
Purpose:	To identify a party by type of organization, name, and code.
Syntax Notes:	**1** At least one of N102 or N103 is required.
	2 If either N103 or N104 is present, then the other is required.
Comments:	This N1 loop requires a minimum of two passes, one for Buyer (receiver) identification, and one for Seller (submitter) identification.

Data Element Summary

SEMI USE:	*Ref. Des.*	*Data Element*	*Name*		*Attributes*	
M	**N101**	**98**	**Entity Identifier Code**	**M**	**ID**	**2/2**
			Code identifying an organizational entity, a physical location, or an individual.			
			1X Laboratory			
			28 Subcontractor			
			BY Buying Party (Purchaser)			
			PT Party to Receive Test Report [Buyer to the attention of]			
			SE Selling Party			
			YE Third Party			
X	**N102**	**93**	**Name**	**X**	**AN**	**1/35**
			Free-form name.			
			Use of N103 and N104 in lieu of this Element is recommended.			
X	**N103**	**66**	**Identification Code Qualifier**	**X**	**ID**	**1/2**
			Code designating the system/method of code structure used for Identification Code (67).			
			Preferred use is N103/N104 combination.			
			SM SEMI			
			ZZ Mutually Defined			
X	**N104**	**67**	**Identification Code**	**X**	**AN**	**2/20**
			Code identifying a party or other code.			
			Code from SEMI Standards Buyer/Seller code list (SEMI AUX1).			

Segment: **N2 Additional Name Information**
Level: Heading
Loop: N1
Usage: Optional
Max Use: 2
Purpose: To specify additional names or those longer than 35 characters in length.

Data Element Summary

SEMI USE:	*Ref. Des.*	*Data Element*	*Name*	*Attributes*		
M	**N201**	**93**	**Name** Free-form name.	**M**	**AN**	**1/35**
O	**N202**	**93**	**Name** Free-form name.	**O**	**AN**	**1/35**

Segment: **N3 Address Information**
Level: Heading
Loop: N1
Usage: Optional
Max Use: 2
Purpose: To specify the location of the named party.

Data Element Summary

SEMI USE:	*Ref. Des.*	*Data Element*	*Name*	*Attributes*		
M	**N301**	**166**	**Address Information** Address information	**M**	**AN**	**1/35**
O	**N302**	**166**	**Address Information** Address information	**O**	**AN**	**1/35**

Segment: N4 **Geographic Location (Buyer & Seller Site Ident.)**
Level: Heading
Loop: N1
Usage: Optional
Max Use: 1
Purpose: To specify the geographic place of the named party.
Syntax Notes: **1** If N406 is present, then N405 is required.
Comments: **1** A combination of either N401 through N404 or (N405 and N406) may be adequate to specify a location.
2 N402 is required only if city name (N401) is in the USA or Canada.

Data Element Summary

SEMI USE:	*Ref. Des.*	*Data Element*	*Name*	*Attributes*		
O	**N401**	**19**	**City Name**	**O**	**AN**	**2/30**
			Free-form text for city name.			
O	**N402**	**156**	**State or Province Code**	**O**	**ID**	**2/2**
			Code (Standard State/Province) as defined by appropriate government agency.			
O	**N403**	**116**	**Postal Code**	**O**	**ID**	**3/11**
			Code defining international postal zone code excluding punctuation and blanks (zip code for United States).			
O	**N404**	**26**	**Country Code**	**O**	**ID**	**2/3**
			Code identifying the country.			
X	**N405**	**309**	**Location Qualifier**	**X**	**ID**	**1/2**
			Code identifying type of location.			
			Preferred use if N405/406 combination.Additional codes are available for selection.			
			FA Factory			
O	**N406**	**310**	**Location Identifier**	**O**	**AN**	**1/30**
			Code which identifies a specific location.			
			Mutually defined identification strings shall be determined by trading partners and shall remain constant.			

Segment:	**PER Administrative Communications Contact**
Level:	Heading
Loop:	PER
Usage:	Optional
Max Use:	1
Purpose:	To identify a person or office to whom administrative communications should be directed.
Syntax Notes:	**1** If either PER03 or PER04 is present, then the other is required.
	2 If either PER05 or PER06 is present, then the other is required.
	3 If either PER07 or PER08 is present, then the other is required.
Comments:	Used to notify of change in EDI contact information at Seller, or to specify special attention name at Buyer, as required. Infrequent use anticipated.

Data Element Summary

SEMI USE:	*Ref. Des.*	*Data Element*	*Name*	*Attributes*		
M	**PER01**	**366**	**Contact Function Code**	**M**	**ID**	**2/2**
			Code identifying the major duty or responsibility of the person or group named.			
			DC Delivery Contact			
			[A Buyer attention flag.]			
			EA EDI Coordinator			
			[Seller's EDI primary contact information.]			
			EG Engineering			
			[A Buyer attention flag.]			
			QA Quality Assurance Contact			
			[A Buyer attention flag.]			
			SU Supplier Contact			
			[A Seller attention flag.]			
O	**PER02**	**93**	**Name**	**O**	**AN**	**1/35**
			Free-form name.			
X	**PER03**	**365**	**Communication Number Qualifier**	**X**	**ID**	**2/2**
			Code identifying the type of communication number.			
X	**PER04**	**364**	**Communication Number**	**X**	**AN**	**1/80**
			Complete communications number including country or area code when applicable.			
X	**PER05**	**365**	**Communication Number Qualifier**	**X**	**ID**	**2/2**
			Code Identifying the type of communication number.			
			Refer to 003050 Data Element Dictionary for acceptable code values.			
X	**PER06**	**364**	**Communication Number**	**X**	**AN**	**1/80**
			Complete communications number including country or area code when applicable.			
X	**PER07**	**365**	**Communication Number Qualifier**	**X**	**ID**	**2/2**
			Code identifying the type of communication number.			
			Refer to 003050 Data Element Dictionary for acceptable code values.			
X	**PER08**	**364**	**Communication Number**	**X**	**AN**	**1/80**
			Complete communications number including country or area code when applicable.			
O	**PER09**	**443**	**Contact Inquiry Reference**	**O**	**AN**	**1/20**
			Additional reference number or description to clarify a contact number.			

Segment: **LIN Item Identification (Primary Data Loop)**
Level: Detail
Loop: LIN
Usage: Optional
Max Use: 1
Purpose: To specify basic item identification data.
Syntax Notes: **1** If either LIN04 or LIN05 is present, then the other is required.
Semantic Notes: **1** LIN01 is the line item identification.
Comments: **1** See the Data Dictionary for a complete list of ID's.
2 LIN02 through LIN31 provide for fifteen (15) different product/service ID's for each item. For example: Case, Color, Drawing No., UPC No., ISBN No., Model No., SKU.

Data Element Summary

SEMI USE:	*Ref. Des.*	*Data Element*	*Name*	*Attributes*		
M	**LIN01**	**350**	**Assigned Identification**	**O**	**AN**	**1/11**
			Alphanumeric characters assigned for differentiation within a transaction set.			
			Use to clarify the type of information in Table 2.			
			LOT — Lot Dependent Data			
			Report Type Codes CA and RT: Indicates that the LIN loop contains specific lot based data.			
			PER — Lot Independent Periodic Data			
			Report Type Code SR: Indicates that the LIN loop contains lot independent data.			
M	**LIN02**	**235**	**Product/Service ID Qualifier**	**M**	**ID**	**2/2**
			Code identifying the type/source of the descriptive number used in Product/Service ID (234).			
			KL — Item Management Code			
			Mandatory use for Assigned ID of PER: Primary scope identification number for data, assigned by Seller for the data set included. This Product/Service ID may identify periodic data sets by a single code, permanently defined by mutual consent of trading partners.			
			LT — Lot Identifier			
			Mandatory use for Assigned ID of LOT: Primary lot identification number for material. Example: Polished wafer final acceptance test lot number.			
M	**LIN03**	**234**	**Product/Service ID**	**M**	**AN**	**1/40**
			Identifying number for a product or service.			
X	**LIN04**	**235**	**Product/Service ID Qualifier**	**X**	**ID**	**2/2**
			Code identifying the type/source of the descriptive number used in Product/Service ID (234).			
			NOTE: The codes identified below are examples that may be used for each Product/Service ID Qualifier in this segment. Up to 14 Element pairs (LIN04/LIN05...through LIN30/LIN31) may be used.			
			FE — Feature			
			Optional use for Assigned ID of PER: Secondary scope identification number for data assigned by mutual consent for the data set included. Example: Back Surface Finish No. 2 - Poly, LTO, etc.			

		F1	Finish Number		
			Optional use for Assigned ID of PER: Secondary scope identification number for data, assigned by mutual consent for the data set included. Example: Back Surface Finish No. 1 - Poly, LTO, etc.		
		GC	Grade Code		
			Optional use for Assigned ID of PER: Secondary scope identification number for data, assigned by mutual consent for the data set included. Example: Wafer Grade - Prime (Product), Test/Monitor (Non-product), SIMOX, BESOI, Silicon, Gallium Arsenide, etc.		
		KM	Shelf-Life Code		
		KN	Shelf-Life Action Code		
		LT	Lot Number		
			Optional use for Assigned ID of LOT: Subordinate lot identification number for material. Example: EPI lot number.		
		MB	Measurement Type Code		
			Optional use for Assigned ID of PER: Secondary scope identification number for data, assigned by mutual consent for the data set included. Example: Data is for before or after depositions.		
		PR	Process Number		
			Optional use for Assigned ID of LOT: Additional processing lot identification number for material if required.		
		PW	Part Drawing		
			Optional use for Assigned ID of PER: Secondary scope identification number for data, assigned by mutual consent for the data set included. Example: Specific part number.		
		RS	Set Number		
			Optional use for Assigned ID of LOT: Superior lot identification number for data, assigned by mutual consent for the data set included. Example: Crystal or boule identification, etc.		
		SF	Surface Finish		
			Optional use for Assigned ID of PER: Secondary scope identification number for data, assigned by mutual consent for the data set included. Example: Front Surface Finish - Etch, Polish, EPI, etc.		
		TP	Product Type Code		
			Optional use for Assigned ID of PER: Secondary scope identification number for data, assigned by mutual consent for the data set included. Example: Diameter - 100 mm, 125 mm, 150 mm, 200 mm, 300 mm, etc.		
LIN05	**234**	**Product/Service ID**		**X**	**AN 1/40**
		Identifying number for a product or service.			
		The value identified by the preceding Product/Service ID Qualifier.			

Segment: **QTY Quantity**
Level: Detail
Loop: LIN
Usage: Optional
Max Use: 10
Purpose: To specify quantity information.

Data Element Summary

SEMI USE:	*Ref. Des.*	*Data Element*	*Name*	*Attributes*		
M	**QTY01**	**673**	**Quantity Qualifier**	**M**	**ID**	**2/2**
			Code specifying the type of quantity.			
			39 Shipped Quantity			
M	**QTY02**	**380**	**Quantity**	**M**	**R**	**1/15**
			Numeric value of quantity.			
			Quantity of material represented by the most recent LIN Segment definition above; i.e., the material quantity represented by the data below. Not the combined total quantity of the shipment, unless it is a single lot.			
O	**QTY03**	**355**	**Unit or Basis for Measurement Code**	**O**	**ID**	**2/2**
			Code specifying the units in which a value is being expressed, or manner in which a measurement has been taken.			
			Other codes may be used for other commodities/materials.			
			EA Each			

Segment: **DTM Date/Time Reference**

Level: Detail

Loop: LIN

Usage: Optional

Max Use: 10

Purpose: To specify pertinent dates and times.

Syntax Notes:

1 At lease one of DTM02, DTM03, or DTM06 is required.

2 If either DTM06 or DTM07 is present, then the other is required.

Comments:

1 Report Type Code SR (LIN01 Assigned ID = "PER"): Defines date range covered by summary data.

2 Report Type Codes CA and RT (LIN01 Assigned ID = "LOT"): May be used to specify a ship date or other date mutually agreed upon by Buyer and Seller.

3 If date range for all data entities is identical, the DTM Segment at Position Number 040 may be used to identify a single date.

Data Element Summary

SEMI USE:	*Ref. Des.*	*Data Element*	*Name*	*Attributes*		
M	**DTM01**	**374**	**Date/Time Qualifier**	**M**	**ID**	**3/3**
			Code specifying type of date or time, or both date and time.			
			009 — Process			
			011 — Shipped			
			054 — Sellers Local			
			119 — Test Performed [Period Range]			
			157 — Test Period Start			
			158 — Test Period Ending			
X	**DTM02**	**373**	**Date**	**X**	**DT**	**6/6**
			Date (YYMMDD).			
			Used for start/stop combination.			
O	**DTM03**	**337**	**Time**	**X**	**TM**	**4/4**
			Time expressed in 24-hour clock time (HHMM).			
O	**DTM05**	**624**	**Century**	**O**	**N0**	**2/2**
			The first two characters in the designation of the year (CCYY).			
X	**DTM06**	**1250**	**Date Time Period Format Qualifier**	**X**	**ID**	**2/3**
			Code indicating the date format, time format, or date and time format.			
			RD6 — Range of Dates Expressed in Format YYMMDD-YYMMDD.			
			RD8 — Range of Dates Expressed in Format CCYYMMDD-CCYYMMDD. A range of dates expressed in the format CCYYMMDD-CCYYMMDD, where CCYY is the numerical expression of the century CC and year YY, MM is the numerical expression of the month within the year, and DD is the numerical expression of the day within the year; the first occurrence of CCYYMMDD is the beginning date and the second occurrence is the ending date.			
			RDM — Range of Dates Expressed in Format YYMMDD-MMDD.			
X	**DTM07**	**1251**	**Date Time Period**	**X**	**AN**	**1/35**
			Expression of a date, a time, or range of dates, times, or dates and times.			

Segment: **CID Characteristic/Class ID**

Level: Detail

Loop: CID

Usage: Optional

Max Use: 1

Purpose: To specify the general class or specific characteristic upon which test results are being reported or are to be taken.

Syntax Notes:

1 At least one of CID01, CID02, CID04, or CID05 is required.

2 If either CID03 or CID04 is present, then the other is required.

3 If CID06 is present, then both CID03 and CID04 are required.

4 If CID07 is present, then at least one of CID04 or CID05 is required.

Comments **1** CID06 specifies the individual code list of the agency specified in CID03.

Data Element Summary

SEMI USE:	*Ref. Des.*	*Data Element*	*Name*		*Attributes*	
X	**CID01**	**738**	**Measurement Qualifier**	**X**	**ID**	**1/3**
			Code identifying a specific product or process characteristic to which a measurement applies.			
M	**CID02**	**750**	**Product/Process Characteristic Code**	**X**	**ID**	**2/3**
			Code identifying the general class of a product or process characteristic.			
			13 — Quality (Quality Level)			
X	**CID03**	**559**	**Agency Qualifier Code**	**X**	**ID**	**2/2**
			Code identifying the agency assigning the code values.			
			SM — Semiconductor Equipment and Materials International			
			New code required for SEMI: SM suggested.			
			ZZ — Mutually Defined			
			May be required until incorporation of the SEMI code.			
X	**CID04**	**751**	**Product Description Code**	**X**	**AN**	**1/12**
			A code from an industry code list which provides specific data about a productcharacteristic.			
X	**CID05**	**352**	**Description**	**X**	**AN**	**1/80**
			A free-form description to clarify the related data elements and their content.			
O	**CID06**	**822**	**Source Subqualifier**	**O**	**AN**	**1/15**
			A reference that indicates the table or text maintained by the Source Qualifier.			

Segment: **SPS Sampling Parameters for Summary Statistics**

Level: Detail

Loop: CID

Usage: Optional

Max Use: >1

Purpose: To define the sampling parameters associated with summary statistics.

Syntax Notes:

1 If either SPS05 or SPS06 is present, then the other is required.

Semantic Notes:

1 SPS01 is the population size (count) of the class of objects or events to which the statistical generalizations refer.

2 SPS02 is the sample size, which is the number of observations on which the reported summary statistics were based.

3 SPS03 is the subgroup size, which is the number of observations in a subgroup of a sample.

Data Element Summary

SEMI USE:	*Ref. Des.*	*Data Element*	*Name*	*Attributes*		
O	**SPS01**	**609**	**Count**	**O**	**N0**	**1/9**
			Occurrence counter			
O	**SPS02**	**609**	**Count**	**O**	**N0**	**1/9**
			Occurrence counter			
O	**SPS03**	**609**	**Count**	**O**	**N0**	**1/9**
			Occurrence counter			
O	**SPS04**	**949**	**Confidence Limit**	**O**	**R**	**1/4**
			Percent value expressing the confidence that a true value falls within a certain confidence interval.			
O	**SPS05**	**C00101**	**Composite Unit of Measure**	**X**		
			To identify a composite unit of measure.			
	C00101	**355**	**Unit or Basis for Measurement Code**	**M**	**ID**	**2/2**
			Code specifying the units in which a value is being expressed, or manner in which a measurement has been taken.			
			Refer to 003051 Data Element Dictionary for acceptable code values.			
	C00102	**1018**	**Exponent**	**O**	**R**	**1/15**
			Power to which a unit is raised.			
	C00103	**649**	**Multiplier**	**O**	**R**	**1/10**
			Value to be used as a multiplier to obtain a new value.			
			C00101 through C00103 can be repeated five times using C00103 to C00115.			
O	**SPS06**	**942**	**Sample Frequency Value per Unit of Measurement Code**	**X**	**N0**	**1/9**
			The number of samples collected.			

Segment: **DTM Date/Time Reference**

Level: Detail

Loop: CID

Usage: Optional

Max Use: 10

Purpose: To specify pertinent dates and times.

Syntax Notes:

1 At lease one of DTM02, DTM03, or DTM06 is required.

2 If either DTM06 or DTM07 is present, then the other is required.

Comments:

1 Report Type Code SR (LIN01 Assigned ID = "PER"): Defines date range covered by summary data.

2 Report Type Codes CA and RT (LIN01 Assigned ID = "LOT"): May be used to specify a ship date or other date mutually agreed upon by Buyer and Seller.

3 If date range for all data entities is identical, the DTM Segment at Position Number 040 may be used to identify a single date.

Data Element Summary

SEMI USE:	*Ref. Des.*	*Data Element*	*Name*		*Attributes*	
M	**DTM01**	**374**	**Date/Time Qualifier** Code specifying type of date or time, or both date and time. 009 Process 011 Shipped 054 Sellers Local 119 Test Performed [Period Range] 157 Test Period Start 158 Test Period Ending	**M**	**ID**	**3/3**
X	**DTM02**	**373**	**Date** Date (YYMMDD).	**X**	**DT**	**6/6**
O	**DTM03**	**337**	**Time** Time expressed in 24-hour clock time (HHMM).	**X**	**TM**	**4/4**
O	**DTM05**	**624**	**Century** The first two characters in the designation of the year (CCYY).	**O**	**N0**	**2/2**
X	**DTM06**	**1250**	**Date Time Period Format Qualifier** Code indicating the date format, time format, or date and time format. RD6 Range of Dates Expressed in Format YYMMDD-YYMMDD. RD8 Range of Dates Expressed in Format CCYYMMDD-CCYYMMDD. A range of dates expressed in the format CCYYMMDD-CCYYMMDD where CCYY is the numerical expression of the century CC and year YY, MM is the numerical expression of the month within the year, and DD is the numerical expression of the day within the year; the first occurrence of CCYYMMDD is the beginning date and the second occurrence is the ending date. RDM Range of Dates Expressed in Format YYMMDD-MMDD.	**X**	**ID**	**2/3**
X	**DTM07**	**1251**	**Date Time Period** Expression of a date, a time, or range of dates, times, or dates and times.	**X**	**AN**	**1/35**

Segment:	**MEA Measurements**
Level:	Detail
Loop:	MEA
Usage:	Optional
Max Use:	1
Purpose:	To specify physical measurements or counts, including dimensions, tolerances, variances, and weights. (See figures in appendix for example of use of C001.)
Syntax Notes:	**1** At lease one of MEA03, MEA05, MEA06, or MEA08 is required.
	2 If MEA05 is present, then MEA04 is required.
	3 If MEA06 is present, then MEA04 is required.
	4 If MEA07 is present, then at least one of MEA03, MEA05, or MEA06 is required.
	5 Only one of MEA08 or MEA03 may be present.
Semantic Notes:	**1** MEA04 defines the unit of measure for MEA03, MEA05, and MEA06.
Comments:	**1** When citing dimensional tolerances, any measurement requiring a sign (+ or -), or any measurement where a positive (+) value cannot be assumed, use MEA05 as the negative (-) value and MEA06 as the positive (+) value.

Data Element Summary

SEMI USE:	*Ref. Des.*	*Data Element*	*Name*		*Attributes*	
O	**MEA01**	**737**	**Measurement Reference ID Code**	**O**	**ID**	**2/2**
			Code identifying the broad category to which a measurement applies.			
			Examples of possible values for wafers, if used, are indicated.			
			AV — Average Reading			
			CT — Counts			
			DE — Defects			
			EL — Electrical Characteristics			
			FD — Finished Dimensions Dimensions of the final or end-use product			
			HR — Historical Result			
			IR — Interpolated Result A test result value calculated by interpolation between two physical tests.			
			LS — Lot Status			
			LT — Lot Limits Limits set on test results from all product contained in a single shipment (which may involve any multiple or fraction of transportation carrier units) to one customer.			
			PD — Physical Dimensions (Product Ordered)			
			SF — Shelf Life			
			TR — Test Results Indicates that the data to follow are the results test measurements.			
O	**MEA02**	**738**	**Measurement Qualifier**	**O**	**ID**	**1/3**
			Code identifying a specific product or process characteristic to which a measurement applies.			
			Use not recommended for wafers. Included as optional for use with other commodities/materials.			
			Refer to 003050 Data Element Dictionary for acceptable code values.			

X	**MEA03**	**739**	**Measurement Value** The value of the measurement.	**X**	**R**	**1/20**
X	**MEA04**	**C001**	**Composite Unit of Measure** To identify a composite unit of measure (see figures in appendix for examples of use).	**X**		
M	**C00101**	**355**	**Unit or Basis for Measurement Code** Code specifying the units in which a value is being expressed, or manner in which a measurement has been taken. ZZ Mutually Defined Standardized default unit of measure for each parameter to be published by SEMI as part of the procedure. Optionally, standard code set may be used.	**M**	**ID**	**2/2**
O	**C00102**	**1018**	**Exponent** Power to which a unit is raised.	**O**	**R**	**1/15**
O	**C00103**	**649**	**Multiplier** Value to be used as a multiplier to obtain a new value.	**O**	**R**	**1/10**
X	**MEA05**	**740**	**Range Minimum** The value specifying the minimum of the measurement range.	**X**	**R**	**1/20**
X	**MEA06**	**741**	**Range Maximum** The value specifying the maximum of the measurement range.	**X**	**R**	**1/20**
O	**MEA07**	**935**	**Measurement Significance Code** Code used to benchmark, qualify, or further define a measurement value. 03 Approximately 04 Equal to 05 Greater than or equal to 06 Greater than 07 Less than 08 Less than or equal to 10 Not equal to 22 Actual 31 Calculated 39 Corrected 40 Uncorrected 43 Intermediate 44 Average [based on an average parameter or standard]	**O**	**ID**	**2/2**
X	**MEA08**	**936**	**Measurement Attribute Code** Code used to express an attribute response when a numeric measurement value cannot be determined. Other codes available. 05 Undetectable 09 Pass 12 OK 21 Checked 23 Absent 29 To Be Determined 44 Not Applicable 45 Not Determined 51 Conforming	**X**	**ID**	**2/2**

Segment:	**REF** **Reference Numbers**
Level:	Detail
Loop:	MEA
Usage:	Optional
Max Use:	10
Purpose:	To specify identifying numbers.
Syntax Notes:	**1** At lease one of REF02 or REF03 is required.
Comments:	May be used when describing serialized or positional-dependent data.

Data Element Summary

SEMI USE:	*Ref. Des.*	*Data Element*	*Name*		*Attributes*	
M	**REF01**	**128**	**Reference Number Qualifier**	**M**	**ID**	**2/2**
			Code qualifying the Reference Number.			
			55 — Sequence Number			
			6K — Zone			
			Wafer site or other measurement location identification.			
			BG — Beginning Serial Number			
			EG — Ending Serial Number			
			QQ — Unit Number			
			Used to identify the parameter sample size.			
			SE — Serial Number			
			Serialization reference number applicable to the measurement.			
			SJ — Set Number			
			Reference to the laser mark on a wafer (verbatim).			
X	**REF02**	**127**	**Reference Number**	**X**	**AN**	**1/30**
			Reference number or identification number as defined for a particular Transaction Set, or as specified by the Reference Number Qualifier.			
X	**REF03**	**352**	**Description**	**X**	**AN**	**1/80**
			A free-form description to clarify the related data elements and their content.			

Segment: **STA Statistics**
Level: Detail
Loop: STA
Usage: Optional
Max Use: 1
Purpose: To provide summary statistics related to a specific collection of test result values.

Data Element Summary

SEMI USE:	*Ref. Des.*	*Data Element*	*Name*	*Attributes*		
M	**STA01**	**950**	**Statistic Code**	**M**	**ID**	**2/2**
			A code specifying the specific statistic being reported.			
			Complete list from Standard is available. Typical parameters are indicated. Other parameters may be defined to accommodate proprietary statistical formats.			

01	Cusum Delta
02	Cusum - H
03	Cusum - K
04	Capability Ratio
05	F - Test
06	Control Limit Lower - Individual
07	Control Limit Upper - Individual
08	T - Test
09	Grand Average (Double X-Bar)
10	Kurtosis
11	Mean Average
12	Median
13	Minimum Average
14	Median Range
15	Maximum Average
16	Process Capability Upper
17	Process Capability Lower
18	Process Capability CPK
19	Range Average (R-Bar)
20	Control Limit Lower R-Bar
21	Control Limit Upper R-Bar
22	Range Value (Total Range)
23	Standard Deviation
24	Standard Error
25	Skewness
26	Control Limit Lower X-Bar
27	Control Limit Upper X-Bar
28	Failure Rate in Time (failures over time determined by the equation (failure rate*10^9))
29	Mode
30	Average

			31	Mean			
			32	Minimum Value The least or smallest value; the allowed lower limit			
			33	Maximum Value The largest value; the allowed upper limit			
			AD	Anderson Darling Test			
			CF	Cochran's Procedure			
			CS	Chi-Square Test			
	See Appendix 2		EC	Equivalent Cpk (Add definition)			
	See Appendix 2		PE	Percentile			
	See Appendix 2		GM	Geometric Mean			
	See Appendix 2		GS	Geometric Sigma			
			HG	Histogram			
	See Appendix 2		HC	Histogram Class Count (Count of classes or bars)			
	See Appendix 2		HS	Histogram Start (Left side of first class or bar)			
	See Appendix 2		HW	Histogram Width (Width of class or bar)			
			KS	Kolmogrov-Smirnov Test			
	See Appendix 2		OC	Outlier Count			
	See Appendix 2		PK	Peak Value of Distribution Curve			
			SK	Moment Tests, Skewness and Kurtosis (Weighted Average)			
			SW	Shapiro-Wilk Test			
			ZZ	Mutually Defined			
M	**STA02**	**739**	**Measurement Value** The value of the measurement.		**M**	**R**	**1/20**
O	**STA03**	**C001**	**Composite Unit of Measure** To identify a composite unit of measure (see figures in appendix for example of use).		**O**		
M	**C00101**	**355**	**Unit or Basis for Measurement Code** Code specifying the units in which a value is being expressed, or manner in which a measurement has been taken. Refer to 003050 Data Element Dictionary for acceptable code values.		**M**	**ID**	**2/2**
O	**C00102**	**1018**	**Exponent** Power to which a unit is raised.		**O**	**R**	**1/15**
O	**C00103**	**649**	**Multiplier** Value to be used as a multiplier to obtain a new value.		**O**	**R**	**1/10**
O	**STA04**	**738**	**Measurement Qualifier** Code identifying a specific product or process characteristic to which a meas. applies. Refer to 003050 Data Element Dictionary for acceptable code values.		**O**	**ID**	**1/3**
O	**STA05**	**737**	**Measurement Reference ID Code** Code identifying the broad category to which a measurement applies.		**O**	**ID**	**2/2**
			HR	Historical Result			
			LS	Lot Status			
			LT	Lot Limits Limits set on test results from all product contained in a single shipment (which may involve any multiple or fraction oftransportation carrier units) to one customer.			
			TS	Single Test Limits			

Limits set on each measurement of the specified productcharacteristic or manufacturing process so that any single test whose value falls outside these limits causes the product or process to be declared out-of-specification.

O	**STA06**	**740**	**Range Minimum**	**O**	**R**	**1/20**
			The value specifying the minimum of the measurement range.			
O	**STA07**	**741**	**Range Maximum**	**O**	**R**	**1/20**
			The value specifying the maximum of the measurement range.			

Segment: **REF Reference Numbers**

Level: Detail

Loop: STA

Usage: Optional

Max Use: 10

Purpose: To specify identifying numbers.

Syntax Notes: **1** At lease one of REF02 or REF03 is required.

Data Element Summary

SEMI USE:	*Ref. Des.*	*Data Element*	*Name*	*Attributes*		
M	**REF01**	**128**	**Reference Number Qualifier**	**M**	**ID**	**2/2**
			Code qualifying the Reference Number.			
			Refer to 003050 Data Element Dictionary for acceptable code values.			
X	**REF02**	**127**	**Reference Number**	**X**	**AN**	**1/30**
			Reference number or identification number as defined for a particular Transaction Set, or as specified by the Reference Number Qualifier.			
X	**REF03**	**352**	**Description**	**X**	**AN**	**1/80**
			A free-form description to clarify the related data elements and their content.			

Segment: **TSP** **Test Period or Interval**
Level: Detail
Loop: TSP
Usage: Optional
Max Use: 1
Purpose: To describe a specific period or interval at which tests are performed.
Syntax Notes: **1** If either TSP03 or TSP04 is present, then the other is required.
Comments: **1** TSP02 is used to further expand TSP01 as a qualifier.

Data Element Summary

SEMI USE:	*Ref. Des.*	*Data Element*	*Name*		*Attributes*		
M	**TSP01**	**1312**	**Test Period or Interval Qualifier**		**M**	**ID**	**2/2**
			Code indicating the type of period or interval as related to when a test event occurs.				
			TF	Final Test Measurement or Read-point (Cumulative).			
				This code marks the end of the experiment under a specific test.			
			TI	Intermediate Test Measurements or Read-point (Cumulative).			
				There may be a number of intermediate test points during an experiment; this code would likely be combined with DE 350 to indicate which intermediate test point it is.			
			TO	Initial Test Measurement or Read-point (Cumulative).			
				This is the first test interval that a product or item is subjected to.			
O	**TSP02**	**350**	**Assigned Identification**		**O**	**AN**	**1/11**
			Alphanumeric characters assigned for differentiation within a transaction set.				
X	**TSP03**	**1313**	**Test Period or Interval Value**		**X**	**N0**	**1/6**
			Numeric value of period or interval signifying when a test event occurs.				
X	**TSP04**	**344**	**Unit of Time Period or Interval**		**X**	**ID**	**2/2**
			Code indicating the time period or interval.				
			AD	Average Daily			
			AM	Average Monthly			
			AY	Average Year			
			CY	Calendar Year			
			DA	Calendar Days			
			F1	Fiscal Year Plus One Year			
			F2	Fiscal Year Plus Two Years			
			FY	Fiscal Year			
			MO	Month			
			PR	Preceding Six Months			
			Q1	First Quarter			
			Q2	Second Quarter			
			Q3	Third Quarter			
			Q4	Fourth Quarter			
			QY	Quarter of a Year			
			SA	Semiannual			
			WK	Weeks			
			WW	Work Week			

Segment: **LM Code Source Information**
Level: Detail
Loop: LM
Usage: Optional
Max Use: 1
Purpose: To transmit standard code list identification information.
Comments: **1** LM02 identifies the applicable industry code list source information.

Data Element Summary

SEMI USE:	*Ref. Des.*	*Data Element*	*Name*	*Attributes*		
M	**LM01**	**559**	**Agency Qualifier Code**	**M**	**ID**	**2/2**
			Code identifying the agency assigning the code values.			
			SM Semiconductor Equipment and Materials International			
			ZZ Mutually Defined			
O	**LM02**	**822**	**Source Subqualifier**	**O**	**AN**	**1/15**
			A reference that indicates the table or text maintained by the Source Qualifier.			

Segment:	**LQ Industry Code**
Level:	Detail
Loop:	LM
Usage:	Mandatory
Max Use:	>1
Purpose:	Code to transmit standard industry codes.
Syntax Notes:	**1** If LQ01 is present, then LQ02 is required.
Comments:	This section will allow for a breakdown of the measurement or parameter (e.g., Flatness, STIR, Font Ref, 90% PUA, ADE7700).

Data Element Summary

SEMI USE:	*Ref. Des.*	*Data Element*	*Name*	*Attributes*		
O	**LQ01**	**1270**	**Code List Qualifier Code** Code identifying a specific industry code list. Refer to 003050 Data Element Dictionary for acceptable code values.	**O**	**ID**	**1/3**
M	**LQ02**	**1271**	**Industry Code** Code indicating a code from a specific industry code list. Repeat as necessary to define a parameter in mutlitier fashion. May also be used after parameter definition to provide additional information such as test method orconditions coding.	**X**	**AN**	**1/20**

Segment: **CTT Transaction Totals**
Level: Summary
Loop: _______
Usage: Optional
Max Use: 1
Purpose: To transmit a hash total for a specific element in the transaction set.
Syntax Notes:
1 If either CTT03 or CTT04 is present, then the other is required.
2 If either CTT05 or CTT06 is present, then the other is required.
Comments:
1 This segment is intended to provide hash totals to validate transaction completeness andcorrectness.

Data Element Summary

SEMI USE:	*Ref. Des.*	*Data Element*	*Name*	*Attributes*		
M	**CTT01**	**354**	**Number of Line Items**	**M**	**N0**	**1/6**
			Total number of line items in the transaction set.			
M	**CTT02**	**347**	**Hash Total**	**O**	**R**	**1/10**
			Sum of values of the specified data element. All values in the data element will be summed without regard to decimal points (explicit or implicit) or signs. Truncation will occur on the left most digits if the sum is greater than the maximum size of the hash total of the data element.			
			Example:			
			-.0018 First occurrence of value being hashed. .18 Second occurrence of value being hashed. 1.8 Third occurrence of value being hashed. 18.01 Fourth occurrence of value being hashed. ------- 1855 Hash total prior to truncation. 855 Hash total after truncation to three-digit field.			

Segment: **SE Transaction Set Trailer**

Level: Summary

Loop: _______

Usage: Mandatory

Max Use: 1

Purpose: To indicate the end of the transaction set and provide the count of the transmitted segments (including the beginning (ST) and ending (SE) segments).

Comments: **1** SE is the last segment of each transaction set.

Data Element Summary

SEMI USE:	*Ref. Des.*	*Data Element*	*Name*	*Attributes*		
M	**SE01**	**96**	**Number of Included Segments**	**M**	**N0**	**1/10**
			Total number of segments included in a transaction set including ST and SE segments.			
M	**SE02**	**329**	**Transaction Set Control Number**	**M**	**AN**	**4/9**
			Identifying control number that must be unique within the transaction set functional group assigned by the originator for a transaction set.			

APPENDIX 5
EXAMPLES OF EDI TRANSMISSIONS

NOTE: This appendix was approved as an official part of SEMI T6 by full letter ballot procedure in March 1997.

A5-1 Certificate of Analysis Transmission

The "ISA" and "GS" segments indicated at the start of this example and the "GE" and "IEA" segments located at the end are generally handled by the Information System (IS) dept. in charge of managing the translation and routing of EDI messages through various VAN channels, and are not part of this document.

```

NOTE for Application: For easy visualization and a show of flexibility, the example messages in this appendix were simplified by showing only a portion of what they can do. In practice, all of the transaction types (CA, RT, and SR) can use any combination of the statistical codes in Appendix 4, the new statistical codes in appendix 4, or raw measurement data.

SEMI T7-0302
SPECIFICATION FOR BACK SURFACE MARKING OF DOUBLE-SIDE POLISHED WAFERS WITH A TWO-DIMENSIONAL MATRIX CODE SYMBOL

This specification was technically approved by the Global Traceability Committee and is the direct responsibility of the North American Traceability Committee. Current edition approved by the North American Traceability Committee on January 11, 2002. Initially available at www.semi.org February 2002; to be published March 2002. Originally published in 1997.

1 Purpose

1.1 This specification is intended to provide a marking symbology that can be used to mark silicon wafers with no intrusion into the fixed quality area of the wafer.

2 Scope

2.1 This specification defines the geometric and spatial relationships and content (including the error checking and correcting code) of a rectangular two-dimensional (2-D), machine-readable, binary data matrix code symbol for back surface marking of notched, double-side polished wafers of silicon which comply with SEMI M28, and other materials with diameters of 300 mm and larger. It may be used in conjunction with the alphanumeric marking codes specified in SEMI M12 and SEMI M13 or the bar code specified in SEMI T1.

2.2 Although this specification does not specify the marking techniques that may be employed when complying with its requirements, it is assumed that the symbol will be obtained by laser scribing individual dots.

2.3 The matrix code is applicable to a broad range of wafer products including epitaxial wafers, SOI wafers, and unpatterned or patterned polished wafers. The format and algorithms of this code are based on two-dimensional symbology specified in AIM International Symbology Specification-Data Matrix.

SEMI M28 — Specification for Developmental 300 mm Diameter Polished Single Crystal Silicon Wafers

SEMI T1 — Specification for Back Surface Bar Code Marking of Silicon Wafers

3.2 *AIM International Technical Specification*[1]

AIM/ANSI BC11 — International Symbology Specification — Data Matarix

3.3 *ANSI Standards* [2]

ANSI MH10.8.2 — Data Application Identifier Standard

ANSI X3.4-1986 — American Standard Code for Information Interchange (ASCII)

NOTE 1: This standard is equivalent to ISO 646, Information Processing – ISO 7-bit Coded Character Set for Information Exchange.

4 Terminology

4.1 *alignment bar, of a data matrix code symbol* — a solid line of contiguous filled cells abutting a line of alternately filled and empty cells [AIM - Data Matrix].

4.2 *binary values* — a dot in the wafer surface indicates the binary value 1. The absence of a dot, or a smooth surface surrounding a cell center point indicates the binary value 0.

4.3 *border column* — the outermost column of a data matrix code symbol. This column is a portion of the finder pattern.

4.4 *border row* — the outermost row of a data matrix code symbol. This row is a portion of the finder pattern.

4.5 *cell, of a data matrix code symbol* — the area within which a dot may be placed to indicate a binary value.

4.6 *cell center point, of an array* — the point at which the centerline of a row intersects the centerline of a column.

4.7 *cell spacing, of an array* — the (equal) vertical or horizontal distance between the cell center points of contiguous cells.

1 AIM International Inc., 634 Alpha Drive, Pittsburgh, MO 15238-2802. Website: http://www.aimusa.org

2 American National Standards Institute, 11 West 42nd Street, New York, NY 10036, tel.: 212-642-4900, fax: 212-398-0023.

4.8 *center line, of a row or column* — the line positioned parallel to, and spaced equally between, the boundary lines of the row or column.

4.9 *central area, of a cell* — the area enclosed by a circle centered at the cell center point; used by code readers to sense the binary value of the cell.

4.10 *data matrix code symbol* — a two-dimensional array of square cells arranged in contiguous rows and columns. In certain ECC200 symbols, data regions are separated by alignment patterns. The data region is surrounded by a finder pattern [AIM - Data Matrix].

4.11 *dot* — a localized region with a reflectance which differs from that of the surrounding surface.

NOTE 2: To assure reading efficiency, a minimum contrast of 30% is required between the reflectance value of a dot and the surrounding wafer surface. Various densitometers can provide such measurements nondestructively.

4.12 *dot misalignment, within a cell* — the distance between the physical center point of a dot and the cell center point.

4.13 *finder pattern, of a data matrix code symbol* — a perimeter to the data region. Two adjacent sides contain dots in every cell; these are used primarily to define physical size, orientation and symbol distortion. The two opposite sides are made up of cells containing dots in alternate cells [AIM Data Matrix].

4.14 *reference point, of a data matrix code symbol* — the physical center point of a corner cell common to the primary border row and the solid line of the alignment bar, used to identify the physical location of the symbol on the object being marked with the symbol.

NOTE 3: The reference point is at a fixed location on the object. Different cells may be chosen as the reference point depending on the desired orientation of the symbol on the object and the size variability of the symbol. The particular cell to be used as the reference point must be specified for each application.

5 Requirements

5.1 *Shape and Size of the Data Matrix Code Symbol*

5.1.1 *Data Matrix Code Symbol Dimensions*

5.1.1.1 Each rectangular matrix code symbol shall be composed of an array of 8 rows and 32 columns with an alignment bar as defined in AIM ISS Data Matrix.

5.1.1.2 Cell spacing shall be 125 µm, center to center.

5.1.2 *Dot Size* — The nominal shape of the dot produced in the matrix may be circular or square. Its diameter or edge length (after polishing) shall be 100 µm + 10 µm – 20 µm.

5.1.3 *Border Rows and Columns*

5.1.3.1 One border row and one border column shall contain a dot in each cell. These are identified as the primary border row and the primary border column. These are used by the code reader to determine the orientation of the matrix.

5.1.3.2 The opposing (secondary) border row and column shall contain dots in alternating cells.

5.1.3.3 For these rectangular matrix code symbols, the reference point of the symbol shall be the physical centerpoint of the cell common to the primary border row and the center alignment bar.

5.1.4 The maximum dot misalignment within a cell is 15 µm. This ensures that a minimum size dot covers a cell central area of radius 25 µm.

5.1.5 Adjacent dots shall not touch.

5.2 *Content of the Data Matrix Code Symbol*

5.2.1 Each rectangular matrix code symbol shall contain 10 message characters, together with the error checking and correcting (ECC200) code characters, encoded in accordance with AIM ISS-Data Matrix.

5.2.2 The message characters may include any of those designated as “mostly upper case” in AIM ISS-Data Matrix, in Table 5 and Annex J. The ten message characters shall contain two elements:

a. a vendor-assigned 8-character wafer identification code, followed by

b. a 2-character vendor identification code (see SEMI AUX1).

5.3 *Location of the Data Matrix Code Symbol*

5.3.1 With the wafer positioned back surface up and with the primary fiducial toward the operator, the origin of the data matrix code symbol shall be located as specified below.

5.3.1.1 The 8 row x 32 column rectangular 2-D matrix code symbol shall be placed entirely outside a fixed quality area (FQA) with a nominal edge exclusion of 3 mm. The reference point shall be located 148.95 ± 0.15 mm from the center of the wafer, along a radius 5.0 ± 0.1° counterclockwise from the axis of the notch fiducial bisector.

5.3.2 The primary row of the matrix code symbol shall be placed toward the periphery of the wafer.

Data Matrix Field Dimensions
ECC200 - 8 rows × 32 columns

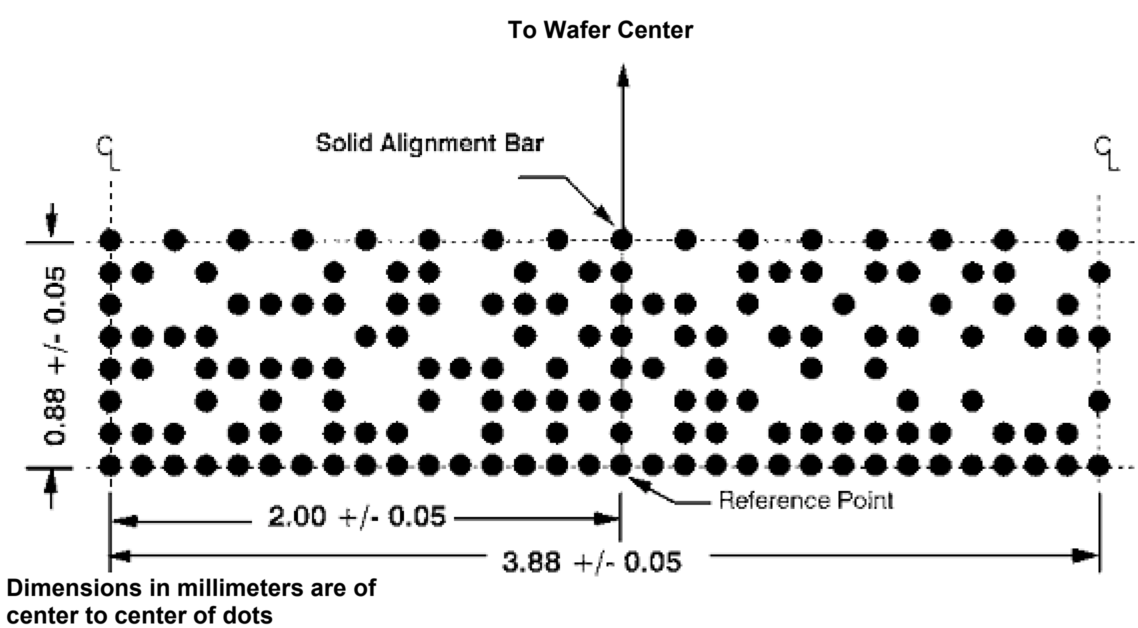

Figure 2
Data Matrix Code Fields
ECC200 - 8 rows × 32 columns

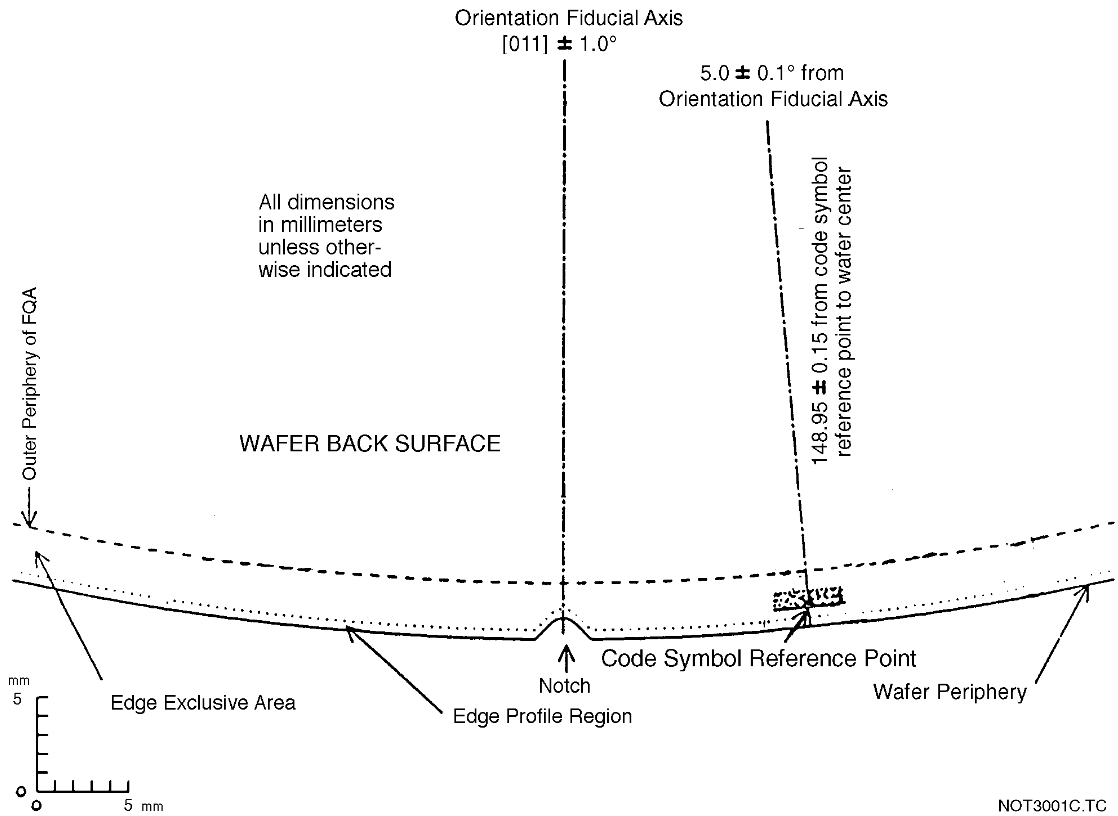

Figure 3
Data Matrix Code Symbol Location on Back Surface of Notched 300 mm Diameter Wafer

NOTE 1: The peripheries are of wafers of nominal diameter with nominal notch dimensions. The dots of the finder pattern are shown for an 8 row x 32 column data matrix code symbol with 125 µm spacing.

NOTICE: These standards do not purport to address safety issues, if any, associated with their use. It is the responsibility of the user of these standards to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require the use of copyrighted material or of an invention covered by patent rights. RVSI Acuity CiMatrix has filed a statement with SEMI asserting that the patented or copyrighted item can be used by the public for the purpose of implementing this standard without specific license and without payment of royalty or other charge. Attention is also drawn to the possibility that some elements of this standard may be subject to patented technology or copyrighted items other than those identified above. Semiconductor Equipment and Materials International (SEMI) shall not be held responsible for identifying any or all such patented technology or copyrighted items. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights and the risk of infringement of such rights are entirely their own responsibility.

SEMI T8-0698[E]
SPECIFICATION FOR MARKING OF GLASS FLAT PANEL DISPLAY SUBSTRATES WITH A TWO-DIMENSIONAL MATRIX CODE SYMBOL

[E] This document was modified in April 2000 to clarify patent issues. Changes were made to the notice at the end of this document.

1 Purpose

1.1 This specification is intended to provide a marking symbology that can be used to mark glass flat panel display (FPD) substrates within the fixed quality area of the edge exclusion area of the substrate.

2 Scope

2.1 This specification defines the geometric and spatial relationships and content (including the error checking and correcting code) of rectangular two-dimensional (2-D), machine-readable, binary Data Matrix symbology for front-surface or back-surface marking of glass FPD substrates (sometimes called "motherglass" substrates) which comply with the edge specifications of SEMI D12. It may be used in conjunction with the alphanumeric marking codes specified in SEMI M12 and SEMI M13 or the bar code specified in SEMI T1.

2.2 Although this specification does not specify the marking techniques that may be employed when complying with its requirements, it is assumed that the symbol will be obtained by laser scribing individual dots. A survivability experiment executed by the United States Display Consortium found such marks suitable.

NOTE: Other techniques could include resist exposure and grit blasting.

2.3 Data Matrix symbology is applicable to a broad range of FPD products including virgin substrates, processed and patterned substrates, panel assemblies, and displays. An application note describes the application of Data Matrix symbology to individual panel sections contained within a multi-panel motherglass substrate. The format and algorithms of this code are based on two-dimensional symbology specified in AIM International Symbology Specification - Data Matrix.

3 Uniform Code Council, 8163 Old Yankee Road, Dayton, Ohio 45458

4.6 *cell center point, of an array* — the point at which the centerline of a row intersects the centerline of a column.

4.7 *cell spacing, of an array* — the (equal) vertical or horizontal distance between the cell center points of contiguous cells.

4.8 *center line, of a row or column* — the line positioned parallel to, and spaced equally between, the boundary lines of the row or column.

4.9 *central area, of a cell* — the area enclosed by a circle centered at the cell center point; used by code readers to sense the binary value of the cell.

4.10 *data matrix code symbol* — a two-dimensional array of square cells arranged in contiguous rows and columns. In certain ECC200 symbols, data regions are separated by alignment patterns. The data region is surrounded by a finder pattern (AIM International Symbology Specification - Data Matrix).

4.11 *dot* — a localized region with a reflectance which differs from that of the surrounding surface.

NOTE 1: To assure reading efficiency, a minimum contrast of 30% is required between the reflectance value of a dot and the surrounding substrate surface. Various densitometers can provide such measurements non-destructively.

4.12 *dot misalignment, within a cell* — the distance between the physical center point of a dot and the cell center point.

4.13 *finder pattern, of a data matrix code symbol* — a perimeter to the data region. Two adjacent sides contain dots in every cell; these are used primarily to define physical size, orientation, and symbol distortion. The two opposite sides are made up of cells containing dots in alternate cells (AIM International Symbology Specification - Data Matrix).

4.14 *reference point, of a data matrix code symbol* — the physical center point of a cell common to a designated row and column, used to identify the physical location of the symbol on the object being marked with the symbol.

NOTE 2: The reference point is at a fixed location on the object. Different cells may be chosen as the reference point, depending on the desired orientation of the symbol on the object and on the size variability of the symbol. The particular cell to be used as the reference point must be specified for each application.

5 Ordering Information

5.1 Purchase orders for substrates furnished to this specification shall include the following items:

5.1.1 *Message Characters*

5.1.1.1 Quantity (15 to *nn*, where *nn* is 16–46, and depends on the character set to be encoded [see Table 2]).

5.1.1.2 Content of Message Characters 16 and up, if present.

6 Requirements

6.1 *Shape and Size of the Data Matrix Code Symbol*

6.1.1 *Data Matrix Code Symbol Dimensions*

6.1.1.1 Each rectangular matrix code symbol shall be composed of an array of 8 to 16 rows and 32 to 46 columns (see Table 1 and Figure 1) as defined in AIM International Symbology Specification - Data Matrix. It may contain an alignment bar.

6.1.1.2 Cell spacing shall be 125 µm, center to center.

6.1.2 *Dot Size* — the nominal shape of the dot produced in the matrix may be circular or square. Its diameter or edge length shall be 100 ± 10 µm.

6.1.3 *Border Rows and Columns (see Figure 3)*

6.1.3.1 One border row and one border column shall contain a dot in each cell. These are identified as the primary border row and the primary border column. These are used by the code reader to determine the orientation of the matrix.

6.1.3.2 The opposing (secondary) border row and column shall contain dots in alternating cells.

6.1.3.3 For these rectangular matrix code symbols, the reference point of the symbol shall be the physical centerpoint of the cell common to the primary border row and the primary border column.

6.1.4 The maximum allowable dot misalignment within a cell is 20 µm. This ensures that a minimum size dot covers a cell central area of radius 25 µm.

6.2 *Content of the Data Matrix Code Symbol*

6.2.1 Each rectangular matrix code symbol shall contain between 15 and 46 message characters, together with the error checking and correcting (ECC) 200 code characters, encoded in accordance with AIM International Symbology Specification - Data Marix.

6.2.2 The message characters may include any of those designated as “mostly upper case” in Table 5 and Annex K of AIM International Symbology Specification - Data Marix. 8-bit characters may also be encoded with reduced field capacity (see Table 3). The first 15 message characters shall contain two elements:

a. a vendor-assigned 8-character substrate identification code, followed by

b. a 7-character vendor identification code as defined by UCC. These are a six-digit company identification, preceded by a zero (0).

6.2.2.1 The remaining message characters, if any, shall contain information as agreed between the vendor and user. This may require field identifiers and field concatenators (see ANSI MH10.8.2).

6.3 *Location of the Data Matrix Code Symbol*

6.3.1 With the substrate positioned front surface up and with the orientation corner toward the operator and to the operator's left, the reference point of the data matrix code symbol shall be placed toward the orientation corner as specified in Table 3.

6.3.2 The 12 row × 26 column rectangular 2-D matrix code symbol shall be placed entirely outside the fixed quality area (FQA) and within a nominal edge exclusion area of 10 mm. Large symbols will extend toward the substrate center and perpendicular to the substrate edges. (See Table 1 for field dimensions.)

6.3.3 The primary row of the symbol shall be parallel to the adjacent edge of the substrate ± 10.0°. The primary column of the symbol shall be nominally perpendicular to the same edge. The symbol shall lie between these two edges and the FQA (see Figures 4 and 5). The reference point of the symbol shall be located 4.0 ± 1.0 mm from the adjacent edge of the substrate.

Table 1 2-D Data Matrix Code Symbol Dimensions

Rectangular Array Spacing	*# of Cells in Row*	*# of Cells in Column*	C_1 *(mm)*	R_1 *(mm)*	C_2 *(mm)*	R_2 *(mm)*
125 µm	12	26	1.375	3.125	1.500	3.250
	12	32	1.375	4.375	1.500	4.500
	16	36	1.875	4.375	2.000	4.500

Table 2 Message Character Count in Rectangular Arrays for Use on FPD Substrates

# of Cells in Row and Column		*12 Rows × 26 Columns*	*12 Rows × 36 Columns*	*16 Rows × 36 Columns*
Maximum # of Message Characters	8-bit	N/A	20	30
	Mostly upper-case	22	31	46

Table 3 Location of 2-D Matrix Code Symbol Substrate Back Surface Up, Orientation Corner Toward the Operator and Toward the Operator's Left

Type of Array	*Reference Point*	*Location of Reference Point*
Rectangular	Common cell of primary border row and column	*4.0 ± 1.0 mm from the nominal edge of the substrate and toward the substrate orientation corner.

* The rows of the rectangular 2-D matrix code symbol are parallel to the X-edge of a substrate whose orientation corner is in the *1,1,1* orientation or the *2, -1, 0* orientation as described in SEMI D4.

APPENDIX 1
PLACEMENT OF DATA MATRIX CODES ON DISPLAY SECTIONS OF FLAT PANEL DISPLAY SUBSTRATES

NOTE: This appendix was approved as an official part of SEMI T8, but the recommendations in this appendix are optional and are not required to conform to this standard.

A1-1 The following suggests one way in which individual display sections could be marked while still a part of the motherglass substrate. Figure A1-1 illustrates a six-up display layout on a 550 × 650 mm substrate.

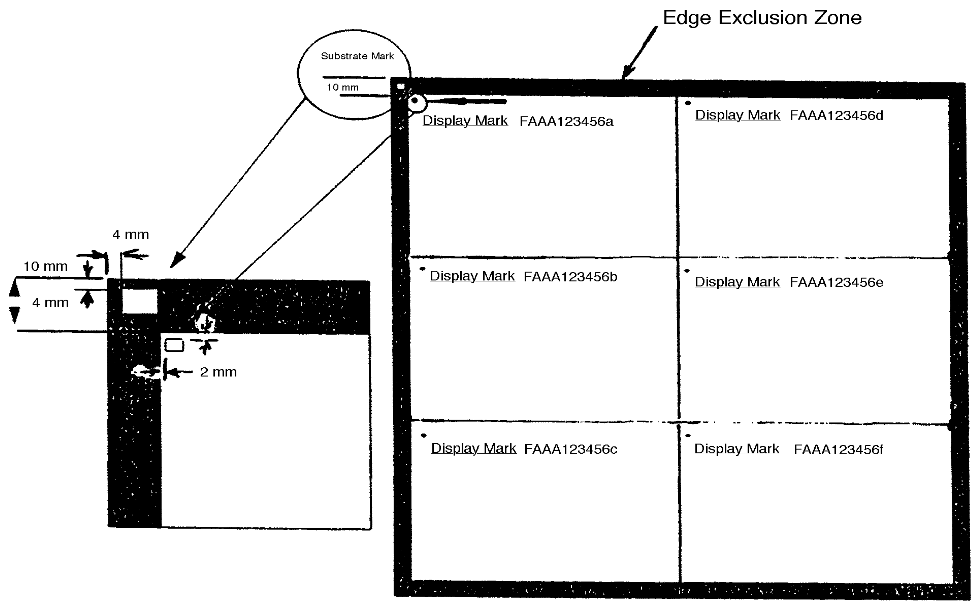

Figure A1-1
An Example of Mark Field Locations in Individual Display Sections within a "Motherglass" Substrate

A1-2 The Substrate ID location falls within the edge exclusion area as detailed in Figure 4. In this example, all ID fields are located on the back (non-pattern) surface. Placing them on the same surface as the substrate mark can simplify ID reading during fabrication. Their location on the non-pattern surface could allow ID reading of the outside surface of a display after assembly.

A1-3 The axes of the individual display IDs are parallel to the substrate ID axes. Each display ID is located adjacent to a display corner. The locations of each ID field are given.

NOTE: This example does not constitute a recommended usage, but is intended to assist users in developing ID locations suitable for their operations.

SEMI T9-0200[E]

SPECIFICATION FOR MARKING OF METAL LEAD-FRAME STRIPS WITH A TWO-DIMENSIONAL DATA MATRIX CODE SYMBOL

This specification was technically approved by the Global Traceability Committee and is the direct responsibility of the North American Traceability Committee. Current edition approved by the North American Traceability Committee on December 15, 1999. Initially available on SEMI OnLine January 2000; to be published February 2000. Originally published in 1998; previously published September 1999.

[E] This document was modified in April 2000 to clarify patent issues. Changes were made to the notice at the end of this document.

1 Purpose

1.1 This specification provides a marking symbology that can be used to mark metal lead-frame strips.

2 Scope

2.1 This specification defines the geometric and spatial relationships and content (including the error checking and correcting code) of rectangular two-dimensional (2-D), machine-readable, binary Data Matrix symbology for front-surface marking of metal lead-frame strips (also called “strips”). It may be used in conjunction with the alphanumeric marking codes specified in SEMI M12 and SEMI M13 or the bar code specified in SEMI T1.

2.2 This specification defines a 22-character default message that is included in all marks, and option for up to 50 additional characters, for a total of 72 message characters. An optional shorter message contains 12 to 16 message characters; the resulting square field is narrower but taller than the 22-character rectangular one.

2.3 This specification provides a suggested location for the code symbol. It also provides guidelines for specifying other code locations when the suggested location is not suitable for an application.

2.4 Although this specification does not specify the marking techniques that may be employed when complying with its requirements, it is assumed that the symbol will be obtained by laser scribing individual dots.

NOTE 1: A mark survivability experiment is being conducted by the SEMI North American Traceability committee. A report is available from SEMI: request “Leadframe Mark Survivability Report” dated February, 1999.

2.5 Data Matrix symbology is applicable to a broad range of lead-frame materials including copper and Alloy 42 in both bare and plated conditions. The format and algorithms of this code are based on two-dimensional symbology specified in AIM International Symbology Specification - Data Matrix.

2.6 This specification supports EIA Package Marking Specification by enabling individual die tracking in the manufacturing steps between die attach and device packaging marking.

NOTE 2: Marking of each die, while in wafer form, prior to dicing, could also accomplish this end.

2.7 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the users of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

4 Terminology

4.1 *alignment bar, of a data matrix code symbol* — a solid line of contiguous filled cells abutting a line of alternatively filled and empty cells [AIM International Symbology Specification - Data Matrix].

4.2 *binary values* — a dot in the substrate surface indicates the binary value 1. The absence of a dot, or a smooth surface surrounding a cell center point, indicates the binary value 0.

4.3 *border column* — the outermost column of a data matrix code symbol. This column is a portion of the finder pattern.

4.4 *border row* — the outermost row of a data matrix code symbol. This row is a portion of the finder pattern.

4.5 *cell, of a data matrix code symbol* — the area within which a dot may be placed to indicate a binary value.

4.6 *cell center point, of an array* — the point at which the centerline of a row intersects the centerline of a column.

4.7 *cell spacing, of an array* — the (equal) vertical or horizontal distance between the cell center points of contiguous cells.

4.8 *center line, of a row or column* — the line positioned parallel to, and spaced equally between, the boundary lines of the row or column.

4.9 *central area, of a cell* — the area enclosed by a circle centered at the cell center point; used by code readers to sense the binary value of the cell.

4.10 *data matrix code symbol* — a two-dimensional array of square cells arranged in contiguous rows and columns. In certain ECC200 symbols, data regions are separated by alignment patterns. The data region is surrounded by a finder pattern [AIM International Symbology Specification - Data Matrix].

4.11 *dot* — a localized region with a reflectance which differs from that of the surrounding surface.

NOTE 5: To assure reading efficiency, a minimum contrast of 30% is required between the reflectance value of a dot and the surrounding substrate surface. Various densitometers can provide such measurements nondestructively.

4.12 *dot misalignment, within a cell* — the distance between the physical center point of a dot and the cell center point.

4.13 *finder pattern, of a data matrix code symbol* — a perimeter to the data region. Two adjacent sides contain dots in every cell; these are used primarily to define physical size, orientation, and symbol distortion. The two opposite sides are made up of cells containing dots in alternate cells [AIM International Symbology Specification - Data Matrix].

4.14 *orientation corner, of a lead-frame strip* — the strip corner used to assure correct die assembly orientation. It is denoted by an identification mark.

4.15 *reference point, of a data matrix code symbol* — the physical center point of a cell common to a designated row and column, used to identify the physical location of the symbol on the object being marked with the symbol.

NOTE 6: The reference point is at a fixed location on the object. Different cells may be chosen as the reference point, depending on the desired orientation of the symbol on the object and on the size variability of the symbol. The particular cell to be used as the reference point must be specified for each application.

4.16 *quiet zone* — an unmarked background area that surrounds the entire code symbol.

5 Ordering Information

5.1 Purchase orders for lead-frame strips furnished to this specification shall include the following items:

5.1.1 Message Characters

5.1.1.1 Quantity (12 to *mm*, where *mm* = 13 to 16; or 22 to *nn*, where *nn* is 23 to 72).

5.1.1.2 Content of Message Characters 13 to 16, or 23–up, if present.

5.1.2 Location of Mark, if different from Section 6.3

6 Requirements

6.1 *Shape and Size of the Data Matrix Code Symbol*

6.1.1 *Data Matrix Code Symbol Dimensions*

6.1.1.1 Each rectangular matrix code symbol shall be composed of an array of 12 to 16 rows and 26 to 48 columns as defined in AIM International Symbology Specification - Data Matrix.

6.1.1.2 Each square matrix code symbol shall be composed of an array 16 rows and 16 columns.

6.1.1.3 Table 1 defines the field dimensions and maximum number of message characters for each of the five available combinations of rows and columns.

Table 1 2-D Data Matrix Code Symbol Dimensions

Cell Spacing (µm)	*# of Cells in Row*	*# of Cells in Column*	*C1*	*R1*	*C2*	*R2*	*# of Message Characters, Maximum*
			(mm)				
100	12	26	1.10	2.50	1.20	2.60	22
	12	36	1.10	3.50	1.20	3.60	31
	16	36	1.50	3.50	1.60	3.60	46
	16	48	1.50	4.50	1.60	4.80	72
	16	16	1.50	1.50	1.60	1.60	16

6.1.1.4 Cell spacing shall be 100 µm, center to center.

6.1.2 *Dot Size* — The nominal shape of the dot produced in the matrix may be circular or square. Its diameter or edge length shall be 100 ± 10 µm.

6.1.3 *Border Rows and Columns* (see Figure 3)

6.1.3.1 One border row and one border column shall contain a dot in each cell. These are identified as the primary border row and the primary border column. These are used by the code reader to determine the orientation of the matrix.

6.1.3.2 The opposing (secondary) border row and column shall contain dots in alternating cells.

6.1.3.3 For these rectangular and square matrix code symbols, the reference point of the symbol shall be the physical centerpoint of the cell common to the primary border row and the primary border column.

6.1.4 The maximum allowable dot misalignment within a cell is 20 µm. This ensures that a minimum size dot covers a cell central area of radius 25 µm.

6.2 *Content of the Data Matrix Code Symbol*

6.2.1 Each matrix code symbol shall contain between 12 and 72 message characters, together with the error checking and correcting (ECC) 200 code characters, encoded in accordance with AIM International Symbology Specification - Data Matrix.

6.2.2 The message characters may include any of those designated as “mostly upper case” in Table 5 and Annex K of AIM International Symbology Specification - Data Matrix. The message characters are contained in a single field that contains multiple sub-fields (see Table 2). In the absence of a character at any assigned location, a dash (‘-’) shall be used.

6.2.2.1 The standard message code shall contain 22 or more characters. The first 22 characters shall be contained in sub-fields 1 through 6 whose content is listed in Table 2. The number of message characters in each of these sub-fields is fixed. Other sub-fields may be added to the message subject to Section 6.2.2.2. To save space or for other reasons, a condensed message code may be used as an alternative. Refer to Section 6.2.2.3.

6.2.2.2 Characters 23–up, if present, shall contain information as agreed upon between supplier and user. This may require field identifiers and field concatenators (see ANSI MH10.8.2).

6.2.2.3 The condensed message code shall contain 12 to 16 characters. The first 12 characters shall be contained in sub-fields 1 through 3, as listed in Table 3. The number of message characters in each of these sub-fields is fixed. Content of sub-field(s) for characters 13 through 16, if present, are to be agreed upon between supplier and user.

6.2.3 Sub-fields 2 and 3 in Table 2 and Table 3 are intended to provide a unique identification number for each strip from a given supplier.

Table 2 Sub-Field Message Characters in Rectangular Arrays for Use on Lead-Frame Strips (Standard Message Code)

Sub-Field Content		*Character Symbols*	*Number of Characters*
#	*Symbol Content*		
1	Field Identifier	IT (See NOTE 1.)	2
2	Traceability Number: Coil S/N	vendor assigned (See NOTE 2.)	3
3	Traceability Number: Strip ID	vendor assigned (See NOTE 2.)	7
4	Concatenation Symbol	+	1
5	Field Identifier	3V (See NOTE 1.)	2
6	Supplier ID	UCC/EAN coding	7
7	Optional Information	Vendor-user agreed	0 to 50
	Total		22 to 72

NOTE 1: These field identifiers are described in ANSI-FACT-1.

NOTE 2: Lead-frame strip suppliers

Table 3 Sub-Field Message Characters in 16 x 16 Arrays for Use on Lead-Frame Strips (Condensed Message Code)

#	*Sub-Field Content*	*Character Symbol*	*Number of Characters*
1	Field Identifier	IT (See NOTE 1.)	2
2	Traceability Number: Coil S/N	Vendor-assigned (See NOTE 2.)	3
3	Traceability Number: Strip ID	Vendor-assigned (See NOTE 2.)	7
4	Optional Information	Vendor-user agreed	0 to 4
	Total Characters		12 to 16

NOTE 1: These field identifiers are described in ANSI-FACT-1.

NOTE 2: Lead-frame strip suppliers

6.3 *Location of the Data Matrix Code Symbol*

6.3.1 With the strip positioned front surface up and with the strip orientation corner away from the operator and to the operator's right, the reference point of the data matrix code symbol shall be placed adjacent to the leading edge of the strip, and toward the strip orientation corner as specified in Table 4 and Figure 5.

6.3.2 The primary row of the symbol shall be parallel to the adjacent edge of the substrate ± 10.0°. The primary column of the symbol shall be nominally perpendicular to the same edge. The reference point of the symbol shall be located 0.3 mm minimum, from the adjacent strip rail, 2.0 mm minimum, from the adjacent strip end and toward the strip orientation corner.

Table 4 Location of 2-D Matrix Code Symbol Strip Front Surface Up, Strip Orientation Corner Away from the Operator and Toward the Operator's Right

Type of Array	*Reference Point*	*Location of Reference Point*
Rectangular	Common cell of primary border row and column.	A ± 0.1 mm from the nominal edge of the rail, B ± 0.5 mm from the adjacent strip end and toward the strip orientation corner (see Section 6.3.4).

6.3.3 For the default location for the symbol, A = 0.4 mm and B = 2.5 mm.

6.3.4 This location may not be acceptable for all lead strips. The mark may be placed in other locations provided that the following condition is maintained:

1. A zone 0.3 ± 0.1 mm wide and clear of marks and other surface features is maintained around the entire data matrix code (sometimes called "quiet zone").

6.3.5 Refer to Figure 6 for examples of acceptable data matrix code locations on several lead-frame designs.

NOTICE: SEMI makes no warranties or representations as to the suitability of the standards set forth herein for any particular application. The determination of the suitability of the standard is solely the responsibility of the user. Users are cautioned to refer to manufacturer's instructions, product labels, product data sheets, and other relevant literature respecting any materials mentioned herein. These standards are subject to change without notice.

The user's attention is called to the possibility that compliance with this standard may require the use of copyrighted material or of an invention covered by patent rights. RVSI Acuity CiMatrix has filed a statement with SEMI asserting that the patented or copyrighted item can be used by the public for the purpose of implementing this standard without specific license and without payment of royalty or other charge. Attention is also drawn to the possibility that some elements of this standard may be subject to patented technology or copyrighted items other than those identified above. Semiconductor Equipment and Materials International (SEMI) shall not be held responsible for identifying any or all such patented technology or copyrighted items. By publication of this standard, SEMI takes no position respecting the validity of any patent rights or copyrights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of any such patent rights or copyrights and the risk of infringement of such rights are entirely their own responsibility.

SEMI T10-0701
TEST METHOD FOR THE ASSESSMENT OF 2D DATA MATRIX DIRECT MARK QUALITY

This specification was technically approved by the Global Traceability Committee and is the direct responsibility of the North American Traceability Committee. Current edition approved by the North American Traceability Committee on March 20, 2001. Initially available on SEMI at www.semi.org May 2001; to be published July 2001.

1 Purpose

1.1 This standard is intended to define the methodology for the assessment of 2D Data Matrix direct mark quality.

2 Scope

2.1 This standard defines assessment criteria, metrology methods, and assessment reporting procedures as applied to 2D Data Matrix code direct marks on semiconductor related materials. Application specifications, which refer to this standard, may further limit its scope to more specific requirements of a particular application.

2.2 This standard does not purport to address safety issues, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3 Limitations

3.1 This standard will not specifically address the quality assessment of paper-printed labels and will be limited to the usage of the Data Matrix symbology as defined by the AIMI standard.

3.2 This standard will not specify the resulting minimum, maximum or nominal values of any direct mark assessment method which would be considered acceptable for a 2D Data Matrix direct mark application. Application specifications may define these values with reference to this standard.

4 Referenced Standards

4.1 *AIM International Technical Specification*[1]

AIMI Uniform Symbology Specification - Data Matrix

5 Terminology

5.1 Definitions of terms relating to 2D Data Matrix direct mark assessment are as follows:

5.1.1 *alternating pattern of a Data Matrix code symbol* — a line of alternately filled and unfilled cells indicative of the cell spacing along one of the major axes of the Data Matrix symbol (see Figure 1).

5.1.2 *binary value* — a mark in the substrate surface indicates the binary value of one. The absence of a mark, or a smooth surface surrounding a cell center point, indicates the binary value of zero.

5.1.3 *cell, of a Data Matrix symbol* — the area within which a marking may be placed to indicate a binary value. The cell is the smallest element of a two-dimensional Data Matrix symbol. The cell shape is generally quadrilateral, typically rectangular and ideally square.

5.1.4 *cell center point, of a Data Matrix symbol* — the point at which the centerline of a matrix row intersects the centerline of a column.

5.1.5 *cell size, of a Data Matrix symbol* — the number of image pixels within a Data Matrix symbol cell. Since the cell is generally rectangular in shape, the resolution is specified in both the horizontal and vertical directions of the cell.

5.1.6 *cell spacing, of a Data Matrix symbol* — the vertical or horizontal distance between the cell center points of contiguous cells.

5.1.7 *centerline, of a row or a column* — the line positioned parallel to, and spaced equally between, the boundary lines of the row or column.

5.1.8 *edge* — the location of a significant change in pixel brightness values between regions. It is the point(s) that has the greatest amount of contrast difference (change in intensity values) between pixels.

5.1.9 *edge detection method* — a method whereby the location of an edge in an image is determined.

5.1.10 *error correction* — mathematical techniques, which reconstruct the original information, based upon the remaining data in a damaged or poorly marked code. Reed Solomon and convolution are two such techniques.

1 AIM International, Inc., 11860 Sunrise Valley Drive, Suite 100, Reston, VA 20191, tel 703.391.7621, fax 703.391.7624

NOTE 1: Error correction techniques are described extensively in AIMI Uniform Symbology Specification - Data Matrix.

5.1.11 *finder pattern, of a Data Matrix symbol* — a perimeter to the data region. Two adjacent sides contain marks in every cell: these are used primarily to define physical size, orientation and symbol distortion. This is often referred to as the L finder pattern. The two opposite sides are made up of cells containing marks in alternate cells (see Figure 1).

5.1.12 *grayscale value* — the assignment of a digital value to a degree of light intensity. The shades of gray are used by a computer to reconstruct an image. A common scale is 256 shades of gray, with 0 being black and 255 being white.

5.1.13 *histogram* — a graphic representation of a frequency distribution of pixel values within an area of interest in a two-dimensional grayscale digital image. The horizontal axis of the graph represents the range of possible grayscale values in the image. The vertical axis of the graph represents the frequency of occurrence of each grayscale value in the area of interest (see Figure 2).

5.1.14 *image coordinates* — locations in a two-dimensional digital image are referenced by a two-dimensional orthogonal coordinate system. The datum for the coordinate system is in the upper-left corner of the image. The horizontal axis or x-axis is located along the top of the image, with increasing positive values from left to right in the image. The vertical axis or y-axis is located along the left side of the image, with increasing positive values from top to bottom in the image.

5.1.15 *mark* — a cell or area of a Data Matrix symbol, which has been marked, meaning the substrate has been altered by the marking process so as to significantly alter its contrast when imaged. Also can refer to an entire Data Matrix symbol that has been applied in rows and columns on a substrate by a marking process.

5.1.16 *pixels* — picture elements. In a two-dimensional digital image, pixels are individual elements to which a grayscale value is associated. The combination of grayscale values for each pixel and its respective location in a two-dimensional plane form a digital representation of a real scene.

5.1.17 *pixel resolution* — the precision in pixels at which all measurements are performed. The maximum pixel resolution shall be 1 pixel.

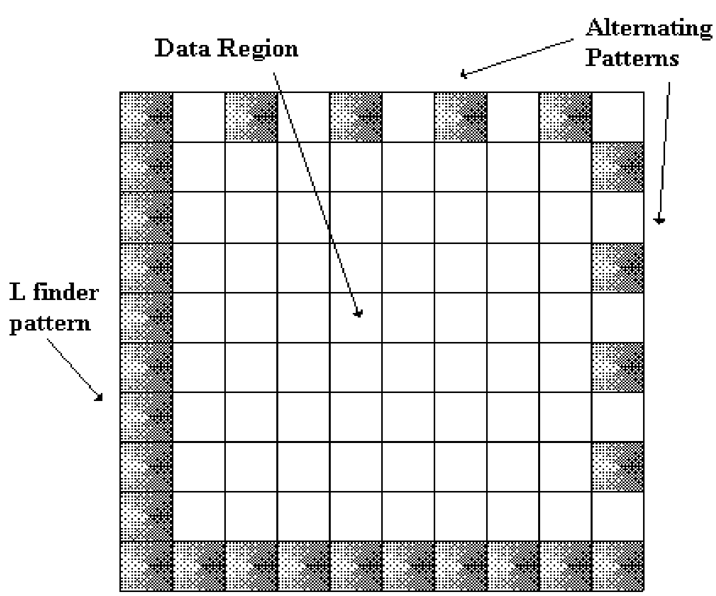

Figure 1
Data Matrix Symbol

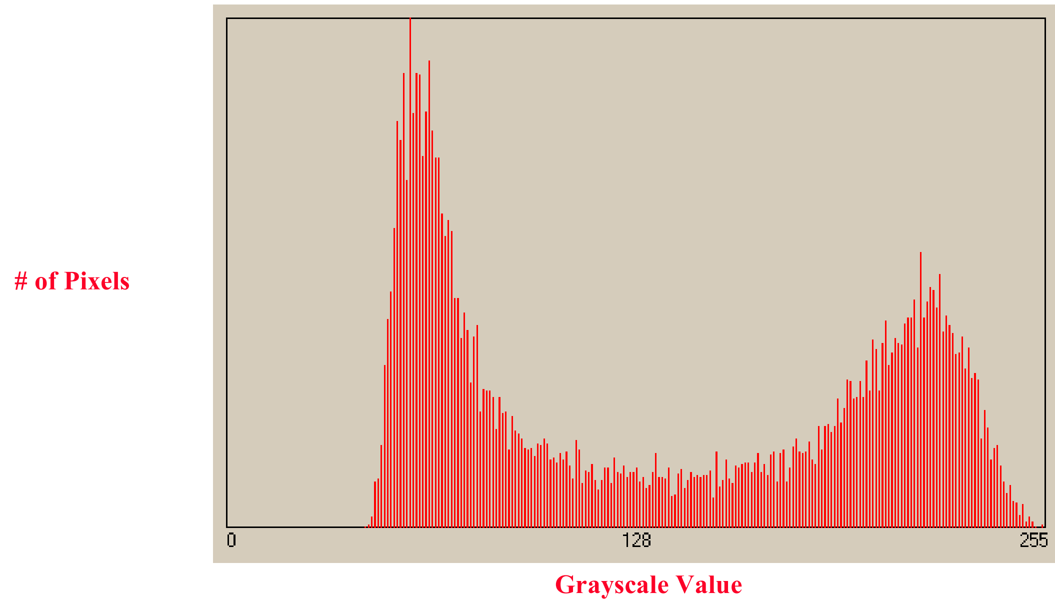

Figure 2
Pixel Histogram

5.1.18 *quiet zone* — areas of space surrounding the machine-readable symbol. Quiet zone requirements may be found in application and symbology specifications. Sometimes called "Clear Area" or "Margin."

5.1.19 *space* — an unmarked cell or area of a Data Matrix Symbol.

5.1.20 *symbol* — a machine-readable pattern comprised of a quiet zone, finder pattern, symbology characters (which include special functions and error detection and/ or correction characters) required by a particular symbology.

5.1.21 *symbol contrast* — the difference in grayscale values between the marked and unmarked areas of a Data Matrix symbol.

6 Summary of Method and Requirements

6.1 *Test Image*

6.1.1 A test image of the mark shall be obtained in a configuration that mimics the typical reading configuration for that mark, at substantially the same resolution, illumination, optical focus, image exposure, gain or other image signal preprocessing settings that are used during reading. Individual applications may dictate a specific wavelength or color temperature and spatial construction of illumination, image resolution, optical focus, image exposure, etc. The mark/reader configuration shall be consistent to the extent that repeatable results can be obtained from a single sample over many instances of one mark/reader configuration.

6.1.2 The intent of the assessment procedure is to regard a test image from the actual mark/reader configuration as the source for all assessment. Therefore, the assessment criteria and the algorithms used to carry out each assessment should be resident in the actual reading system or equivalent that is used to read the mark. If a separate assessment or verification system, which has different illumination characteristics, resolution, etc., is used, uncorrelated results may occur.

6.2 *Edge Detection Method*

6.2.1 Many of the assessment procedures depend significantly on the type of edge detection method that is employed to locate edges in the test image which define the bounds of the entire Data Matrix symbol as well as individual cells within the matrix. The edge detection method used should be consistent throughout the assessment process.

7 Procedure

7.1 *Location and Orientation of the Data Matrix Symbol*

7.1.1 *Data Matrix Location Descriptors*

7.1.1.1 The implementation of the symbol quality assessment depends on knowledge of the location and orientation of the Data Matrix symbol in the image, which consists of the 4 image coordinate values of the matrix corner points, P1, P2, P3, and P4 (see Figure 3). In addition, the number of rows M and the number of columns N in the Data Matrix symbol is also required (see Figure 3). Determine the image coordinate values and the number of rows and columns using a pre-processing decoding procedure resident in the reading system. Should this process either fail or not be available, determine these values by inspection of the test image. Report the coordinate values of each matrix corner point and the number of rows and columns.

7.1.2 *The Data Matrix Grid*

7.1.2.1 Based on the location of the 4 matrix corner points and the number of rows and columns in the matrix establish a geometrical 2 dimensional matrix grid. Establish line segment P1P2 using points P1 and P2, line segment P2P3 using P2 and P3, line segment P3P4 using P3 and P4, and finally line segment P1P4, using P4 and P1. Divide the number of rows M into the P1P2 line segment, producing M equally sized line segments. Divide the number of rows M into the P3P4 line segment producing a similar result. Divide the number of columns N into P1P4 line segment, producing N equal sized line segments. Divide the number of columns N into the P2P3 line segment, producing a similar result. Connect the corresponding new line segment endpoints between P1P2 and P3P4. Connect the corresponding new line segment endpoints between P1P4 and P2P3. This results in a 2 dimensional matrix grid similar to that shown in Figure 3. This grid is generally quadrilateral in shape, practically rectangular and ideally square.

7.1.3 *Data Matrix Cell Center Points*

7.1.3.1 Determine the ideal geometrical center points in each matrix cell in the following manner. Establish a new set of points at the bisection of each row and column line segment used to form the matrix grid. Form line segments between each corresponding row bisection point in P1P2 and P3P4. Do the same for the column bisection points in P1P4 and P2P3. The intersection points between this new set of lines in each matrix cell is the ideal geometrical matrix cell center point (see Figure 4).

Matrix Cell Center Locations

7.2 *Symbol Contrast*

7.2.1 Symbol Contrast measures the distinctiveness of the two reflective states in the symbol, namely light and dark. Many aspects of the mark/reader configuration affect the resulting symbol contrast in the image.

7.2.2 Within the grayscale image, select all of the image pixels, which fall within the area of the symbol, extending outward to the limits of any required quiet zones. Sort the selected pixels by their reflectance values into a histogram. Calculate the arithmetic mean of the reflectance histogram. Use this mean value to separate the reflectance histogram into 2 sections or sub-histograms, which represent approximate reflectance histograms for the dark and light contrasts of the symbol. Calculate the arithmetic mean of each sub-histogram. The lower grayscale value of the two means represents the dark grayscale value G_D and the higher value represents the light grayscale value G_L. Use these two grayscale values to calculate a new symbol contrast. The difference of the grayscale levels divided by the full range of grayscale (255 in the case of 8 bit A/D Sampling) is the Symbol Contrast. Report the Symbol Contrast value.

$$SC = \frac{G_L - G_D}{\text{Grayscale Range}(255)} \times 100\% \qquad (1)$$

7.3 *Symbol Contrast Signal to Noise Ratio (SNR)*

7.3.1 The Symbol Contrast Signal to Noise Ratio (SNR) is a relative measure of the symbol contrast (signal) to the maximum deviation in the light or dark grayscale level in the symbol (noise). Using the sub-histograms and the two grayscale values G_L and G_D found in the Symbol Contrast calculation, calculate the deviation of each sub-histogram about each respective grayscale value. Two values will result: the deviation of light pixels D_L and the deviation of dark pixels D_D. Calculate a symbol contrast difference in grayscale value using the grayscale values. Divide this contrast difference by the maximum deviation calculated for the individual light and dark sections of the histogram. This ratio is the Symbol Contrast SNR. Report the symbol contrast SNR.

$$\text{Symbol Contrast SNR} = \frac{G_L - G_D}{\text{Max}(D_L, D_D)} \qquad (2)$$

7.4 *Mark Growth*

7.4.1 Mark Growth is concerned with tracking the tendency of a marking system to over or under mark the symbol. This is a size comparison between the actual marked cells vs. their nominal size. Changes in mark growth can be indicative of changes in the marking process or substrate characteristics or changes in the reader configuration, such as illumination or optical focus.

7.4.2 Within the grayscale image, based upon the matrix coordinates and the number of rows and columns in the matrix, determine a scanline of pixels which bisects the horizontal alternating pattern and determine a scanline which bisects the vertical alternating pattern of the matrix (Figure 3). Scan along each alternating pattern, generating a cross-sectional grayscale profile of each alternating pattern as shown in Figure 5. Determine the location of each edge within the alternating patterns locally, using an appropriate edge detection method. Based upon the edge locations, compute the width of each matrix cell in the horizontal alternating pattern in the direction of the horizontal scanline. Also, compute the height of each matrix cell in the vertical alternating pattern in the direction of the vertical scanline. Separate the mark and space cell widths and compute the median space cell width (SCW) and the median mark cell width (MCW). Horizontal Mark Growth (HMG) is computed as:

$$HMG = \frac{\text{Med}(MCW)}{\text{Med}(MCW) + \text{Med}(SCW)} \times 100\% \qquad (3)$$

Separate the mark and space cell heights and compute the median space cell height (SCH) and the median mark cell height (MCH). Vertical Mark Growth (VMG) is computed as:

$$VMG = \frac{\text{Med}(MCH)}{\text{Med}(MCH) + \text{Med}(SCH)} \times 100\% \qquad (4)$$

Report the Horizontal Mark Growth and Vertical Mark Growth values.

7.5 *Data Matrix Cell Size*

7.5.1 The Data Matrix Cell Size expresses the average size of each cell in the matrix in pixels and is composed of a width and height component. Compute the Cell Size using the distances between corner points and the known number of rows M and the known number of columns N in the matrix (referring to Figure 3).

7.5.2 *Data Matrix Cell Width*

7.5.2.1 Compute the Data Matrix Cell Width (DMCW) using the distance between P1 and P4, dist(P1, P4), the distance between P2 and P3, dist(P2, P3) and the number of columns N as follows:

$$DMCW = \frac{\text{dist}(P1, P4) + \text{dist}(P2, P3)}{2 \times N} \qquad (5)$$

Report the Data Matrix Cell Width.

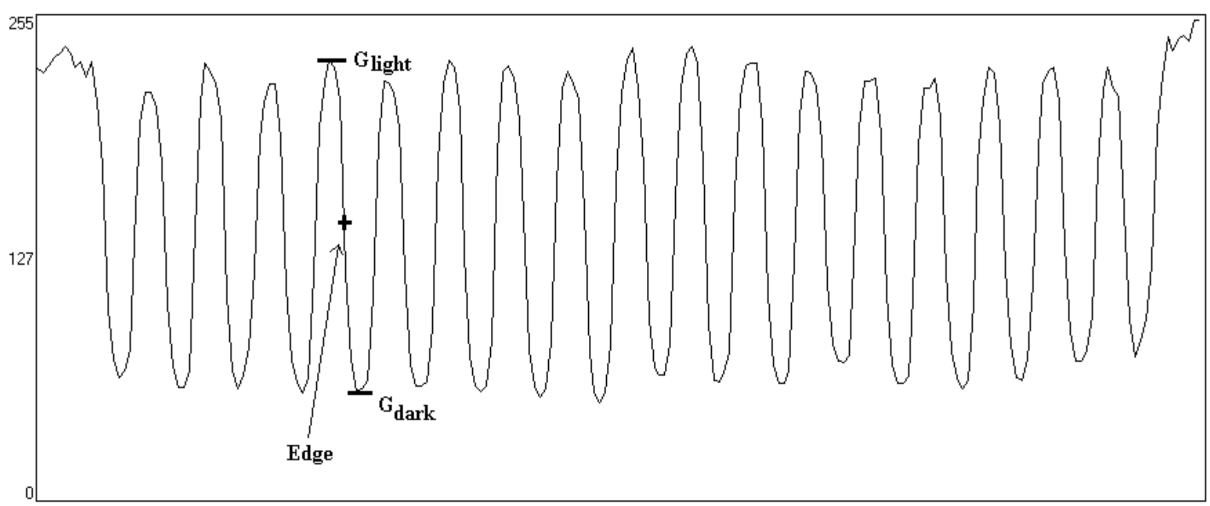

Figure 5
Mark Growth Cross-Sectional Grayscale Profile

7.5.3 *Data Matrix Cell Height*

7.5.3.1 Compute the Data Matrix Cell Height (DMCH) using the distance between P1 and P2, dist(P1,P2), the distance between P3 and P4, dist(P3,P4) and the number of rows M as follows:

$$\text{DMCH} = \frac{\text{dist(P1,P2)+dist(P3,P4)}}{2\times\text{M}} \qquad (6)$$

Report the Data Matrix Cell Height.

7.6 *Data Matrix Mark Misplacement*

7.6.1 Data Matrix Mark Misplacement measures the average misplacement of Data Matrix marks from their respective ideal Data Matrix Cell Center Points as defined in Section 7.1.3. The Mark Misplacement is measured separately in horizontal and vertical directions relative to the average width of the marks in the respective direction.

7.6.2 Using the mark cell horizontal and vertical edge locations, as determined in Section 7.4.2, compute the image coordinate of the midpoint between the edges of each mark in the corresponding horizontal and vertical directions. In the horizontal direction, for each mark calculate its misplacement MH_i as the distance between the detected midpoint and its ideal cell center point. In the vertical direction, for each mark calculate its misplacement MV_i as the distance between the detected midpoint and its ideal cell center point.

7.6.3 *Horizontal Mark Misplacement*

7.6.3.1 In the horizontal direction, for a given number of columns N, and the Data Matrix Cell Width (DMCW) as computed in Section 7.5.2, compute the Horizontal Mark Misplacement (HMM)as follows:

$$\text{HMM} = \frac{\sum_{i=1}^{n} MH_i}{n\times\text{DMCW}}\times 100\% \qquad (7)$$

where n = N/2 if N is even or n = N/2+1 if N is odd. Report the Horizontal Mark Misplacement.

7.6.4 *Vertical Mark Misplacement*

7.6.4.1 In the vertical direction, for a given number of rows M, and the Data Matrix Cell Height (DMCH) as computed in Section 7.5.3, compute the Vertical Mark Misplacement (VMM) as follows:

$$\text{VMM} = \frac{\sum_{i=1}^{m} MV_i}{m\times\text{DMCH}}\times 100\% \qquad (8)$$

where m = M/2 if M is even and m = M/2+1 if M is odd. Report the Vertical Mark Misplacement.

7.7 *Unused Error Correction*

7.7.1 The error correction capacity of Reed-Solomon decoding is expressed in the equation:

$$e + 2t \le d - p \text{ where:} \qquad (9)$$

e is the number of erasures,

t is the number of errors,

d is the number of error correction codewords,

p is the number of codewords reserved for error detection.

7.7.2 Values for d and p are defined by the AIMI Symbology Specification (often depending on symbol size), while e and t are determined during a successful decode. Compute the Unused Error Correction as follows:

$$\text{UEC} = \left(1.0 - \frac{(e+2t)}{(d-p)}\right)\times 100\% \qquad (10)$$

Report the Unused Error Correction value.

7.7.3 In symbols with more than one (e.g. interleaved) Reed-Solomon block, calculate the Unused Error Correction for each block independently and report the value for each block.

7.8 *Cell Defects and Finder Pattern Defects*

7.8.1 If the error correction capacity of the Data Matrix symbol is not exceeded then the Cell Defect measurement can be made. Because the Data Matrix symbol has been decoded, the correct binary value of each cell is known.

7.8.2 Based upon the Data Matrix Grid as defined in Section 7.1.2 (Figure 4), and the total matrix size, identify the number and location of all pixels which fall within the bounds of the Data Matrix Grid. Based upon the reflectance threshold determined by the Symbol Contrast measurement, assign a binary value to each pixel within the Data Matrix Grid. Accumulate the total number of identified image pixels, which are the incorrect binary value. Divide this number by the total number of pixels within the Data Matrix Grid.

$$\text{Cell Defects} = \frac{\#\text{ of incorrect pixels}}{\text{total }\#\text{ of pixels}}\times 100\% \qquad (11)$$

7.8.3 Finder pattern quality can be calculated in a similar manner. Based on the Data Matrix Grid as defined in Section 7.1.2 (Figure 4), determine the number and location of image pixels which fall within the bounds of the L finder pattern of the Data Matrix Grid. Using the reflectance threshold determined by the Symbol Contrast measurement, assign a binary value to each pixel within the L finder pattern. Accumulate the total number of identified image pixels, which are the incorrect binary value. Divide this number by the total number of pixels within the L finder pattern.

$$\text{F.P. Defects} = \frac{\#\text{ of incorrect pixels}}{\text{total }\#\text{ of pixels}} \times 100\% \qquad (12)$$

8 Interpretation of Results

8.1 *Result Significance*

8.1.1 The significance of the assessment results will depend on the mark/reader application. Open system applications in which multiple marker and reader systems of various types at multiple sites are used will require stricter adherence to desired mark assessment results. If the mark is intended to survive subsequent processing steps after marking which will affect mark characteristics, then reassessment may be necessary to ensure continued readability.

9 Reporting Results

9.1 *Assessment Results*

9.1.1 The results of each assessment shall be reported and listed individually.

9.2 *Additional Information*

9.2.1 The following items should also appear in the report:

- identification of the mark under assessment;
- operator identification;
- location of where the assessment was done;
- description of specific marking and reading equipment used.

9.3 *Supplemental Information*

9.3.1 Supplemental information can be reported optionally. This information provides further details about the size, content and color polarity of the Data Matrix symbol.

9.3.2 Symbol Type indicates the ECC (error correction) level of the analyzed symbol. See the AIMI Specification for details on ECC levels other than ECC 200.

9.3.3 Symbol Size indicates the total size of the matrix, including the L and alternating patterns per the AIMI specification.

9.3.4 Image Polarity can be Dark on Light or Light on Dark. The first term refers to the polarity of the L, the second the polarity of the quiet zone.

9.3.5 Encoded Data shows the printable encoded characters only. As many lines as needed will be included for larger symbols.

9.3.6 Data Codewords and Error Codewords (ECC 200 only) shows the actual encoding codewords that are contained in the symbol. Codewords, which contain errors, may be indicated or highlighted. By referring to Annex M of the AIMI Specification the exact physical location of codewords can be determined.

9.3.7 Encodation Scheme (ECC 0 through 140 only) reports the "Base" number, which relates to the density or efficiency with which the data has been encoded in the symbol. For more detailed information refer to Section 5 of the AIMI Specification.

10 Precision and Accuracy

10.1 *Pixel Resolution*

10.1.1 The pixel resolution shall be specified for all assessments. This value determines the precision, accuracy and repeatability of each resulting measurement.
